The prizes are contemptible, and indeed so poor that no one cares to send their plants or to cut their trees for the sake of winning these. Let me take Sherborne as an instance. They held their show last week, and always attract a great number of people. They have a good band, and fireworks to end up with; but as to flowers, what do you suppose they offer for Roses? Why, for twenty-four trebles (open) the first prize is £1, and to be allowed to compete for this valuable prize, unless you subscribe, you have to pay an entrance fee of 2s. 6d. Then for amateurs for twelve blooms you are offered 10s., and have to pay 2s. 6d. entrance fee also. For Gladioli similar amounts are offered. Now, as the bulbs cost from 5s. to 7s. 6d. each, it is of course not exceedingly likely that an amateur will cut his spikes and spoil his garden for the short time the Gladioli are in bloom, pay 2s. 6d. entrance fee and his railway expenses, all for the chance of winning 10s. At Exeter the other day I regret, and as a member of the committee am ashamed to say, that we fell to a lower depth still, offering

7s. 6d. as the first prize for twelve Roses—this, too, by a society that only allows subscribers of a guinea to exhibit. At Dorchester, where I was particularly requested to show, and where I sent two lots of Roses, my man could not for a long time even obtain a pass ticket, and it was only after much deliberation and with great reluctance that one was given. Mr. Corp of Oxford, who went all that way for a trumpery prize, was positively refused one, and had ultimately to go to the Secretary's house before he got one. Oliver Twist asking for more soup did not more astonish the guardians than did the equally modest request of my man for a pass ticket at my own county town. "Why, whatever shows can you have been at before to expect this?" was the question put in reply to the astounding request. "Well, most places, I think; London, Crystal Palace, Torquay, Hereford, Birmingham, Exeter, Nottingham, Huntingdon, Weston, and Taunton—in fact, everywhere except here, and this is my first and last appearance, so let me have a pass as a farewell." "Why do you show at such places?" I fancy someone may ask. Well, when you have polite letters asking you to exhibit, and you do not like to refuse, and so go at a dead loss to yourself, expecting at least decently civil treatment. But such, alas! is the exception not the rule.

I hope you will print this letter just as it is, for I feel sure it will do me no harm, as I shall not expose myself to such treatment again; and the appearance of these remarks may, perhaps, do good, by opening the eyes of the authorities of local shows as to the liberality of their treatment of exhibitors.—JOHN B. M. CAMM.

STRAWBERRIES.

My reason for discarding Black Prince is that I do not think it is worth the trouble of eating, and I certainly should never put a dish of it on my table. Keens' Seedling is a good hardy variety, but of no great quality, and did not succeed well with me; nor do I think I have ever lately eaten one in other persons' gardens that I thought worthy to be named with Sir Joseph Paxton, Lucas, or Dr. Hogg.

If the only object of growing Strawberries is to make preserves, well, by all means go in for quantity rather than quality; but Vicomtesse Héricart de Thury makes far better Strawberry jam than either Black Prince or Keens' Seedling, and the better the flavour of the fruit the better the quality of preserve. There is as much difference between Strawberry jam and Strawberry jam as there is between a pot of Green Gage preserve and one made from blue Orleans Plum. However, tastes differ; and if a kitchen gardener wishes to grow only for preserving purposes, and thinks Black Prince and Keens' Seedling will furnish the housekeeper with most pots, by all means let him do so. I never said they were worthless; I merely said I have discarded them, just as I am discarding Sir C. Napier, Souvenir de Kieff, and others, because I do not think them worth growing in my soil. I do not care, again, for mere size in fruit; there must be quality, though if combined with size, and what after all is of no little importance when set on the table, form and colour, it enhances the value of the Strawberry. La Grosse Sucrée is a beautiful Strawberry to look at, but it has not in my mind flavour enough. I am sorry to see by the last number of the *Journal of Horticulture*, Sept. 6th, that Traveller is in some soils uncertain. With me it is certainly most promising.

I do not think, as a rule, we pay sufficient attention to the quality of the leaf of the Strawberry plant, the length of footstalk, habit of development of crown, &c. Some sorts have stiff leaves or short footstalks that do not flag with the sun, and are more capable of resisting red spider and dry weather; others have soft foliage and long stalks, with spreading habits, and will not succeed in light dry soils, although in a rainy season they may make very strong growth. Sir C. Napier is one of the latter class—soft leaves, long footstalks, soft fruit, a free bearer, but—and it is a big but—inipid, rots in wet weather, burns up in dry. Dr. Hogg with me has such a tendency to make runners that it hardly ever makes good crowns, and it is almost impossible to keep the runners out off. It was curious this year to notice the difference between six beds of six different kinds all planted at the same time and treated in the same way—viz., Lucas, Sir J. Paxton, President, Filbert Pine, Dr. Hogg, and Bonne Bouche. Dr. Hogg has run all in a mass the last few weeks, and the ground has been too wet to get on to it to clear the runners, and the fine days too few to spare the time. President has made

fine runners, but also good crowns; the same of Sir J. Paxton and Lucas. Filbert Pine is a good fruit, but weak habit in my soil, and requires a stronger soil and good management. Bonne Bouche is a good sort but uncertain.

I am sure "AMATEUR, Cirencester," is right when he says with proper care and attention Strawberry beds may be made to last many years. One of mine has been in bearing for more than ten years—I think twelve, but I am not quite certain—and is only this year condemned, not because it has ceased fruiting, but because the whole quarter has to be cut up.—C. P. PEACH.

In the present season we began gathering from Black Prince the last week in June; then followed Keens' Seedling, President, Sir Joseph Paxton, Refresher, and Reeves' Eclipse. Dr. Hogg will persist in coming with a white end, giving it the appearance of an unripe fruit, which detracts from its quality, otherwise it is a noble variety and one of the best Strawberries I know; it deserves extensive cultivation. British Queen with me has the crown and shall wear it. Elton Pine I am still gathering (7th September). Through the season they have been in succession in the order named; finer fruit I could not desire, and the crop everything that could be expected considering the season. The soil is a strong retentive loam resting on a clay subsoil.

One of the best Strawberries for preserving is the Roseberry. It is seldom seen now. We do not hesitate to preserve any kind, but take them as they ripen, but I prefer Sir Joseph Paxton and Reeves' Eclipse. They are firm useful kinds, good for market purposes, bearing carrying well.—FRAGARIA.

CHESHUNT HYBRID ROSE.

I HAVE just seen in a letter from the Rev. C. P. Peach that the writer has doubts as to the merits of the Rose referred to above. I ask permission to reply, chiefly that I may have an opportunity of expressing the sincere and universal regret which Mr. Peach's illness and absence have caused to the floral brotherhood, together with our heartfelt hope that we may welcome him next season in our gardens and at our festivals; and to state, secondly, that had he seen the Cheshunt Hybrid as it has bloomed and is still blooming in my rosery, he would agree in pronouncing it one of the most beautiful and bountiful of Roses.—S. REYNOLDS HOLE.

LILIUM AURATUM CULTURE.

MR. WOOD, Sir Erskine Perry's gardener, has four plants, single bulbs, in 8-inch pots, and about 140 blooms on the four spikes, and magnificent blooms they are. The best plant has forty-two blooms on the stem, and with the pot is 10 feet 6 inches high.

Mr. Wood's mode of culture is to pot the plants as soon as they cease blooming, shaking them clean out of the old soil and potting them in loam, leaf soil, peat, and road sidings, chiefly sand that is washed off the roads, in equal parts of each: if more of any of the ingredients is used it is peat. The bulbs are potted very low—more than half way down the pot. The soil is then placed over them to the top of the pot. They are then plunged on the north side of a wall, and sheltered from rains or snow by light screens such as pea sticks or anything not perfectly watertight, and there they remain until the growth appears through the soil, when they are removed to a cold house. When fairly in growth strong liquid manure is used every day until the blooms expand. As this is the period for repotting, a record of Mr. Wood's successful practice may be useful to other cultivators of this fine Liliium.—W. MOWERAY.

I ENCLOSE you a photograph of a Liliium auratum of, to me, an unusual kind which bloomed about a month ago. There were seventy-three blooms all out at once upon a single stem; the cluster of flowers forming almost a cube 14 inches each way, but the blooms were mainly on two sides—back to back—and at the top. The stem was 4 feet 10 inches in length. At the bottom it was about an inch wide and half an inch thick. At the top, where the blooms were, it was 3 inches wide and about one-sixteenth of an inch in thickness. I enclose two sections of the stem, the smaller one being taken 27 inches from the bottom, and the wider one 48 inches from the bottom. The blooms were from 4 to 5 inches in diameter, beautifully formed and nicely marked. The photograph will not give you any idea of the beauty of the blooms, as they were falling

before the plant was taken to the photographer, but it will give you an idea of the plant. Every bloom would have been perfect, but there was not room for all of them to expand fully. I obtained the bulb from Mr. Granger, florist, Ashton-under-Lyne, last spring, and I understand that he has grown similar plants for three or four years, but I have not heard of them elsewhere, and I have searched your volumes for four or five years without finding any allusion to them.—W. M., *Thorncliffe, Dukinfield.*

[The stem of the Liliium is fasciated, and the flowers are on each side of the stem thus flattened. We never saw before an instance in the Liliium, but it is of frequent occurrence in other plants, especially Asparagus.—Eds.]

HEREFORDSHIRE CIDER FRUITS.

I THINK it would be a subject of great interest to those who like myself add to their other hobbies some knowledge of the best cider and perry, as well as dessert and culinary fruits, and at the same time prove of no small advantage to the public as bearing on the successful manufacture (at present a comparative failure) of a national beverage, if our brother pomologists would avail themselves of the opportunity our Journal is now bringing prominently forward, of comparing notes on the leading varieties, not only those now flourishing in the heyday of their maturity and fecundity, but, scarcely less interesting study, those gradually subsiding, slowly but surely, into obscurity and decay.

May I give you a practical illustration of my object? I would venture to ask of your readers for a description and perhaps afterwards for a sample of one of the most celebrated—if not the cider Apple *par excellence* of Devonshire, the Royal Wilding. So celebrated was this Apple at least some 150 years ago that an old writer of that period states, "No less than 200,000 grafts of that variety were propagated in Devonshire and the neighbouring counties in ten to fifteen years."

Now, the Royal Wilding is stated by Batty Langley, the author I have just quoted, to have been raised in Devonshire, and gives a plate and description of the Apple, which if correct does not at all tally in size or shape with the Royal Wilding of Herefordshire (an Apple I may mention *en passant* we never dream of making into good cider, except in combination with other fruits); indeed so marked is the difference, that until I am in a position to draw a comparison I must go so far as to question their being the same variety.—THE HEREFORDSHIRE INCUMBENT.

[We should be glad if some Devonshire correspondent would send us specimens of Royal Wilding to this office.—Eds. J. or H.]

NOTES FROM CORNISH GARDENS.

LAMORRAN—*Supplementary.*

EVERYTHING in the garden at Lamorran bears the stamp of originality, affords evidence of an intelligent grasp of the nature and requirements of every tree and plant, and shows that it must be owing to want of thought as much as to want of pains that better general results are not obtained in so many other gardens. Some Grape Vines planted in an orchard house may be usefully turned to as an example of this: with the exception of shortening and thinning of the wood after the leaf falls the growth is suffered to ramble about untrained and almost unchecked; the berries are thinned, but the bunches are left on with what at first sight appears an almost reckless profusion. There they hang so thick as often to touch each other, large clusters colouring and swelling capitably, without a sign of shanking or disease of any kind, excellent bunches of Alicante and some of the best fruit of Lady Downes' Seedling that I have seen this season. Owners of small gardens having little professional assistance would do well to apply this sensible, natural method of Grape-culture in their own practice. To make it quite clear its chief points may thus be set forth: Let the roots have plenty of rich soil. Encourage every shoot to grow as long and strong as it will. Avoid pinching and nipping off any of the growth excepting when it becomes much crowded, then thin slightly. Give copious supplies of water and air—plenty of air night and day when the weather is warm and genial—closing your ventilators only to exclude cold or high wind. Prune away weakly growth and thin-out and shorten strong growth in winter, but do not prune to a single eye, rather leave 6 or 8 inches of stout young wood with two or three plump buds, and you will have healthy Vines

and plenty of Grapes. This summary of cultural points is probably not exactly a correct statement of Mr. Boscawen's practice, but it is just what experience prompts me to jot down here as a serviceable and timely hint.

Among the Vines in the orchard house were some Roses, just a few choice Teas, which afford quantities of perfect flowers earlier and later than they are to be had in the open air. They are planted at intervals along the sides, and the growth of some trained up under the roof, while others are left with the growth untrained to form bushes. Both plans are good in their way, but when space is an object it is better to turn the roof to account and to reserve the space beneath for other things. Here the space is fully taken up by a fine batch of *Amaryllis*, all seedlings raised by Mr. Boscawen from careful crossings, just bursting into flower full of promise. Lilies, too, were blooming in pots for seed, each flower being experimentally impregnated with pollen brought from flowers of the sturdy plants growing in the open air among the *Rhododendrons*. The *Amaryllises* are never suffered to become dry at the root, nor are the pots laid on their sides, as is often done, but as the growth ceases less water is given, and it is altogether withheld during the period of rest; yet the soil can never become thoroughly dry, as the pots are either plunged or placed upon moist soil. I quite approve of this plan, having successfully followed a similar one in my own practice. The South American stove bulb *Griffinia hyacinthina* was in excellent condition, with numerous other plants not often met with, altogether making the orchard house as remarkable in its way as the other features of the garden. A Bamboo, for many years a flourishing plant upon the open slopes, had seeded and died, like so many others in the south and in Ireland. This is much to be regretted, as it is equally striking and ornamental. *Phormium tenax* from its flourishing condition is evidently perfectly at home here, and the Pampas Grass is something wonderful; so large are the clumps of it, and so strong is the growth, that it produces an effect as bold and prominent as the largest shrubs.

The Cornish Gilliflower, which originated in this neighbourhood, was well represented by a tree of it growing among other Apples, and which was remarkable for its free clean growth heavily laden with fruit and the handsome form of the tree itself. It is much valued as a winter dessert fruit.

In the kitchen garden my attention was drawn to a peculiar sort of *Asparagus* which never seeds, but is viviparous, producing numerous young plants upon its branches. Its origin is somewhat doubtful. It has been here under culture for some twenty years, and is considered infinitely superior to the ordinary sort, being much earlier and yielding large shoots abundantly.—EDWARD LUCKHURST.

DESTROYING WEEDS ON GRAVEL WALKS.

Soak them with carbolic acid about the strength of one of acid to forty parts of water. I have found it successful, but the process must be repeated at least once a year.—E. C. B., *Holton Park*.

AUTUMNAL ROSE SHOWS.

THE county of Sussex is rapidly becoming a great Rose-showing county. It hardly equals, perhaps, at present, Kent and Surrey, its more metropolitan and city-bred sisters, although it owns the great London-super-Mare. Still Rose shows are certainly extending, and large Rose-growers being multiplied. The Horsham Rose Association, started this summer, made an excellent start, and can already boast of a lengthened list of members. During the last fortnight Roses have been shown of high quality both at West Grinstead and also at Horsham.

Sussex does not keep all its good things to itself. At most of the shows there are prizes offered to all England. The West Grinstead Show, held in the park of Sir Walter Burrell, was of large extent, taking in almost all autumnal produce. Though a perfectly baronial hospitality, it was also made the occasion of a great county gathering. Very excellent Roses were exhibited by Mr. Graveley, Captain Carter, Mr. Martin, and others. The all-England prizes for twelve being taken by Mr. Martin, and another who, as Mr. Camm would say, shall be nameless. The show of Roses in the beautiful grounds of Horsham Park on September 6th would not have disgraced July. Many of the boxes would have taken prizes anywhere. Mr. Martin was again largely successful. Castellane was shown

in great beauty, as also Belle Lyonnaise, one of the very best seedlings of Gloire de Dijon, also Malmaison, Dr. André, and E. Y. Teas, which is rapidly ranking as a first-class Rose. There was here a twenty-four as well as a twelve all-England class, besides various county ones, the prizetakers being Mr. Martin first in both; Sir W. Burrell, and Mr. Davis, second and third for the twenty-four. There was also a large and fine fruit, and vegetable, and other flower exhibition.—A. C.

THE WEATHER.

FROM recent reports in the Journal I see that the Potato disease is becoming general throughout England. So far as I know it is not begun in our district yet, but yesterday morning we were visited with something of a different character, which, to say the least, made a more rapid change in the appearance of Potato fields than the disease would do. What I refer to was a severe frost. After a few hours' sunshine whole fields of Potatoes had a quite black appearance. This must seriously injure the crop, as, owing to the long period of dark rainy weather we have had, the tubers are in many cases not more than half-grown. Some of the more tender occupants of the flower garden, such as Dahlias, *Nasturtiums*, *Perilla*, &c., have suffered considerably from the frost. I do not remember a worse season for autumn flowers. The rainy summer has made them late, and now the frost threatens their destruction when they are but coming to their best, and in some cases not even that.—J. HARDIE, *Logie Mar, Aberdeenshire*.

NOTES ON VILLA AND SUBURBAN GARDENING.

THE harvesting of such fruit as our gardens possess and several of our kitchen garden crops must now for a time receive our immediate attention. Let all fruit be carefully hand-picked and carried to the fruit-room or other place for storing them, and any bruised, cracked, or damaged by the attacks of an insect should be put on one side for immediate use. A great number of our Apples are attacked by the Apple weevil, which bores down through the centre of the fruit and out on one side, which causes them to ripen prematurely, and subsequently to drop off. That delicious-flavoured Pear Williams' Bon Chrétien should be gathered before it turns yellow, otherwise it speedily decays. By going over the trees at different periods and gathering a third of the crop at a time, we have been able to supply the table daily (in former years), for several weeks. These same remarks will apply to early Apples that soon deteriorate in flavour after they are once ripe. Our Pear and Peach crops are very slight indeed, but of Apples we have on several trees a very fair sprinkling. On King of the Pippins, Lord Suffield, Beauty of Kent, Cellini, and Wellington we have an average crop, while Cox's Orange Pippin and several others have just a few. Peaches, Nectarines, and other trees trained on walls will require to be kept tolerably thin and free of breastwood, in order to facilitate the ripening of the shoots before the dark dull days of winter are upon us. Keep down weeds in Strawberry beds by running the hoe through them, and clear-off any runners which may from time to time appear. The newly-planted beds are doing well, but when the stock is limited plants may be put in still.

In the flower garden there will be very little change in the operations of keeping all neat and tidy. There is as yet in the neighbourhood of London no perceptible falling-off in the gayness of the beds. Geraniums are with us still in great beauty, and the carpet bedding wherever we have seen it is just at its best, while the herbaceous borders are gay with *Tritomas*, *Pentstemons*, *Phloxes*, and *Gladioli*. The flower stems of *Gladioli* and other herbaceous plants should be cut off as they begin to decay. Cuttings of various bedding plants may yet be struck, full directions of which have been given in previous calendars. Roses are still blooming well; we do not remember having had such a successional supply before, and unless we have some very bad weather we are likely to have good blooms for some time to come. Look to those that were budded in the early season, and if any failures it is not too late to bud again; others will require the binding material removed, otherwise it may cut into the wood. Cuttings taken-off now will strike freely if inserted in a shady border in the open ground. Prepare the cuttings in lengths from 3 to 4 inches, and insert them in rows, making the soil firm around them.

Spring sown Onions ought now to be fully ripe and to be taken up and exposed to the sun as much as possible, for it is impossible to dry Onions too much. If a dry and airy place under cover can be spared so much the better; if not, frequently turning them on mats will cause them to become hard and plump. The ground where the Onions have been lifted will be suitable for planting-out the supply of spring Cabbage, which is in all cases a most important crop. The ground should be liberally manured and deeply dug before the Cabbages are

planted. Twenty inches apart is a very good distance for a permanent crop, but where ground is scarce and small greens are wanted in the spring, they may be planted 1 foot apart, and the same distance between the rows. If this be done, every other row and every other plant must be removed for use as wanted in the spring. Carrots, more especially the Early Horn and James's Intermediate, will require harvesting—laying them in layers of sand in the store-room. Overhaul all Potatoes recently lifted, and remove all decaying tubers. Continue to transplant Coleworts, Lettuces, and Endive from the July sowings, and make another sowing of the Bath or Brown Cos Lettuce; they may be useful for standing over the winter. All herbs should be collected and dried at once. Winter Spinach and Turnips should be sufficiently thinned before they become drawn. A judicious thinning enables them to withstand the severity of the winter better than when they have been left and become drawn.

Chrysanthemums are now growing fast, their pots have become full of roots, and now is the time to help them with manure water. They are very gross feeders; still we advise it to be given them tolerably weak at first. About an ounce of guano in a gallon of water makes a very suitable stimulant for them, or the ordinary mixture of animal droppings diluted will help them. Their bloom buds are now becoming conspicuous, and in order to insure large blooms they must be disbudded, preserving the centre flower buds of the large-flowering and Japanese sections; but for the Pompons we do not advise disbudding at all. The various modes of training for specimens must be daily attended to, and all must be made secure to stakes, or the winds may snap that which it has taken weeks to grow.

Stage and fancy Pelargoniums that have been previously cut down and are breaking freely, should be shaken-out and re-potted into smaller pots. Place them in a cold frame; they will soon emit roots and grow away freely. Zonals that were potted-on in the spring and placed out of doors for autumn display should now be returned to a frame or some place under cover, using the lights only to throw off rains; they will show flower and be useful for some time to come. Primulas and Cinerarias will require timely potting to prevent them from becoming pot-bound.

The stock of Dutch bulbs may now be purchased. Pot those varieties that naturally bloom early first. After potting place them under a cover of a few inches of cocoa-nut fibre or coal ashes, where they must remain for a few weeks to take root without exciting top growth.

All houses will require a complete overhaul in the way of cleaning and painting to get them ready to replace, as soon as bad weather sets in, the stock of hardwooded plants now out of doors hardening-off.—J. W. MOORMAN.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

KITCHEN GARDEN.

This department is sometimes neglected at this time of the year. Many of the quarters are half cleared of the various crops, some of them entirely. In either case it is well to see that no trimmings of vegetables or other refuse are left in the way. Let the ground be cleared and levelled at once, and if a whole quarter is empty it is the best plan to dig or trench it at once. We are picking quantities of Scarlet Runners and Dwarf Kidney Beans. Of the latter the Negro Longpod seems to be the best for a general crop, although for the earliest Newington Wonder bears abundantly, but the pods are very small. We have tried different varieties of the tall Runner Beans, but taking everything into consideration there is no doubt that the variety termed Painted Lady has not yet been superseded. Onions have been sown in drills, and also Cauliflower, in our dry soil. That sown about the 21st of August is apt to button, especially if they are planted out in the hand-lights; whereas a neighbour who does not use hand-lights, but puts out his plants in a dry sheltered part of his garden, finds the 21st of August the best date. If the plants are likely to grow too vigorous before the winter he lifts them a second time and transplants, but the plants are not put out in the open quarter until the early spring months. We have also sown a quantity of Hicks' Hardy White Cos Lettuce; it is an excellent variety of the Paris White Cos type, and has not yet failed to stand over the winter months without any protection. We have earthed-up Celery. It is needless to say that this work must be done very carefully and only when the leaves and soil are dry; it is therefore necessary to take the earliest opportunity of fine weather to attend to this work. See that the soil does not fall into the centre of the plants: to avoid this it is always best to tie the leaves tightly together. Cardoons have now made considerable growth, and must also be blanched in the same way as Celery. A good old-fashioned plan is to tie the leaves together with haybands, and then place the earth round the leaves in the manner of a Celery trench. If they are earthed-up now they will be fit for use about November and onwards. Some persons consider that the best way to blanch

Cardoons is to tie the leaves together and then tie some straw round the plants, or place the straw in an upright position on each side of the row, fastening it at the top. This certainly throws the water from the centre of the plants. Cauliflower plants put out in July will now be forming heads. They ought to have been earthed-up and also kept free from weeds. If this is not done see to it at once. See that gravel walks are kept free from weeds by hand-picking. This is the best way to clean walks, and after going over them a birchbroom should be used to level the path and clear off any withered leaves and dirt.

MUSHROOM HOUSE.

At this season in many districts almost any quantity of excellent Mushrooms can be gathered on the old pasture ground, and a succession may be obtained for some time yet. The Fairy-ring Fungus (*Agaricus oreades*) is very abundant with us, but no one seems to use them in any way, which is a misfortune, as they make excellent catsup, and can be cooked in the same way as the *Agaricus campestris*. Preparation must also be made at this time for the formation of a bed in the house, or if material is ready a bed may be made up at once. The usual way is to get stable manure with a portion of the long straw shaken out of it. The manure must be placed in a heap to ferment; but if it is likely to heat with great violence it may be spread out thinly, which will arrest the fermentation to a considerable extent, and the manure will also throw off superfluous moisture after being turned over every day for four or five days. It may be again thrown up into a larger heap or ridge, taking care that it is frequently turned to prevent over-heating. The method of making up the beds has been frequently described. It will be well for the gardener to be very attentive to the various details of the work, and, what is of very great importance, he must see that at no time is the manure over-heated. The first bed may be made up on the ground, to be followed by others raised on shelves one above another as high as the walls of the house. The manure must be beat down rather firmly; an ordinary brick wielded in the hand is good for this purpose. For those who do not possess the advantage of a forcing house for Mushrooms it has been recommended to obtain a supply by growing them in boxes to be placed in a cellar or some similar place. A writer in the Transactions of the Caledonian Horticultural Society more than fifty years ago procured boxes 3 feet long, 1½ foot wide, and 7 inches in depth. He spawned the manure, which was rammed into the boxes in the usual way, and each box produced from twenty-four to forty-eight pints of button Mushrooms. The writer further adds, "I have lately found it very useful to add to every three barrowloads of horse dung one of perfectly dry cow dung, beaten down to powder, as it were, and well mixed amongst the horse dung after it has lain under cover four or five days to dry." This plan of mixing the dry cow manure with that from the stable we know to be a good one, but it ought to be gathered in the summer and be dried in the sun. Gardeners know how difficult it is to get the manure for their Mushroom beds sufficiently dry, and when this is the case they would find how useful two or three cartloads of this sun-dried material would become. Artificial heat in the Mushroom house ought to be avoided as long as the night temperature ranges about 55°; a high night temperature is not conducive to the quality of Mushrooms. Two things must be guarded against in the growth of Mushrooms, and that is over-heating the beds and too much moisture in the manure.

VINERIES.

If a gardener were asked the question whether it was most difficult to grow Grapes to perfection or to preserve them after they are ripe, probably he would be puzzled to say. In our district, which is within the radius of the thick clammy London fogs, it is almost impossible to keep the berries from moulding or from injury in some way; already one or two berries have become mouldy. It is quite necessary to watch frequently for traces of decay on the berries, and to have them removed before they do injury to the others. For want of this precaution a mass of berries are destroyed together and the appearance of the bunch is ruined. As this is the season when most attention is required the cultivator must be on the alert. A judicious use of the heating apparatus and careful ventilation is necessary to success. Many vineries are not provided with the means of ventilation in wet weather at the apex of the roof, and in wet weather many persons put on the heat to dry the atmosphere. This it might do if there was a good circulation of air through the house. We rather prefer to do without heat in such weather, and to ventilate freely and dry the atmosphere in clear weather.

Preparations as to cleaning the walls and woodwork of the houses, also removing the loose bark and washing the Vines, have been carried on with us during the past week. The walls have been well washed with limewash, and the Vines will also be washed with strong soapy water before painting the canes with a mixture of soapy water, a small portion of soot, and sufficient sulphur to thicken the mixture to the consistency of thin paint.

PLANT STOVE AND ORCHID HOUSES.

Allusion has already been made to the necessity of carefully

looking over all bug-infested plants and utterly destroying the pest. The first cleansing must be followed up by another in three or four days, and yet another and another at short intervals. A year or two ago when inspecting a celebrated private collection of stove plants I remarked on the absence of bug, and the gardener stated that he had none on the place. He said that a plant sent in from the nursery, though apparently clean, soon developed a colony of the pest, but he had it looked over every day for the space of two or three weeks, after which it was pronounced to be clean. It is not possible to grow many of our best stove plants satisfactorily, such as *Ixoras*, *Dipladenias*, *Stephanotis*, &c., if they are not free from this pest; the insect gets into the flower trusses and makes a sad mess of them. Red spider is easily destroyed if the leaves can be washed clean with soapy water and the plant be syringed daily afterwards. A most difficult intruder to overcome in the plant stove is the lively little thrips. Besides moving about at a rapid rate they get into the heart of many tender-foliaged Orchids and other plants, where you can neither handwash nor syringe them. Fumigating the house with good tobacco is the best way to destroy them, but it must be done with great caution, as many Orchids, Ferns, and tender plants suffer from too much tobacco smoke. It took us nearly two years to clear the stove of this pest, and it was done by fumigating in the late autumn and winter months. Whole collections of Orchids are depreciated in value to an alarming extent by the depredations of this pest. It is particularly fond of the tender leaves of some varieties of *Cypripedium*, especially *C. superbium* (Veitchii). It will now almost be possible to do without using the shading material. If it is necessary to use it at all it may only be done when the sun shines directly on the plants.—J. DOUGLAS.

TRADE CATALOGUES RECEIVED.

Hooper & Co., Covent Garden Market, London.—*Autumn Catalogue of Bulbs, &c.*
William Rollison & Sons, The Nurseries, Tooting, London.—*Catalogue of Cape, Dutch, and other Bulbs, Fruit Trees, &c.*
Dick Radclyffe & Co., 129, High Holborn.—*Catalogue of Dutch Flower Roots, Trees, Garden Requisites, &c.*
Thomas S. Ware, Hale Farm Nurseries, Tottenham, London.—*Autumn Catalogue of Bulbs, Tuberous-rooted Plants, &c.*
Stephen Brown, Weston-super-Mare, Somerset.—*Autumn Catalogue of Bulbs and Flower Roots.*
Samuel Yates, Old Millgate, Manchester.—*Illustrated Catalogue of Flower Roots.*
W. Tait & Co., Capel Street, Dublin.—*Catalogue of Superior Dutch Bulbs, &c.*
F. Brassac, Florist, Faubourg Bonnefoy, Toulouse.—*Special Catalogue.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

BOOKS (S. D. T.).—Keane's "Indoor Gardening." You can have it free by post if you enclose twenty postage stamps with your address.

TREATMENT OF CARNATIONS AND PICOTEES (*A Lover of Flowers*).—To grow them satisfactorily the plants must be wintered in cold frames, and be planted out in beds in March, or potted into large pots in which to bloom. The most hardy sorts will live over the winter in borders, but even of them many die during the winter months.

AZALEA LEAVES INJURED (*An Old Reader*).—There is no trace of thrips on the Azalea leaves sent, but there is of red spider. This pest is very destructive. You must syringe the plants freely when growing, which will keep it in check.

MENTHA PULEGIUM HARDY (*A Constant Subscriber*).—It is a native of England and the south of Ireland, and is quite hardy.

DIGGING-IN VETCHES (*E. A.*).—Sow as much seed as if the crop was to be mown.

PELARGONIUMS (*J. E. W.*).—You do not state where they are to be grown. Go to any florist and select for yourself. No seedling Pansies have arrived.

MANURE (*N. J. M.*).—The stable manure worked through the pigstye is the most fertilising. We should apply it to each crop at the time of planting, and in a thoroughly decomposed state.

NOTICE TO LEAVE (*Novice*).—If your wages were paid weekly your master need not give you more than a week's notice.

APPLES (*G. S.*).—Any of the large nurserymen who specially cultivate fruit trees can supply all the varieties you name.

LEAVES AS MANURE (*Sambo*).—They are beneficial, and your inserting them when fresh is an economical mode.

MUSHROOMS (*Franklin*).—Your Fungus is one of the numerous varieties of the common Mushroom which approach the Horse Mushroom in character. We have, however, never before observed any variety change colour on breaking to the peculiar dead and somewhat dark brown colour of your specimen.

IMPROVING SOIL (*Rose*).—Your sandy soil can only have its staple improved by adding large quantities of clay, chalk, and bricklayers' rubbish.

CLEMATIS (*C. S.*).—*Clematis florida* flore-pleno.

CITRON LEAVES BLOTCHED (*L. L.*).—The blotches are caused by deficient root-action and too much shade. A little weak manure water and more light will prevent the blotching. Those out of doors now were injured probably before being moved from the house.

GRAPES CRACKING (*M. R. P.*).—The Muscat Hamburgh is especially liable to crack its berries. The Vine supplies sap faster than the skins of the berries can expand. There is probably an excess of moisture about the roots.

SCALE ON VINE LEAVES (*John Sharp*).—We do not know the cause of plants being infested with insects other than that the plants upon which they are found afford the elements of their existence. The insect infesting the leaf sent is the Vine scale (*Coccus vitis*), and the black mould or fungus upon the surface of the leaf is the result of the insect's excretion. It may be destroyed by a solution of soft soap—half a pound to half a gallon of water, adding a wineglassful of spirits of turpentine, thoroughly mixed, and applied to the parts infested with a brush, syringing the parts dressed with the compound before it become dried upon the leaves. In winter, when the leaves are off and the Vines pruned, the Vine stems should be freed of the loose bark and be dressed with the compound in every part, brushing it well into every angle and crevice of the bark.

CLEMATIS AND WISTARIA PROPAGATION (*Rosery*).—Layering is the most certain mode of propagating the Wistaria, but cuttings of the strong roots may be taken in autumn and inserted in sandy soil, or cuttings of the young shoots when getting firm inserted in sandy soil in a sheltered situation under a hand-light. We should layer a long ripened young shoot in autumn, covering the shoot with about an inch of soil, the whole extent of the shoot to be laid in the soil, and almost every bud will form a plant. Clematis may be layered in the same way, or cuttings put in of the young shoots after they become firm under a hand-light in sandy soil. A more general mode of propagation is by grafting upon the thick roots of the hardier kinds, as *C. vitalba*, using scions of the ripened shoots, operating in early spring under glass.

APPORTIONING GLASS STRUCTURE (*H. P.*).—Your 90 feet length of house we should divide into 20 feet for early vinery, 24 feet late vinery, 20 feet for plant house, and 26 feet for fruit house, which we presume will be an orchard house. As to arrangement, we should have the plant house at one end and next the boiler, taking the pipes through it in a flue with an open iron grating, then the early vinery and the late vinery, following with the fruit house at the other end, the pipes being conveyed through the vinerias as well as the plant house in an open iron grating-covered flue, having the required piping taken from the main flow up the houses. We should have the border for the Vines the whole extent of the house inside, and though the Vines would be planted inside have part border outside, the side walls being arched so as to allow of the Vine roots passing from the inside to the outside border. For the early house we should have Mill Hill Hamburgh, Black Hamburgh, White Frontignan, Buckland Sweetwater, and Foster's Seedling; or if you wish more black than white Grapes have two Black Hamburgh and omit a white kind. For the late house two Muscat of Alexandria, Black Alicante, Lady Downe's, Mrs. Pince, and Gros Guillaume.

RENOVATING OLD GRAPE VINES (*H.*).—The only fault you find with your old Vines is weakness of growth and smallness of fruit; the border is therefore sound and well drained, or you would have complained of shanking. Why, then, should you renew it and incur a considerable expense when more simple measures will meet your requirements? Give the entire border a surface dressing 8 inches deep of three parts old and very rich manure with one part chopped turf or road scrapings; avoid close pruning, rather leave on 6 inches of young wood at each spur with a plump eye near the end, and take up a young rod from some point near the bottom of the rafters with a view to the removal of the old one in a year or two's time, the strength of the young growth being your guide. We do not like turning out Vines into the open air in winter. In your case it appears to be unavoidable, yet there is no reason why they should not be protected from cold by mats and litter, provided they are not left uncovered too late in spring.

LEYCESTERIA FORMOSA (*E. C. O.*).—The name of the shrub is *Leycesteria formosa*, a native of Nepal. It is hardy, but sometimes suffers from very severe frost at this season of the year. It is propagated by cuttings of the matured growth inserted in a cold frame or under a hand-glass. It also comes readily from seed in spring and from cuttings of the young growth. Any nurseryman will supply you with it at 1s. a plant or 6s. a dozen. There are pods of ripe seeds upon the flower cluster which you sent us.

CUTTING-BACK FANCY PELARGONIUMS (*Amateur*).—Fancy Pelargoniums should be cut back immediately after the flowers fade and be put out in the open air fully exposed to the sun. When the buds of a new growth begin to swell shake all the old soil from the roots, shorten them, and then repot, still keeping the plants in the open air till the new growth is growing strongly.

GROWING FINE CARNATION FLOWERS (*Idem*).—To have large flowers and uniform in size cut off all the little buds, retaining only a few of the most promising. This plan has to be followed in the production of most other flowers, and also of fruit; hence the frequent disappointment of those who, seeing fine specimens at shows, purchase plants in the expectation that every flower will be equal to those in a prize stand.

DETAILS OF A SPAN-ROOFED VINERY (*W. Pemberton*).—Let the house stand lengthwise north and south, then the morning sun will shine upon the eastern slope and side; at mid-day it will warm the entire roof, and so pass round to the west later in the day. You can grow Grapes and Roses perfectly well in such a building. Make two arches in the side walls, the tops being 6 inches below the surface; then plant inside the house and close to the east wall three Vines, making for them a border 2 feet wide inside the house to plant in, and let the roots pass through the soil in the archways into an outer border. Plant two Roses in the same way close to the west side, and train the growth upwards till it meets the Vines. Put a stage for plants in the centre with a path all round it, and let your brick flue be under the stage, passing along and returning under the path at any suitable point. Order strong Vines now, and have them put aside with your name fastened upon them at the nursery, but do not plant till the end of March, or rather just as the buds begin swelling; then shake all the soil off the roots, uncoil, and spread them carefully out to their full length in the border, covering with 6 inches of soil. If the sap is in motion when you receive the Vines do not shorten them but rub off the top buds, so that the new growth starts from the bottom of the roof-slope. You will thus avoid loss of strength from the bleeding which so often follows late pruning. Give no check to a single shoot of the first year's growth.

COMBINED VINERY AND PLANT HOUSE (*C. T. J. M.*).—For a late vinery the Vines may be planted outside; but this is not the best plan, entire crops of fruit being frequently spoilt in autumn by heavy rain saturating the border

and causing such a strong flow of sap as to make the fruit crack and decay. Provision ought always to be made to throw off the rain from such a border after the fruit is ripe. Do this and you may plant outside with advantage. If you do turn the vines outside during winter protect them from severe frost with litter and mats, but if you only wish to use theinery as a greenhouse in winter why disturb the vines? The temperature of a greenhouse would not excite premature growth. Alicante and Lady Downe's Seedling are the best late-keeping Grapes, but you must keep out plants till the fruit is used, or much of it will be spoilt by the moisture arising from them. It would facilitate watering and improve its appearance if the stage did not go quite to the end farthest from the earlyinery, but had its shelves continued along to the back with a path at both ends. The heating pipes could easily be connected with those in the earlyinery and put along the front as you propose. Let the valve be in the early house to prevent waste of heat. A 4-inch flow-and-return pipe would no doubt keep out frost in a small house, but we cannot tell how much piping will be required without knowing the dimensions of the house and the maximum winter temperature.

FIG CULTURE (*C. T. J. M.*).—Plant against a south or south-west wall in soil that is not more than 15 inches deep, making the bottom hard with concrete or stone rammed down hard to keep the roots from going down. Fasten the leading shoots to the wall, remove all suckers, and nip off the spring shoots at the third or fourth leaf to induce a second growth of three or four lateral shoots, every one of which should have some incipient fruit at the base of the leaves near the tips. Protect the entire trees with mats or litter during winter, for if the shoots are exposed to severe frost not only will the crop be lost but there will be a risk of the shoots being also destroyed. If the growth prove weakly and the fruit small apply surface-dressings of rich manure, and thus draw the roots to the surface and feed them as much as you please. When the fruit is half grown frequent doses of sowage or guano water poured over the roots tend to increase the fruit's size and flavour. Never let the trees suffer from drought, or the fruit will turn yellow and fall prematurely. Brown Turkey is the best sort for your purpose. It is hardy and a sure and abundant cropper. If you require large fruit plant Brunswick, and for a white sort choose White Marseilles.

SLUG FROM GARDEN (*William Gorrie*).—The slugs sent by you are not unfrequent in the villa gardens in York Road, Trinity, Edinburgh; and as fully as bad plant-destroyers as the several common kinds (from all of which they differ in having a prominent ridge or keel along their backs) is *Limax Sowerbii* of Ferrussac (Forbes & Hanley, Brit. Mollusca. iv. pl. 333, fig. 3.—*L. carinatus*, Gray), common near London but rarer northwards.—I. O. W.

NAMES OF FRUITS (*Grig*).—Dumelow's Seedling. (*Knutsford*).—1, Keswick Codlin. The others not known.

NAMES OF PLANTS (*X. A. M.*).—*Lastrea dilatata*. (*J. Shearer*).—1, *Campylopus rotundifolius*; 2, *Achillea Ptarmica*; 3, *Polygonum Persicaria*; 4, *P. aciculare*. (*G. O. S.*).—1, *Acanthus mollis*; 2, *Physalis Alkekengi*; 3, *Gallieria aristata*. (*Mrs. Pettit*).—The Lady's Tresses (*Spiranthes autumnalis*). (*Mac*).—*Cystopteris fragilis*.

POULTRY, BEE, AND PIGEON CHRONICLE.

COMMITTEEMEN EXHIBITING.

A CORRESPONDENT in a contemporary considers himself a sufferer because at some show where he has exhibited a committeeman won the prize which perhaps would otherwise have been his. He urges that the managers of shows should not exhibit: in fact, he wishes himself to enjoy the fruits and pleasure of exhibiting while others may do all the work. The reply of the editor is very good; he says, "It is quite certain that if committeemen were debarred many shows would never be held, as the keen personal interest in the subject is the chief spur to exertion." This certainly all should readily see, and without doubt once such a plan as this correspondent urges was carried into effect immediately exhibitions would on all sides come to a full stop. Those that remained would be merely speculative exhibitions in every way, got up in some favourite place of resort as a popular amusement, or as a means to get people together; for there are indeed but few fanciers who can give time and money to get up a show, and then not even have the privilege of seeing their own birds compete for the prizes. And the speculative exhibitions, they would in their turn probably cease, for a bad year might come, or a wet day, and the receipts not being sufficient the prizes would very possibly not be paid, and the show would collapse. This has already happened frequently, and without doubt the genuine exhibitions, such as withstand a bad year and still bloom forth in another, are those got up by real fanciers—lovers of poultry in every sense of the word, who promote the show for their own pleasure and to see their birds side by side with their neighbours and friends.

We also agree in thinking the line may, however, possibly be drawn with the secretary, as he naturally has often to be thrown with the judges all the while the awards are being made; but this is less difficult to overcome, for the secretary can be a paid one, such as many exhibitions now have, though, of course, the more ardent a poultry fancier a man may be the more suitable and energetic secretary will he make; and as it would be hard to cut out such a man from the chance of ever exhibiting at his own show, and the fact of the secretary exhibiting was really objected to, it might possibly be arranged for some members of the committee to take in turn these arduous duties which some one must perform. The editor of our contemporary, however, rightly admits that at some shows with some judges the fact of the committeemen themselves exhibiting and carrying off the chief prizes is open to much comment. And this once more opens up the case of how very important it is for exhibitors to

insist on the names of the judges being published; and for the show-promoters themselves, how important it is for them in their own interests, if they want many entries and the birds of the best exhibitors, to publish invariably this information, for we have many judges whose names are themselves a guarantee that all that is fair and honest will at least be done by them. Such names we need not mention, they are well known; and the fancy knows that no committeeman or secretary would ever be the least benefited by any sly hints or remarks they may make as to the ownership of any individual pens with those gentlemen.

We remember a long controversy in this Journal a few years ago on this subject (it is in vol. xvii.); and though we are far from wanting to open up the subject again, we cannot refrain from saying that those fanciers would be foolish above measure who tried to insist on the committee of a show not exhibiting, supposing they for their part had properly advertised who their judge was to be, for then exhibitors could use their own discretion as to exhibiting or not.—W.

LANGSHAN FOWLS.

I HAD some chickens hatched on the 9th of April, and on the 21st of August the pullets, then only four months and a half old, commenced laying. I have never known Brahmas or other breeds lay under five months, and then very rarely. We may therefore, I think, consider the introduction of the Langshan a great acquisition to all poultry fanciers and breeders. I had one of the cockerels on my table last week, and pronounce the flesh to be very superior, light in colour, and most delicate and nourishing.—H. J. BUCHAN, Southampton.

BATH POULTRY, &c., SHOW.

THIS Exhibition was again an apparent success, for the tents were thronged with people and the weather was fine, while the quality of the exhibits was extremely good. The entries, too, in many classes were heavy. The poultry Judge was the Rev. G. Hodgson. *Dorkings* had four classes, and we were sorry to see so few White Dorkings. The Coloured and Silver-Grey, however, made ample amends. The cup went to a Coloured cockerel, the first in the catalogue; a good bird, but hardly likely to make a very large one. The third had more promise. In Silver-Grey cockerels the winner was capital and well ahead. The pullets, too, of both colours were also good. In *Cochins* the champion cup fell to the Buff cockerel shown by a new Cochinchina exhibitor. He is a well-standing good-coloured bird. The first Buff pullet wanted more foot-feather, or else was of much merit. All the winning White cockerels were good, the first excelling in shape and feather and the second perhaps in colour, while the three White pullets were all extremely good, as, too, was the cup Partridge; in fact the latter was a marvel of pencilling and a large-boned growing bird into the bargain. Dark *Brahma* cockerels were disappointing. The first has no promise of greater size, though now pretty. The third was very square and large, but had hardly enough feathering. All the pullets were pencilled, but we fancy many of them were inclined to be too pale under the throat. Light cockerels were good, the winner the Newbury cockerel, while the first pullet was very large but cloudy and not very straight in hackles. *Hamburgs* made good classes and show promise of sharp competition for the future, but many birds were not yet well up and want more time. We noticed the Judge went in apparently for very bright colour in the Golden-pencils. The first Black cockerel and ditto pullet were very forward and matured. *Game* had all to meet in the same divisions, but the quality considering this was moderately satisfactory. The *Leghorns* had two classes, and the first Whites were very fair. The Browns did not seem so forward or so well matched, and in both varieties we noticed too much yellow in the earlobes. The *Spanish* were fair. A nice cockerel of Mr. Jones's from some mistake got into the wrong class, or he would have run the winner close. The first pullet was pretty and nice in face. The *French* were not up to a high standard. We observed that the Judge did not object to Crève combs in the Houdan cockerels, which caused a little dissatisfaction among the fanciers of the breed. In Crèves the first pullet was larger than the others but a little rusty in colour, while the first cockerel had a very poor comb. *Silkie*s were a pretty little lot, but the cup pullet had green feet and not a very perfect fifth claw. Mrs. Holmes sent a good pen, and so did Messrs. Fowler, but the latter were younger. In the Variety class Black *Polands* of much merit won the prizes. Dr. Lloyd's were well-grown and large-crested birds. The *Bantams* had two classes in the Variety. A good pen of Silver-laced were first and Black *Rosecombs* of good colour second, while *Black-boots* of much merit were third. The Any age classes were conspicuous for the cup pen of *Dorkings* (Burnell), the first Black *Hamburgs*, and the two winning pens of *Game*. The local classes were very good, and the birds would have stood high in the open classes. The cup went to a beautiful White *Cochin* pullet and the first in cockerels to a good Light *Brahma*,

but we confess we thought Mrs. Drummond's bird of the same variety in pen 470 was badly used. He was a beautifully shaped and prettily combed bird and had a great deal of style.

The *Pigeons* were well judged by Mr. Tegetmeier; and Mr. Baker, who brought a good team, worthily secured most of the first prizes; but in Turbits he had to give way to the Early Wood birds, and in the Variety class to Mr. Parsons.

The *Rabbits* were judged by Mr. Allison, and were generally well filled and contained some splendid specimens. Among those specially worthy of notice in the classes for Lops were Mr. J. Cranch's beautiful first-prize doe and a splendid Black Rabbit exhibited by Messrs. Fell. The first and second-prize Tortoiseshells were very fine specimens with little to choose between them, and we should have much admired Mr. Archer's first-prize doe in the Any other colour class were it not for the very peculiar appearance of her eyes, which if not a blemish was at least no beauty. The Silver-Greys proved an excellent class. Messrs. Fell's third-prize Rabbit was even better in general colour than their first-prize specimen, but the darker nose of the former justly put him out of court as compared with the beautifully shaded head of the latter, which also gained the cup. Himalayans were also good. The first-prize Rabbit, though not very large, was unusually dark in all points and neat in shape; the second and third a trifle larger, but not so dark, especially in the feet. In Angoras the judging was evidently by size, since the third-prize specimen as well as No. 950 (Crook) were conspicuous by the fine silky quality of their wool as compared with the coarser coats of the first and second prize-winners. The Belgian Hare class had twelve entries of very unequal merit, and the winners seemed judiciously selected. Dutch were scarcely as well represented as the other classes, but the winners were nice specimens, the first-prize Rabbit neater in marking and brighter in coat than the second. In Any other variety the competition was small, but the prizes fell to Rabbits which seemed well worthy of the selection made in their favour. The local class hardly produced as many entries as might have been anticipated, but the selling class was well filled and contained many excellent bargains, especially in Lops, which doubtless found a ready sale. Altogether we derived great enjoyment from attending what we may fairly regard as one of the best shows we have seen for some time past in the south of England.

THE Bath Show seems to have become an institution, for it has lived and prospered four years. Then it has its big brother, the horticultural, to lean on, so one helps the other. But there must be some alterations, or the attendance, which was not so good as on former years, will fall off still more. On my entrance to the Sydney Gardens I paid 2s. 6d.; second and further entrance to the Poultry Show is, which with the catalogue make actually an outlay of 4s. before a bird can be seen. I would advise that it might be possible to have a separate entrance for the poultry, so that those who are only bird fanciers should be permitted to enter on paying something less than 4s. Then, next, the poultry Judge was overworked. It is not fair to ask any one man to judge upwards of five hundred birds. Then the numbers did not run properly, and the lower tier containing some of the very best birds was too low, and they could not be seen on a dull day. As a summing-up it may be said, that although the entries were not so large, the birds were of a better class. Some of the chickens were magnificent—witness Mrs. Acton Tindal's champion Partridge Cochin pullet, such penciling, &c. But I must pause or I shall be intruding upon "W's" domains, for I saw "W." there looking intent and critical. Away then to the

Pigeons.—There were about two hundred of these, and, of course, remembering the time of the year, many were badly in moult. Carriers were shown in two classes. Cocks and hens of any colour.—The first cock (Baker), a Black of good frame and carriage, a sure winner. Second (Cucksey), also Black, good beak wattle, but thick neck. Third (Baker), a Dun and nice. Hens.—First (Yardley), a Dun in very heavy moult. Second (Baker), a good young Dun. Third a Dun as well. Well done, Duns. Pouters of any colour (cock and hen classes).—First cock, White, a very showy nice bird of Mr. Pratt's. Second (Baker), a Blue and small. Third (Pratt), Blue, with large crop but too thick in girth. Pouter Hens.—First (Baker), a noble Black, she deservedly had cup as well as first. Second (Mrs. Ladd), a fine big hen, but out of show, and not inclined to be showy, perhaps from want of talking to. Third (Baker), a Blue, overgay but very showy. A nice Yellow of Mr. Pratt's was commended. Barbs were no doubt very good, but being shown in pairs was, of course, a trial to fanciers. Out of the twelve pairs more than half were good. The honours went to the three fanciers—Baker, P. H. Jones, and J. Long, in the order of the names. Tumblers, best pairs, not Almonds.—First, Yellow Agates, rather light but good heads, particularly that of the hen; second Red Agates; third a fine pair of Red Agates. I was sorry to see a pair of odd-eyed Balts commended. If a high-class Tumbler has not pearl eyes he to my mind does not

deserve notice. This was a good class, and many Tumblers of all kinds continue to be bred with success. Almonds, few.—The second prize (Yardley), had a very good hen. First and cup (Baker), both excellent birds. Dragons, in pairs.—Fourteen entries.—First Yellows and very good ones; second Blue; third Blue again. No. 622, a highly-commended pair of good Whites. Antwerps, Short-faced and Long, were, particularly the latter, considered by the Judges as of much merit. Owls.—Only four pairs. First a neat pair of Silvers (Harris); second, Whites. Nuns.—A few more than usual. Of course all were Black, none Red or Yellow. Mrs. Holmes, a Bath fancier took second. Dr. Etheredge had a highly commended pair of interesting birds not often seen, Nun-shaped, but the colouring reversed, the head being white, the body black. Turbits.—A capital yellow-shouldered pair of Mr. Cresswell's were first; second a nice Blue (Gregory); third (T. C. Burnell). One pair only of Blacks which had and deserved a commendation. Fantails.—The winners were all Whites. First (Baker), second (Cresswell), the hen the best bird in the class; third (Loversedge). Jacobins.—In this class an unusual occurrence took place, all the prizes going to Yellows, or at least none to Reds. First (Baker), an excellent pair, one particularly. Second a nice long pair Third Whites, and may be improved. No. 633 had a commendation. Trumpeters.—A few of the older style, but of course not noticed, the winners being of the true Russian type. First, Black; second and third (Woodford), good Mottled. No. 691 were Chequers, a colour in Trumpeters which I do not remember having seen before. Then came a class for new or distinct variety, none very new, and the Swallows were the best. Of the Pigeons hatched in 1877 were many promising birds. A good White Pouter first, a very promising good Black Carrier belonging to Mrs. Holmes second. The Selling class had a lot of bargains in it. Dun Carriers, White Owls, and a pair of Archangels may be mentioned. As I fear Bristol shows are no more, so I trust Bath will keep up, but people must not be charged 4s for a peep at it.—WILTSHIRE RECTOR.

POULTRY.—DORRINGS.—Coloured.—Cockerel.—Cup. Rev. H. F. Hamilton. 2, T. Briden. 3 and 4, T. C. Burnell. Pullet.—1 and 3, T. C. Burnell. 2, R. W. Beachey. Any other variety.—Cockerel.—1, T. C. Burnell. 2, Mrs. Laing. 3, T. Moore. Pullet.—1 and 2, T. C. Burnell. 3, T. Moore. *vhc*, R. A. Boissier. COCHINS.—Cinnamon and Buff.—Cockerel.—Cup. E. Burrell. 2, W. Nickolls. 3, Mrs. A. Tindal. Pullet.—1, J. Gee. 2, W. Nickolls. 3, E. Burrell. *vhc*, Rev. C. J. Watson. White.—Cockerel.—1, Rev. R. S. S. Woodgate. 2, Mrs. A. Tindal. 3, J. Long. *vhc*, J. Turner. Pullet.—1, Rev. R. S. S. Woodgate. 2, J. Long. 3, Mrs. A. Tindal. *vhc*, Mrs. Lang. Rev. R. S. S. Woodgate. Any other variety.—Cockerel.—1, Mrs. Gordon. 2, Mrs. A. Tindal. 3, J. K. & R. R. Fowler. Pullet.—Cup and 2, Mrs. A. Tindal. 3, H. C. White. *vhc*, W. Nickolls. R. P. Percival. BRAHMAS.—Dark.—Cockerel.—1, R. A. Baker. 2, E. Lloyd. 3, H. Lingwood. Pullet.—Cup and *vhc*, W. R. Garner. 2, H. Lingwood. 3, T. Earle. Light.—Cockerel.—Cup, P. Haines. 2, H. A. Barclay. 3, G. B. C. Pullet.—1, T. A. Dean. 2, P. Haines. GAME COCKS.—Cup. J. Colgrove. 2, C. W. Laxton. 3, W. Perren. Pullet.—1, J. Colgrove. 2, W. Perren. 3, G. Bell. HAMBURGS.—Gold and Silver-pencilled.—Cockerel.—1, J. Calcutt. 2, H. Pickles. 3, H. K. Hobson. Pullet.—1, H. K. Hobson. 2, O. E. Cresswell. 3, F. C. Davis. Trueman. 2, D. Oldfield. *Extra 2, H. M. Sturt.* 3, C. King. *vhc.* H. Beach, L. Capenhurst, H. E. Clark.

ALTRINCHAM POULTRY, &c., SHOW.

THE annual Show was held at Altrincham on Saturday last. The prizes for poultry were very good, and the classes numerous, and some were well filled while others were but moderately supported.

Turkeys and aquatic birds headed the list, and kept up the high character of this locality. *Spanish* were very good, especially the hens, but of *Game* there were very few, and mostly of indifferent quality or out of condition. *Dorkings* good as to size. In *Cochins* we could not agree with the awards in many cases. In *Buff* cocks a worn-out old bird very mealy and light in colour was placed first, the second in our opinion being far the best, and especially in colour, which was perfect. In hens a pullet, good in shape but pale in colour, was first, a hen second, and a good coloured pullet third. In the other classes the winners were all Partridge, the cocks particularly good. *Light Brahmas* few and only poor; *Dark Brahmas* cocks were well placed and a good lot, but we were puzzled with the awards in hens, first being a well-laced pullet, small and bad in leg and foot feather, by far the best being pen 967 (Henshall), highly commended only. *Hamburgs* as usual good here, the awards being generally well made. *French* fowls were very good in both classes, though in hens they were small and young. *Polish* but three entries of moderate birds. *Bantams* a good section, the *Reds* and *Piles* in *Game* being very good, but those of Any other variety (*Blacks*) were wretched.

Pigeons were a very good entry, and they were well cared for in a tent, and nicely arranged. First on the list were *Carrier* cocks, and these were very good; *Blacks* first and second, and *Dans* third. Hens also very good. In *Pouters* first was a *Blue*, second a *White*, and third a *Yellow* hen, but none in the class were at all in show form. *Barbs* were very good, and these also had two classes, many being capital in skull and eye, but sadly out of feather. *Almond Tumblers* were poor, except the winners; a hen placed first was a perfect coloured bird and well marked. Both the other *Tumbler* classes were good and well filled. In *Blue or Silver Dragons* Mr. Wood carried all before him. In the Any other colour first was a perfect-headed *Blue Chequer*, but rather coarse in beak-wattle; second and third *Yellows*. *English Owls* were a large class, the winners being *Blues*, and good, but most of the others poor, except pen 1197 (Thresh), which should have had a place. In *Foreign Owls* *Whites* won, and in *Jacobins* the winners were all *Reds* in the first class and *Blacks* and a *White* in the next class. There were two classes for *Turbits*. In the first *Blues* carried off the prizes, and in the next a good *Black* was first and another second, and a *Yellow* third. *Antwerps* were good in both classes and well placed, except the first *Blue* in the *Long-faced* class, which was more like a *Rook* than a *Pigeon*.

There were six classes for *Rabbits*, but many of the pens were empty, and as a rule the awards were very curiously made. In *Lops* first was a nice *Blue-and-white*, which we know to measure well, the next best in the class being a self-coloured *Grey*, which for length and quality is even better than the first. Third a *Pawn-and-white*. *Angoras* a good class but badly judged. First a *Rabbit* deep in moult with fur on the sides, a back not longer than a *Silver-Grey*, with just a fringe of long wool as a skirt; the best was awarded third, and was a good one all round. The second best, unnoticed, was pen 1352 (Ridsdale). *Himalayas* a poor lot, the best being selected, except that the third

had a white spot on the nose. *Dutch* a very bad lot. *Silver-Greys* were moderate and fairly chosen. In the *Variety* class first was a poor coloured common *Grey*, second an exquisite *Silver-Cream* which should have been first, and third a poor *Belgian Hare*, but far better than first. Messrs. Gilbert and Pepper's pens were empty.

POULTRY.—**SPANISH.**—*Black.*—*Cock.*—1, J. Leeming. 2, J. Thresh. 3, J. Powell. *Hen.*—1, J. Powell. 2, J. Leeming. 3, J. Thresh. **GAME.**—*Black Red.*—*Cock.*—1, W. Rudd. 2, E. Bull.

JUDGES.—*Poultry:* Mr. R. Teabay, Fulwood, Preston. *Pigeons and Rabbits:* Mr. J. Hawley, Bradford, York.

STAFFORDSHIRE POULTRY SHOW.

THE annual meeting of the Staffordshire Agricultural Society was held at Burton-on-Trent on the 4th and 5th inst. The arrangements were of an elaborate character and well carried out, the local Committee rendering Mr. Tompkinson, the General Secretary, ample assistance. A capital marquee was provided for the poultry, the pens being from Clark of Stoke-on-Trent. The Show was the best of chickens we have seen this season. *Black or Brown Red* cockerels headed the list with good entries, but many of the former were very coarse; in cockerels the awards being made to *Brown Reds*. The first very young, but perfect in shape and colour; second losing by very little except length of body. In pullets two well-moulded *Black Reds* obtained the places of honour, but the first (a gem in other respects) was dark eyed. Several birds highly commended will be better all round when tamed down to the show pen. Any other variety, cockerel and one pullet.—First *Duck-wings*, the best we have seen this season; second *Pile*, also very first-rate. *Spanish* were a superb lot, first going to a pair of birds the pullet in which pen was of marvellous quality of face and drop, reminding us of the celebrated *Queen* of some years ago brought out by the same exhibitor, the only fault in this case being that as yet the comb is perfectly straight, like that of a cock; second an even pair, as also pen 31, very highly commended; but the best cockerel with a miserable pullet was shown by Mrs. Allsop, and is by far the best we have seen this season. *Dorkings* pretty good in both classes. *Cochins* were also good in colour, shape, and forwardness in the *Buffs* and *Partridge*, but the *Blacks* were rather small and thin-legged, but nice in colour. *Brahmas.*—*Dark* cockerels, first a fine bird, a little raw, but must make a grand one; the second also good. *Pullets* a grand class; the first all that can be desired, the second large, but having a little too much hock for our taste. *Light* cocks a moderate lot, but the pullets made up for these. The class large and competition keen. The first and second

wonderfully well developed, and good in colour and marking. Pen 87 and 88 were a close run, the latter the best marked we ever saw. *Hamburgs*.—Gold-pencils, first a good forward pen; the second had the best pullet, but cock not forward. Pen 93 (Pickles) nice but too young. Silver-pencilled.—First a nice well-grown pair; second not that exhibitor's best, but pretty good. Gold-spangles.—The first far a-head and good throughout; the second also a nice pair. Silver-spangles.—First very good in all points; second a fair pen, but some others too freely manipulated, else their position would have been higher. *Houdans* were the classes of the Show, and left us at full liberty to insist upon the correct type of comb without detriment to other points. In cockerels there were ten, all good in most points. The winners perfect in comb and crest. The second a little raw, but will make an enormous bird. Pullets eighteen, and a rare lot; shape, size, and comb of the highest merit, and nearly all noticed, the prizes in both classes going to Uttoxeter. *Crevins* in pairs were good; the pullets superior to the cocks. *Leghorns* had a class, and these were a smart lot; first Whites (neat in all points) and second Brown. *Turkeys*, *Geese*, and *Ducks* mustered well, and the exhibits were unusually fine. Extra class.—First Golden Polands, second Black Hamburgs, a fair pen of Black Red Bantams being awarded an extra third. Strange to say no provision was made for Bantams, but we understand this will be remedied another year.

POULTRY.—GAMES.—*Black-breasted and other Reds*.—Cockerels.—1, Duke of Sutherland. 2, H. Beldon. Pullets.—1, R. Johnson. 2, W. E. Oakeley. *vhc*. H. Beldon. G. F. Ward. *Any other variety*.—Chickens.—1, W. E. Oakeley. 2, and *vhc*, Duke of Sutherland. *SPANISH*.—Chickens.—1 and 2, J. Powell. *vhc*. J. Walker. *DORKINGS*.—Coloured, except Silver-Gray.—Chickens.—1, J. Walker. 2, W. E. Oakeley. *Silver-Gray*.—Chickens.—1, R. Johnson. 2, O. E. Cresswell. *vhc*. Hon. Mrs. Colville. *COCHIN-CHINA*.—Cinnamon or Buff.—Chickens.—1, C. Sidgwick. 2, H. Tomlinson. *vhc*. Mrs. Allsopp. *Brown*, *Partridge feathered*, or other varieties.—Chickens.—1, J. Wood. 2, C. Sidgwick. *Black*.—Chickens.—1, H. J. Storer. 2, G. C. Levett. 3, E. Kendrick, jun. *ABRAMA POOTRA*.—Dark.—Cockerels.—1, H. Lingwood. 2, E. Pritchard. Pullets.—1, F. Bennett. 2, Horace Lingwood. *vhc*. S. W. Thomas. E. C. Peake. *Light*.—Cockerels.—1, J. Mitchell. 2, R. Percival. Pullets.—1, A. Bigg. 2, F. Bennett. *vhc*. W. Thorn. H. Lingwood. G. E. C. Breeze. *HAMBURGERS*.—Golden-pencilled.—Chickens.—1, H. Beldon. 2, Duke of Sutherland. Silver-pencilled.—Chickens.—1, Duke of Sutherland. 2, H. Pickles. *vhc*. H. Beldon. Dr. E. Snell. Golden-spangled.—Chickens.—1, Duke of Sutherland. 2, J. Jackson. Silver-spangled.—Chickens.—1, H. Beldon. 2, and *vhc*, Duke of Sutherland. *HOUDANS*.—Cockerels.—1, R. B. Wood. 2, I. Ward. *vhc*. S. W. Thomas. I. Ward. Pullets.—1, R. B. Wood. 2, I. Ward. *vhc*. R. E. Wood. J. B. Clayton. *GREY-GEOUSES*.—Chickens.—1, W. E. Upsher. 2, R. B. Wood. *vhc*. I. Ward. *LEGHORNS*.—Chickens.—1 and 2, A. Kitchen. 3, J. Heastie. *vhc*. J. K. & R. R. Fowler. W. Kellett. *TURKEYS*.—1, F. E. Richardson. 2, W. Wykes. *GEESSE*.—1, J. Walker. 2, Dr. E. Snell. *vhc*. W. H. Crewe. *DUCKS*.—*White Aylesbury*.—1, J. Walker. 2, Dr. E. Snell. *vhc*. J. Walker. J. K. & R. R. Fowler. *ROUEN*.—1, Dr. E. Snell. 2, J. Walker. *vhc*. E. Kendrick, jun. W. Meanley, Duke of Sutherland, J. Gee. *Any other variety*.—1 and *vhc*, J. Walker. 2, H. Yardley. *ANY OTHER VARIETY*.—Chickens.—1, H. Beldon. 2, Duke of Sutherland. 3, Howlett & Goodwin (Game Bantams). *vhc*. W. H. Crewe (Malays), K. Hawkins (Malays). *SELLING CLASS*.—*Dorkings*, *Cochins*, or *Brahmas*.—1, H. JUDGE.—Mr. E. Hutton, Pudsey, Leeds.

CARLISLE BEE AND HONEY SHOW.

This was held in connection with the horticultural show on the 6th, 7th, and 8th inst., when the following prizes were awarded:—

Largest and best Harvest of Super Honey, the produce of one Hive.—Equally divided between M. Mitchell and G. Eastwood. *Heaviest and best Single Super, the produce of one Hive*.—1, W. H. Willis. 2, G. Eastwood. *Best Super in Wood, or Wood and Glass*.—1, J. Barratt. 2, M. Mitchell. *Best Super in Glass*.—Prize, M. Mitchell. *Best Sample of Run or Extracted Honey*.—1, T. Tennant. 2, W. Kennedy. 3, T. Street. *Best Sample of Wax*.—Prize, R. Steel. *Best Bar-frame Hive with Super*.—1, J. Drinkall. 2, R. Steele. *Cheapest Bar-frame Hive suitable for Cottager, with floor*.—1, J. Drinkall. 2, R. Steele. *Best Hive on the Storing Principle*.—1, R. Steele. 2, J. Drinkall. *Best Straw Skep and Super*.—1, J. Drinkall. 2, W. Patinson. *Best and Neatest Observatory or Unicomb Hive stocked with Bees*.—1, R. Steele. 2, J. Drinkall. *The most beautiful Ligurian Bees, to be exhibited with their Queen in Glass Hive*.—Prize, J. Drinkall. *Best Bee-feeder*.—2, J. Drinkall. *Best method of quieting Bees during manipulation*.—2, J. Drinkall. *Best Honey-extractor*.—1, R. Steele. 2, J. Drinkall. *Best Super for general use in an apiary*.—1, J. Drinkall. 2, R. Steele. *Best Bee Dress*.—2, J. Drinkall. *Best Drone Traps*.—2, J. Drinkall. *Best Bee Traps*.—Prize, J. Drinkall.

BEE FOOD.

A TRIAL of many years has convinced me that no more excellent food for bees can be made than good wholesome sugar thoroughly dissolved in water without boiling. I find that half a pint of hot water will dissolve 1 lb. of sugar in a few minutes after careful stirring. I generally prepare a canful at a time, which holds 5 lbs. of sugar and 2½ lbs. of water. It is made and ready for use in a few minutes, and is none the less wholesome if given to the bees while still warm.

I used always to boil the sugar, but found that there was no certainty as to the consistency of the syrup. Sometimes it was too thick, overboiled in fact, and at other times it was too thin. Now it is always uniformly the same. I may add that I get a very excellent moist sugar for 3d. per lb., perfectly clean and wholesome.

I have nearly done feeding my bees for the present, but I shall give them a pound or two more all round towards the end

of October, so that food may be in the open cells when winter comes.—B. & W.

OUR LETTER BOX.

THE CAYUGA DUCK (*A. H. Z.*).—The Cayuga is not sufficiently known and kept to be one of those birds, like Rouens or Aylesburys, whose points and descriptions are thoroughly known and admitted. They have no advantage over these other breeds to cause them to be successful rivals. Their colour should be as dark as possible, if quite black so much the better. There is, however, almost always a brown tinge on it, and this often shows on the wing. We have seen them without it, but it is immaterial. There should be a white mark on the neck almost a collar. The great point is weight, as they have no pretensions to be birds of plumage. The heaviest, therefore, will always be the best.

MOULTING COMMON CANARIES (*Canary*).—The processes of moulting Canaries varies much; but as you ask the question how "common Canaries" should be moulted, we would advise you to bring into requisition a spacious fly-cage (one adapted for some half-score or score of Canaries); or if you have a spare room fix therein some long perches, not to cross each other, and throw in the stock of birds, which will do well on ordinary Canary diet, and the floor strewn with grit sand, and supplied with a suitable spacious shallow vessel for the birds to bathe in. A seed-hopper to hold the food, one with three or four round holes for the birds to feed from, is preferable to an open seed-trough wherein the birds get and soil much of the seed. Before supplying the seed sieve it and mix therewith a pinch of the flowers of sulphur. Let the seed consist of canary, small hemp, millet, linseed, and groats, and now and then a little scalded rape seed. To prevent the birds pecking each other during moult, draw a thickish cloth before the window, so that the room may be in a state of semi-darkness. Occasionally a little may be added, crushed plain biscuit, and a piece of suet may be given. With this treatment your birds should thrive.

EMPTY COMB IN SUPERS (*Robeston Wathen*).—Supers filled and partially filled with empty combs are valuable and should be carefully kept till next year. Wrap them up in paper or cover their mouths like preserve jars to keep moths from the combs, and place them in a dry room or cupboard for the winter. Your bees will take to them readily next summer and give a good account of them.

GUINEA PIGS AND RATS (*Subscriber*).—Some years ago we had a number of Rabbits in a shed, and kept Guinea Pigs with them, not to deter rats, as for the time we had none. They came as they always do where there is food, and when on short commons they killed and ate the Guinea Pigs.

REMARKS.

- 5th.—Very bright morning and forenoon, less bright in afternoon, hazy between 6 and 7 P.M.; starlit night.
- 6th.—Brilliant morning and bright pleasant day, rather stormlike between 5 and 6 P.M., but fine though rather hazy afterwards.
- 7th.—Splendid morning and fine day; rather cloudy and rainy-looking from 4 to 6 P.M., but fine after.
- 8th.—Very bright fine day throughout.
- 9th.—Fair but not bright in the morning; beautiful day, and a very bright night.
- 10th.—Slight rain in early morning; damp, dull, and sunless nearly all day, but rather less so between 5 and 7 P.M.
- 11th.—Fine forenoon, very dark from 3 to 4 P.M.; very heavy rain for a short time after 3.30, lighter rain fell for about an hour; fine afterwards. A fine week, slightly cooler than the previous one, no rain until the last day.—G. J. SYMONS.

COVENT GARDEN MARKET.—SEPTEMBER 12.

THE almost universal failure in fruit crops has caused our market to look very bare lately, Nuts and Apples alone reaching us in any quantity; of the former there bids fair to be the largest crop known for many years. For Pears and Plums we are entirely dependant upon foreign goods, prices being exceptionally high. Pines are in fair demand, and will now realise good figures for some little time. Business quiet.

From observations taken near London during forty-three years, the average day temperature of the week is 66.4°; and its night temperature 44.8°

ERRORS IN POTATO MANAGEMENT.

THE Potato disease has baffled the science of the age, and it will continue as long as Potatoes are grown if the present mode of treating those to be used for seed is carried on. I believe the blight to have been more or less in existence long before 1845. I recollect quite well seeing a black or diseased Potato now and again when they were cooked, and I said so at the time the blight was so virulent in 1846; and I remember when the Potato pits were opened seeing a good many rotten ones, and no one will persuade me that such was not the disease that prevails at the present time. It was then so trifling that no attention was paid to it.

I am decidedly of opinion that the primary cause of the disease arises from the way the tubers are kept during winter and early spring. The tubers for seed are stored with those that are to be used for cooking, and at storing time they are put into pits, as they call them in Scotland, and pies in England; these pits are from 3 to 4 feet broad, and there will be 5 to 8 cwt. in a running yard. There is a thick coating of straw put over them to exclude the frost, and then 6 inches or so of soil is put over the straw, with a little air at top for weeks, or till sharp frost sets in, when they are, as a rule, covered up so as no air will get in to damage the tubers. Some farmers put a thick covering of straw on the top and no soil above it. If the weather happens to be fresh and mild the tubers will begin to sprout in January or February, and particularly so if a portion of the tubers are diseased. The moisture arising from the decaying tubers sets them a-growing, then the pits have to be opened and the sprouts and diseased tubers are removed; and anyone the least acquainted with vegetable physiology must believe that the sprouting of the tubers for seed tends to weaken the constitution of the Potato, and ere the planting season comes round, if the weather happens to be of a mild sort, the sprouting goes on and increases the evil. I have seen the Potatoes growing up through the soil and quite green in early spring. I saw it this year, and it is a very common occurrence; and during the months of March and April the small-sized tubers are sent to the English farmers. Under these circumstances, which are grave facts, need any person with a head on his shoulders wonder at the Potato succumbing when an ungenial season occurs? But for the spurious mode of treatment named the Potato would be far more able to resist a season not quite adapted for it, as it is a fen plant more than an aquatic. This I fully believe is one of the causes, and the chief one, of the disease.

Since I remember anything about Potatoes, and up till 1845 and 1846, the Potatoes grown in the Lothians were London Dons, *alias* Caligos, a very fine variety; Blue Don, Glasgow Buff, Perth Red and Blacks, and they were all first-class sorts, far finer in flavour than the Regents. The Flukes and Lapstones are almost equal to any of them; the flavour of a Fluke is equal to the

Don. Up till the blighty season these sorts bloomed and bore seed in great profusion, and the haulm was laid prostrate from the weight of the apples, and people used to gather them to feed pigs.

During a period of fifty-five years, which I remember, I never heard of any person sowing seed to raise new sorts, which no doubt a kind Providence intended for the very purpose, and there was no need for better sorts; but roots, like human beings, may get weak and die out, hence the necessity of rearing new sorts. This, I believe, is the second cause of disease; for I believe in a combination of causes far more than many people imagine, simply because they do not use their brains and look to cause and effect. The third cause arises from the fact that the Potato fields are too highly manured with home manure, and which is quite sufficient; but to increase growth and try to get heavy crops a quantity of guano or other artificial manures is sown on the land, and before the end of July, or not long after it, the Potatoes are met in the drills, and before lifting-time they are warped together like a field of Peas; and if the weather is at all moist the ground gets saturated, and neither sun nor wind can get near them, and depend upon it this causes disease in other plants as well as the Potato. This state of matters ought not to be. The Potatoes should be planted wide enough to allow the sun and air to get between the rows, and such would tend to dry up the superabundant moisture. But the forcing the Potato so much with artificial manures is a great mistake, and I presume such was not long in use before the first blight. I was in Lincolnshire and Yorkshire a few years ago, and the blight was very bad, and between Doncaster and Crowle there were large level fields of Potatoes and warped together so that neither sun nor air could get in to warm and dry the soil.

The fourth cause is the preparing the seed for planting. In England small-sized roots are used for planting, and it is a very rational idea. In Scotland such never used to be done till very recently. They are planting seconds to some extent; and if cutting the large tubers is carefully done and planted at once they will do as well as need be. But possibly some tons of seed are cut and rain sets in, the seed is muddled together into a shed or barn, and at times they get heated and may remain in this state for days. It is no rare matter to see a field of Potatoes with a Potato within 6 feet of each other; this I have often seen in this great Potato country. Where small roots are used there are no blanks worth talking about, and the Potatoes when cut for planting are in a growing state, as the sap is in full force and runs out of the sets, and without a doubt this also tends to weaken the constitution of the Potato. They may grow I admit, but puny curly stems are the result and a poor crop. These, in my opinion, are the causes of blight, and not the wet seasons entirely, as I have seen as wet, sultry, thundery weather before 1845 as I have seen since. And now that there is a sort of consumption in the constitution of the Potato I do not wonder at all that a wet season proves fatal to them. There is a close analogy between animal and

vegetable life; and let a man abuse what may be a sound constitution by intemperance in eating or drinking for a short time, and then bleed, blister, and dose him with medicine, yet should an epidemic prevail he is sure to succumb, while those who have acted in unison with the laws of Nature are more likely to live. This is a well-known fact, and I do not wonder at it. Having pointed out what I think the cause of disease, and which is a serious matter for the million when blight is general and one-half of the tubers are only fit for cattle or swine. A farmer will not grumble from the fact that he gets double or treble the value for what is good, and has less driving with his carts to railway stations, and he has feed for his cattle beside. This is no theory, it is a fact; it is the consumers that pay for the loss of the crop.

The next point for consideration is, How is the matter to be obviated? Are we still to go on in the old use and wont manner, or turn our attention so as to avoid such a dire calamity as the loss of this valuable esculent? I would suggest that the Potatoes for seed should be kept in a cool exposed place, and never be allowed to sprout till after they are planted; and by raising new varieties from the hardiest sorts and treating them in a far more scientific manner there is every reason to believe that in a few years the Potato will be restored to its pristine vigour. Possibly it might be wise in the powers that be to look into the matter as they do with cattle disease and the Colorado beetle, and it is my candid opinion that the one is as necessary as the others.—J. ANDISON, *Ormiston, Edinburgh.*

AUTUMN PRUNING OF FRUIT TREES.

AGAIN I would remind all fruit growers of the importance of getting forward with such pruning as may be safely done at this time of the year, so as to diminish as much as possible the work left for the short dull days of early winter. Gardeners are gradually coming to acknowledge the evils of spring pruning, at least there is less of it done every year; but as a body we are very conservative in our notions, and cling to old practices long after they have been proved to be in error. I should think there is not now one intelligent gardener in Britain who would defend spring pruning; if there is I should like him to give his reasons for so doing. I have given my reasons more than once for insisting that all pruning should be done before Christmas, but being convinced that it should be done and getting it done are different things; and I believe that spring pruning, where it is now practised by men who deserve the name of gardeners, is simply from necessity—from pressure of work at certain seasons. Now, there is no garden of any pretensions where it is possible to get all pruning done between the fall of the leaf and Christmas unless summer and autumn pruning are thoroughly carried out, but where there is not a separate staff kept for each department there is a danger in these days of excessive floricultural millinery that the summer attention to fruit trees will be very limited, and consequently there is the greater necessity for getting at the work in early autumn.

Although the gardener's year has no beginning and no ending, unless it is beginning and ending every day, September is the month in which there is a sort of turning point; all arrears are then brought up unless one is hopelessly in a muddle, plans are roughly carved out for the following season; we have, or ought to have, a breathing space for a week or two to take stock, note down our shortcomings, and if possible travel a little to take a few wrinkles from our brother gardeners. In any case we must begin again in earnest some time during September, and work with all possible diligence before the autumn gives place to winter.

The most important thing perhaps at this season for the gardener to attend to personally, unless he is so fortunate as to have assistants with the requisite skill, is the getting the growths of his wall trees ripened. Often he is obliged to wait till the fruit is gathered before he can thin out sufficiently; but unfortunately there is little necessity for that this year, and consequently there is every chance to have a thorough overhauling and re-arrangement of branches. There is no time like the present to cut out old branches of whatever size which are becoming bare, or long unsightly spurs bearing shoots too (which alas! only bore flowers) that are not wanted another season for furnishing, and stopping the points of unripe growths. Bear in mind that light, air, and the warmth from the wall are necessary to ripen the growth made this year previous to August; that made subsequently will not ripen under any conditions, and if therefore after doing all the

necessary thinning there is still more foliage than can be exposed to the light, the latest and greenest growths may be shortened, and this will reduce to a minimum the work to be done after the fall of the leaf.—WM. TAYLOR.

ROSE DIFFICULTIES.

YEAR by year the number of amateur gardeners increases, notably the growers of Roses. It would be an interesting document which should exhibit the various pursuits out of office of the clerks of this great City. I think gardening would be found to occupy one of the largest, if not the largest section. And why? Because there is nothing which gives so great an amount of pleasure, exercise, and subject of thought. Many of us, I am afraid, cannot say with Bacon that gardening is the purest of human pleasures, because we have only a limited portion of time in which to pursue it, and we all feel a certain amount of disappointment at something which we try at but do not accomplish. But it is not to write about the delights that I wish, but to pour into your willing ears some of the many troubles of my garden. Before I begin let me thank our friends "WILD SAVAGE," Mr. Hinton, and others for the many excellent hints which we get from your columns, for I am glad to say the *Journal of Horticulture* is always held up as a great institution with us.

I am a City clerk—not much leisure except early morning and a stray hour on the Saturday, but I do what I can. Last September I purchased a cottage and garden of about a quarter of an acre; and a third of this I have planted with fruit trees, another third is occupied with miscellaneous subjects, and the other third is given up to Roses, for you must know this is the flower I love. My garden had been shamefully neglected for several years, and presented when first I went into it a forest of weeds, but these were well cleared out, and have, thanks to the Dutch hoe, been kept under. I chose the very best quarter I could for the Roses. The ground is situate twelve or fourteen miles from London and stands high. It is well protected on the east and north by trees which break the wind, and a good wood fence protects it from the west. The soil is a strange mixture. The surface looks a moderate garden soil; taken in the hand it binds together, and therefore cannot be called sandy: in places the subsoil is clay, in other places sand, but the whole garden is well drained, yet cannot be called dry or thirsty. I planted fifty standards in a bed, or rather a portion, for mine is not a place of fancy beds; and these had but little manure when planted and afterwards had a fair mulch of stable dung, which was forked-in carefully in the spring. Afraid that my soil was rather light I also planted about sixty on Manettis, not choosing variety so much in the selection of sorts, but such as I thought would give an abundance of flowers—Monsieur Woolfield, Général Jacqueminot, Sénateur Vaisse, John Hopper, Paul Neyron, Madame Charles Wood, Etienne Levet, Alfred Colomb, Paulin Talabot. These Manettis had all a liberal supply of cow dung, or rather cow droppings (no straw), which was fresh. Pruning was effected rather closely on the standards and very moderately on the Manettis. June came, I lost my Gloire buds first crop with frost, and the first Rose out was Paulin Talabot. I quite astonished my fellow clerks who grow Roses with the blooms I was enabled to bring of this Rose, which deserves to be grown a great deal more than it is.

At the end of June, after keeping clear of grubs and green fly, a pest which has baffled all I can do broke out—mildew. Paulin Talabot commenced. I got soft soap, mixed it with soft water, applied it to the leaves with a large paint brush, washed it off; the result was blistered or discoloured leaves, and for a day or two a victory—but ah! Etienne Levet, Alfred Colomb, The Duke, and Edward Morren are all affected. I am recommended sulphur, and forthwith get a flour-dredger and sulphur; it has but little effect. Then I tried sulphur and soft soap together; no use. Then I hear that soot is the remedy, and forthwith instead of yellow showers out of my dredger, black is the favourite. I syringe, I groan—all no use, though I spend hours of toil. By the end of July the whole of my Manettis, with the exception of a row of unbudded stocks which seem to triumph over their brother slaves who are budded, all are more or less covered with mildew. Leaves are white, bloom buds are thoroughly encrusted on the stems, the thorns on vigorous shoots seem to be storehouses of the white substance, and the enemy has become so strong that it is almost impossible to do anything, and yet these diseased plants have shot up vigorously shoots 7 feet high are on

many sorts. Nor can I complain of quantity of flowers; I cut a very lovely batch to-day for the sitting-room glass, and I could almost hope for a cessation were it not for the little clots of white which appear at intervals (close to the thorn) on even the strongest shoots. Well, unfortunately, I have been no better with the Briars; they have all suffered from this mildew, and though they are now covered with blooms, small ones it is true, they are literally wrecked with this disease. Is it the soil? When I read that when Briars will not do because of the absence of a stiff soil it is preferable to plant Manettis, I can understand it, but I cannot understand why all, Briars and Manettis, should be so terribly punished. There must be a reason. I have watered with chamber slops, urine, &c.; my cow dung on the Manettis was new, the contents of a ditch containing nothing but slop water were resorted to, and there has been a good deal of decaying substance applied. Will any of these account for the disease? It has even attacked Gloire de Dijon, Salet (Moss), and the Monthly China, yea, and I find it on some shoots of Briars which have not been cut off. What is best to do? I have laboured every spare minute, and am fairly wearied and cast down. Will "WYLD SAVAGE" or the "PARSON'S GARDENER" spare me a few minutes, and would they like to see some of the shoots? Would you feed or starve? Would you give them dung or chemical manure? Would you cut them, or what? I am not enough of a naturalist to know, but is the disease on the backs of the Laurel leaves, which I find to be very prevalent in Surrey, the same as Rose mildew? It looks very like it, though I observe that the leaves of the Laurel seem eaten entirely up, while the leaf of the Rose curls and withers. I have seen Laurels in many parts all suffering from this mildew. I am sorry I have taken up so much time, but you have so kindly answered before that I venture again.

Another query—I have a tarred close fence, faces towards the east, gets all the morning sun. What had I better plant against it? The border is about 18 inches wide. Would Apple trees trained on wires do? or would some laths be better than wire? If Apples, what sorts would be best? I find that Hawthornden and Court-Pendu-Plat make capital espaliers. Will Cox's Orange Pippin do the same? I have also a north or north-west fence, gets a deal of sun: would any fruit tree besides Morello Cherries do well here? The fences are close, so that the wind does not get through, and are about 6 feet high. Can you also tell me the name of a very pretty hardy climber which is now filled with red berries? I see it on some of the cottages, and would it do with a north aspect? Would a Buddlea globosa do on an eastern wall? Another query—I have three plants of Thomas Mills Rose, they are very vigorous, but they will not bloom. Is this Thomas Mills' character? if so he must find another home. Not a single bloom on the three trees, though they are large and occupy space.—CITY CLERK.

DEVELOPMENTS IN FERNS.

FERN literature is almost daily increasing; this shows evidence that Ferns are in great favour with the gardening world; besides their being in favour, it shows that their cultivators desire to know more about them than the books in the past or their experience tells them. Ferns altogether are very interesting plants, and their developments, which are so unlike those in other vegetable families, are a source of pleasure and study to many people.

The changes of form in Fern-life to all pteridologists are mysterious, because the cause of the developments are unknown. A few students have apparently tried to fathom the mystery, and because they cannot find the source or the motive-power of the changes some of them have, perhaps too hastily, concluded that the variations that we see in one or other species of Ferns are abnormal and unnatural growths. This conclusion, however, is not altogether satisfactory, although it is for some people an easy way of disposing of a difficulty which may come to be more thoroughly understood as knowledge increases. To my mind there must be laws which govern the growth of these interesting plants as in other natural phenomena, and daily I am more and more convinced that such is the case, because as time rolls on most species of Ferns (my experience is in British Ferns) produce the same characteristic forms of growth in their different families which are commonly called freaks of nature. If we examine *Asplenium Trichomanes imbricatum*, *Lastrea Filix-mas crispata*, *Athyrium Filix-femina* *Simpsonii*, *Blechnum Spicant imbricatum*, *Scelopendrium crispum*, &c., we find their fronds contracted and imbricated,

and though the varieties named belong to separate families they all assume this peculiar form of growth. Again, crested habits of great similarity are met with in *Lastreas*, *Athyriums*, *Blechnums*, *Aspleniums*, *Adiantums*, *Osmundas*, *Cystopteris*, *Scelopendriums*, *Polypodiums*, *Polystichums*, &c. These same families, or most of them, produce their incised, cornuted, crisped, depauperated, marginated, and other styles of growth. After thinking over these peculiarities, which are found in common in most Fern families, it seems to my mind that if they were freaks of nature there would be great irregularity and nothing in common among the developments in the different species. But such is not the case. To even common observers there is a great similarity of aim, if I may use the expression, in the attempts of Ferns of all sorts to change the outline of their fronds into definite types of form, recognised not in one or two Fern families, but through all the genus. With this evidence before us, it seems that a power is working through Fern-life according to rules which produce by its action in all the Fern species a changing of the general outline of their fronds to other definite shapes. It must be acknowledged that the unknown natural force, which is changing rapidly in these days the appearance of Fern fronds, works more quickly in some families than in others; but I believe its effects may be traced in all, or nearly all, of the British and many of the exotic species. The unknown force appears to work strangely, although it seems to move one step at a time. Sometimes it at one move develops a crested variety, as was the case when *Lastrea Filix-mas* took the *cristata* form. Again, this latter variety brought into existence a narrowed form known by the name of *Lastrea Filix-mas cristata angustata*. In the following case the contraction came first, when *Lastrea Filix-mas* took the *crispa* or imbricated habit; after which *Lastrea Filix-mas crispata* generated the crested type, which is very dwarf, and known under the name of *L. F.-m. crispata cristata*. Another almost parallel case is that of *Athyrium Filix-femina curtum cristatum*. In the first place *Athyrium Filix-femina* assumed the *curtum* habit, and the spores from that type generated a crested form. The march of the unknown force might be traced many steps amongst the *Athyrium* and *Scelopendrium* varieties, but time and space will not allow us to follow in its path. From these three cases mentioned and others of like nature it may be inferred that the unknown natural force is an active and progressive power, its goal, like its starting point, being unknown: therefore we may presume to expect that though the Fern varieties we have may generate their like, yet they may yield spores which progressively will give to us forms of Fern-life of which we can have no conception.

I should like to add a little more upon this matter, also upon the germination and hybridity of Ferns, but I must not now.—G. SMITH, *Kendal*.

CRYSTAL PALACE.

YEAR by year the ornamentation of the grounds at this great public rendezvous appears to improve. Certainly they have never been more effective than they are during the present season, as all must admit who inspect them. They are attractive when viewed from various standpoints, but from no point is the effect more imposing than at the entrance to the grounds from the low-level station. To the right is the broad receding lawn and massive beds of *Geraniums*, &c.; to the left the still broader and extremely fine beds of *Dahlias*, with masses of *Tritomas* and *Helianthus* in the distance; and in the front is the artistically arranged bank round the roseray, and the series of round carpet beds on the sloping lawn, which must rank amongst the most effective beds in any of the public metropolitan parks and gardens.

A few of the isolated beds on the lawn may first be noticed. The best of the brilliant scarlet *Geraniums* is *Lady Constance Grosvenor*; it is extremely floriferous, lively, and bright. *Vesuvius* also is excellent. The best pure pink variety is *Cleopatra*; and *Amaranth*, lilac pink, is very good. The best of the salmon is *Gloire de Corbenay*, and of the whites *Madame Vaucher*. *Waltham Nosegay* is unsurpassed as a crimson, and as a crimson-scarlet *Bonfire* is still pre-eminent. The round beds of the varieties named, edged with contrasting colours, are as good as *Geranium* beds possibly can be. Some large V-shaped beds at the corners of the walks are splendid, especially one planted with a centre of *Serena*, satiny pink, a broad band of *Bonfire*, and an edging of *Robert Fish*. Nearly equal to it, however, is the corresponding bed with

Duchess of Sutherland, crimson, in the centre, a band of (Cleopatra, and a margin of Vesuvius. Some Calceolaria beds (Golden Gem) are very fine, quite the best I have seen this year. A few mixed beds are pleasing, notably a silver variegated Geranium and Verbena venosa edged with Robert Fish, and a bed of variegated Tropæolum Minnie Warren associated with dwarf Ageratum Douglasii. This Ageratum is new; it is very dwarf, massive, and rich, blue rather than lavender, and

an acquisition. Countess of Stair is also employed effectively, but it is not so dissimilar from Imperial Dwarf as is the darker Douglasii. Mr. Wildsmith's Petunia Lord Eversleigh, purplish plum colour, is a fine bedder; and one of the most effective of Lobelias for edging large beds or for a second line in small beds is Glow-worm, raised by Mr. Rutland at Goodwood. It is extensively planted at the Crystal Palace, and its deep glowing colour renders it a general favourite.

Fig. 46.—Scale of half an inch.

1. Alternanthera versicolor.
2. A. amena.

3. Leucophyton Brownii.
4. Pyrethrum Golden Feather.

5. Echeveria secunda glauca.
6. Sempervivum montanum.

The carpet beds have been planted so as to be effective from a distance while they will yet bear the scrutiny of close examination. Beds arranged with soft neutral colours are very chaste and pleasing when closely examined; but the majority of visitors to the Palace do not submit the combinations of colour to microscopical examination, hence bright colours have not been eschewed by Mr. Thomson, yet there is no suspicion of mere gaudiness. Cheerfulness and uniformity has mainly been imparted to the beds by a simple ring of Golden Feather. This contrasts admirably with the broad expanse of green grass, and the beds thus edged have a more satisfactory appearance than have others which are edged with silvery-foliated

plants. The characteristics of the carpet arrangements are boldness and simplicity rather than novelty and intricacy. For instance, one bed (it may be referred to as No. 1) contains a tracery of the trailing variegated Geranium Duke of Edinburgh, with panels of Mentha and angles of Alternanthera and Echeveria. No. 2 has a cross of Iresine Lindeni, panels (half circles) of golden bicolor Geraniums Black Douglas and Veronica incana, and a tracery of green Saxifraga and Alternanthera. No. 3 has an interlocking tracery of Lobelia Blue King and Golden Feather, with panels of Echeverias, Alternantheras, and Coleus. No. 4 has a diamond of Tagetes (what a charming green carpet plant this still is as managed here!), a broad

surrounding belt of Golden Feather, terminating in circles at the points of the diamond, another band of *Veronica incana*, angles of *Alternanthera*, and a ring of green *Saxifraga* next the margin of Golden Feather. No. 5 has interlocking links of Golden Feather and *Echeveria*, the centres filled with *Alternanthera amena*, with angles of *Alternanthera versicolor*, *Sempervivum montanum*, and *Leucophyton*. No. 6 has a star of *Iresine Lindeni*, with bands of Golden Feather, *Tagetes*,

and *Lobelia*; angles of *Veronica incana*, and ring of *Alternanthera magnifica*. These are a few typical beds "taken as they come," not selected, and all of them and many more are excellent. The plants named and their association may be suggestive. As to the designs, they are founded on simple geometrical rules, and anyone with a pair of compasses or a peg and string need not be long at a loss for a pattern. Diagrams of two beds are submitted, which afford an idea of the

Fig 47.—Scale of half an inch.

1. *Iresine Lindeni*.
2. *Saxifraga* sp. (green).

3. *Pyrethrum Golden Feather*.
4. *Pelargonium*, or *Geranium*, Black Douglas (bronze).

5. *Veronica incana* (grey).
6. *Alternanthera magnifica*.

character of the patterns which prevail throughout the series; but all the beds are different. They are about 12 feet in diameter.

The circular bank round the rosety, which is 9 feet wide, is very beautiful. It is planted somewhat as follows:—In the centre of the bank, at intervals of 9 or 10 feet, are somewhat kite-shaped pendants of *Centaurea ragusina*, surrounded and connected with *Iresine Lindeni*. In the front of this are zigzag belts of Golden Superb *Geranium*, Blue King *Lobelia*, and *Leucophyton*. Next the walk is a margin of *Echeverias*, and between them and the *Leucophyton* are angles of *Alternanthera paronychioides major* in brilliant colour. At the

back of the *Centaurea* and *Iresine* the large half-circular spaces are filled with *Geraniums*, pink and scarlet alternately, backed with a row of silver variegated *Geranium* next the green edge of the *Roses*. The balance of colour in this bank is admirable, and the general effect of the arrangement is extremely good.

In fine contrast to the bank and carpet beds in connection are the large *Dahlia* beds on the adjacent lawn. These are bedding *Dahlias*, which bloom earlier and more profusely than the show varieties. The plants here have been rich masses of bloom for some time past, and will continue gay until destroyed by frost. Why are not these *Dahlias* and the charming bouquet

varieties more generally grown? Nothing can be finer from the beginning of August onwards. The beds are round and very large. They are mostly planted with a mixed variety of show sorts in the centre, with contrasting rings of two bedding varieties. Of these Rising Sun is the best dwarf scarlet, Zelinda the best maroon, Alba floribunda nana the best white, and Yellow Pet the best yellow. The last-named is a comparatively new variety raised by Mr. Turner of Slough. It grows $2\frac{1}{2}$ to 3 feet high, is extremely floriferous, early, bright in colour, and altogether good. During the early part of the season these beds were gay with Hollyhocks and Delphiniums, between which the Dahlias were planted. Some of the beds are edged with Golden Feather and the others with Gnaphalium lanatum, but the Golden Feather is the more effective. The beauty of these beds is enhanced by the great extent of lawn surrounding them and its excellent keeping. A grand bed of Tritomas, Phloxes, and double yellow Helianthus demands notice. It glows like a fire from the great mass of brilliant colour. Tritomas also at the foot of the southern terrace wall, which in one part is covered with Roses, have a fine effect; and the old-fashioned Monthly China Rose, which is employed as an edging to some of the Rhododendron beds, is still blooming freely, and will continue doing so even after the Dahlias and most other flowers are destroyed by frost.

On the upper terrace next the building are many well-filled carpet beds, and the chain of beds in the panels are filled with the same established bedding Geraniums noticed above. Some alteration has been made round the pedestal vases on this terrace. Formerly a small bed encircled by a ring of turf, then another bed, were arranged round each vase; but now the turf is removed and each pedestal stands in a large bed. The centres of these beds, being Dahlias surrounded with Geraniums and edged with Glow-worm Lobelias, have an excellent effect. The alteration noticed is certainly a great improvement.

The interior of the Palace is equally worthy of inspection. The western wing contains many fine Palms, and dead trunks of Tree Ferns are turned to account as supporting mediums for Ferns of smaller growth. The effect produced by these, crowned as they are with healthy plants of Lomarias, are quite ornamental. In the adjoining structure are some fine trees, real trees, of Camellias; also Oranges, which the public rarely see. A structure adjoining the aquarium—a continuation of it—is decorated with Ferns and other ornamental-foliaged plants. These wings are mere adjuncts to the huge building, the plants and trees of which are remarkably clean and healthy. The groups of plants—Dracenas, Musas, &c., in the Alhambra Court and the Fern Grotto there are well worthy of inspection, and the manner in which seedling Dicksonias are raised in the Palace is noticeable. Round some of the fine specimens planted out in the borders ridges of peat, a few feet from the stems, are placed. These are kept moist, and seedlings spring up by thousands; but on the level ground, which is also kept moist, the spores do not germinate at all. Why? The answer is very simple when once Mr. Thomson tells it. Because they are washed away or too much disturbed by the heavy watering which is given to the roots. Sufficient Dicksonias will soon be raised to plant the building. The hanging baskets overhead are extremely fine this year. They are mostly filled with trailing Cape Geraniums brightened with common Tropaeolums. It is surprising that the plants in the colossal building can be preserved in such good health and kept so clean by a body of only seventeen men, who have also an extent of preparing houses to attend to equal to those of a good-sized nursery. In this department is a splendid collection of Chrysanthemums in pots, about two thousand plants, which will make a grand display during the late autumn months. The Crystal Palace never looked better, if as well, as at the present time, and it will repay a visit to all who are desirous of seeing garden decoration well and effectively carried out.—J. W.

GRAPES CRACKING.

At page 220 you tell "M. R. P." that the cause of his Grapes cracking is the Vine supplying sap faster than the skins of the berries can expand. This is quite correct; but it certainly has its causes, and I think its remedies. Keeping the shoots closely pinched when the Vine is growing vigorously causes the sap to flow stronger into the fruit. Where Vines are growing close together, as they are in most cases, it is impossible to let the side shoots run far enough out to use the extra sap. I have tried a plan to counteract this this season,

which, so far as I am aware, is original, and it certainly answers the purpose well. The laterals on the Vines have been pinched in the ordinary way up to the last three or four shoots from the top. On these the laterals have been allowed to grow. This gives a greater number of leaves to supply with sap at the top of the Vine, and instead of a great pressure of sap running into the side shoots and berries the most of it flows to the top, where it is no way restricted. Under this treatment there was not a single berry cracked or split this year, and a noted Grape-grower told us the other day that our Vine wood of this year was very luxuriant. These top shoots are not taken off until the wood has become brown and the flow of sap declining. They do no harm through giving a little extra shade to the top, and as the mass of leaves break the current of cold air which sometimes enters at the top lights they do much more good than ill.—A KITCHEN GARDENER.

CARLISLE INTERNATIONAL SHOW.

SEPTEMBER 6TH, 7TH, AND 8TH.

CUT FLOWERS.

IN the horticultural world, whenever it was wanted to indicate the most miserable day on which a show was ever held, the first day of the provincial Show of the Royal Horticultural Society at Birmingham always came to the lips; but I fear it must in its turn give way to the first day of the International Show at Carlisle, for a more miserable, wretched, dreary one never marred the hopes or disappointed the well-grounded expectations of an energetic Committee. The Castle Sawceries were indeed saucers, for the heavy rains of the past few weeks had converted the meadows into sponges, so that when such a down-pour came as it did on Thursday it had no chance of getting away, and the dismal swamp could hardly have more deserved its name. By-the-by, the derivation of the word Sawceries was given to me as that of Saugheries, which in broad Scotch means the Place of Willows. Some idea of the condition of things with regard to cut flowers may be imagined when I say that the largest grower of Gladioli in Scotland had not one spike in bloom and had dug a trench a foot deep round his beds to carry off the water, and that while I in Kent had been gathering ripe Figs from my standard trees Gooseberries were not ripe in Scotland. What, then, was to be expected? Gladioli were almost unrepresented, Hollyhocks by six of the most rubbishy spikes ever seen, Asters indifferent, and the only flowers that were at all presentable were our good friends the Rose and the Dahlia. Of these some good boxes were shown.

Mr. Cranston of Hereford sent some fine Roses not for competition; and the executors of Mr. J. Harrison, Darlington, contributed a good stand consisting of Charles Lefebvre, Mlle. Marguerite Dombrain, Alfred Colomb, Princess Beatrice, Marie Baumann, Alice Derreux, J. Stuart Mill, Etienne Levet, Comtesse de Serenyi, Mons. E. Y. Teas, Francois Michelin, Madame Bravy, Beauty of Waltham, Catherine Mermet, Leopold Hausburg, Sir Garnet Wolseley, Belle Normande, Augusta Rigotard, Emilie Hausburg, Louis Van Houtte, La France, Dupuy Jamain, Lælia, Thomas Mills. There were only a few boxes of Dahlias, the best being those of Messrs. Dickson & Son, Newtonards, County Down, Ireland, for Rival Harris, Julia Wyatt, Henry Walton, Cremorne, J. McMillan, Mrs. Stoncomb, Dr. Moffatt, James Cachet, Hugh Miller, Vice-President, Charles Backhouse, Jenny Austin, Negro Boy, Lady Gladys Herbert, John Bennett, Alexander Cramond, Rev. J. B. M. Camm, John Standish, Royal Queen, and Ovid. In twelve fancies Mr. Dickson also first with Laura Haslam, Sparkler, Coronation, Mrs. Sanders, Miss L. Sage, Mrs. Brown, John Salter, Fanny Sturt, Richard Dean, and Rev. J. B. M. Camm.

I had hoped to have seen some good Gladioli from my friends Lord Hawke, Mr. Galloway, Mr. Orichton, and others; but alas! there were but two stands, one a most miserable stand of seedlings in the nurserymen's class, and one in the amateurs' exhibited by Mr. R. Gray, gardener, Killorchan, Castle Girvan. In this there were three good blooms—Aramis, Adolphe Brongniart, and Lacépède; the rest were indifferent. In no other class except Pansies was there anything worth recording, and of these some good stands were shown, although the flowers were small.

TABLE DECORATIONS.

The valuable prize of a cup, value £25, offered by Lady Muncester, brought together eleven competitors, and I may with safety say that some of them were as creditable as ever I saw set up, although as usual there was much questioning of the Judges' decision; but in this the first prize was excluded, for even the defeated competitors acknowledged its excellence. It was set up by Mr. James Cypher of Cheltenham, and displayed admirable taste. The three centre vases were light and elegant; the sprays of Orchids, the flowers of Gloriosa superba, and the fronds of Maiden-hair Fern had a most pleasing effect. The table was not overcrowded, and all the appointments were good.

The second prize was, I think, wrongly awarded: the tables were too full, and the articles containing the flowers and fruit were arranged in three straight lines. One table was conspicuous for a heavy epergne which seemed as if it required someone to hold it up. Another was terribly overloaded, but seven out of the eleven were arranged with taste and skill. There was a very large number of bouquets, and some of them evinced very great taste, notably those of Mr. Perkins of Leamington, being neither heavy nor overcrowded. It is evident that, in some parts of the country at least, a better taste in these matters is beginning to prevail, and that we shall no longer have our eyes vexed with the inartistic abominations of former days.

It was in truth a great Show, but no attempt at artistic arrangement was made anywhere, and success depended on the excellence of the exhibits alone; and terrible indeed was the scene. Never shall I forget the luncheon, from which I beat a hasty retreat, although many even of the ladies sat it out. Sir Wilfred Lawson did not remain for it, but assuredly he might have done so, for his favourite element was there in abundance. Oh that I had the pencil of poor John Leech to portray the portly form of my reverend brother of Causton, as in broad-brimmed canonical hat and great coat he sat crouched under an umbrella sipping half-cold soup! It was a sight well worth seeing. I can only hope that better fortunes dawned on the promoters on Friday, or else there must be a heavy reckoning for the guarantee fund. It would be unfair to close these few notes without acknowledging the excellent and thoughtful accommodation made for the Judges; nothing could have been better, and one and all appreciated it.—D., *Deal*.

ALEXANDRA PALACE GREAT INTERNATIONAL FRUIT SHOW.

13TH, 14TH, AND 15TH SEPTEMBER.

THE liberal prizes offered by the lessees of the Alexandra Palace for fruit, vegetables, cut flowers, and table decorations brought together a very good display—a far better display than could have been expected from the general scarceness of outdoor fruit this season. The productions sent completely filled the large centre hall. Grapes were exceptionally good and shown in large numbers, no less than twenty classes being set apart for them. Peaches and Nectarines were very good, but perhaps not so extensively shown as in some previous years, and these same remarks will apply to most of the other sections of fruit classes. Dahlias were most extensively shown and in most excellent trim, as also were Asters, while the cut blooms of Roses—which came from Messrs. Paul & Son, Messrs. Cranston & Co., and several other exhibitors—were in splendid condition, and formed a very attractive addition to the Exhibition. Vegetables and salad were also shown in large numbers and in splendid condition.

Following in the order of the schedule Class I is for collection of sixteen sorts of fruits—not more than four sorts of Grapes, two sorts of Pines, and two sorts of Melons, for which the first prize is £16. This brought three remarkable even collections, and Mr. Coleman, gardener to Earl Somers, Eastnor Castle, was awarded the first prize for first-rate dishes of Muscat of Alexandria, Black Hamburg, Lady Downe's, and Madresfield Court Grapes, Pine Apple and Oldenburg Nectarines, Violette Hâtive and Early Crawford Peaches (very fine), Golden Gem and Eastnor Castle Melons, fine fruits of Smooth Cayenne and Black Jamaica Pines, large Brown Turkey Figs, Green Gage Plum, Pitmaston, Duchesse d'Angoulême Pears, and Morello Cherries. Mr. Thos. Bannerman was placed second with a very fine collection, and Mr. J. H. Goodacre, Elvaston Castle, Derby, third with a very smart and excellent lot. In the class for twelve sorts exclusive of Pines there were only two competitors. Mr. Neighbour, gardener to G. Wythes, Esq., Bickley, Kent, was first with very fair examples of Foster's Seedling, Black Hamburg, and Muscat of Alexandria Grapes, White Magnum Bonum and Victoria Plums, Violette Hâtive and Bellegarde Peaches, Brown Turkey Figs, Pitmaston Orange Nectarines, a Scarlet-flesh Melon, Jargonelle Pears, and White Currants. Mr. Rushmore, gardener to Sir C. R. Rowley, Bart., Colchester, was placed second with very good examples. For twelve sorts of fruits exclusive of Pines and Grapes Mr. Cox, gardener to Lord Beauchamp, Madresfield Court, and Mr. Thos. Crane, gardener to the Rev. L. Deedes, Bramfield Rectory, Hertford, were first and second respectively. Mr. Cox's collection contained good examples of Violette Hâtive and Crawford's Early Peaches, Goliath and Green Gage Plums, Irish Peach Apple, Jargonelle Pears, Warrington Gooseberries, Morello Cherries, Oldenburg and Downton Nectarines.

PINES.—Three classes for Pines were fairly represented, and the two best Smooth Cayennes came from Mr. Ross, gardener to C. Eyre, Esq., Newbury; Mr. W. Toomer, gardener to W. Knowles, Esq., Streatham, being placed next in order of merit; and the best pair of Queens, very even and good fruit, came from Mr. J. Churchfield, gardener to H. Littleton, Esq., Westwood House, Sydenham; while Mr. Toomer and Mr. Webb were placed

second and third respectively, and for two of any other kind Mr. Coleman was awarded the second prize.

GRAPES.—The first prize for eight varieties, one bunch of each, went to Messrs. Lane & Sons, Berkhamstead, for splendidly finished bunches of Gros Colman, Bowood Muscat, Black Hamburg, Muscat of Alexandria, Muscat Hamburg, Pearson's new Golden Queen, Alicante, and Trebbiano. Mr. W. Wildsmith, gardener to Lord Eversfield, Heckfield Place, winning second honours with bunches somewhat smaller and not quite so well coloured as the first-prize collection. Seven good collections were staged in the class for four varieties. Mr. Coleman was awarded the first prize for Madresfield Court, Black Hamburg, Lady Downe's, and Muscat of Alexandria, all finished in his well-known style. Mr. Bannerman came second with good examples of Alicante, Gros Colman, Trebbiano, and Black Hamburg. Mr. T. Coomber, gardener to Allan Rolls, Esq., Monmouth, third. In the class for three bunches of Black Hamburgs there were nine competitors, Messrs. Coleman, Coomber, Bannerman, and Edwards sharing the honours in the order named. Buckland Sweetwater was represented by five competitors, and the best came from Mr. J. Bain, gardener to Sir C. R. Boughton, Downton Hall, Salop; the next best from Mr. Miles, gardener to Lord Carlington, Wycombe Abbey; the third prize going to Messrs. Lane & Son. For three bunches of Madresfield Court, Mr. J. W. Chard, Salisbury; Mr. C. Tyler, gardener to R. Gosling, Esq., Hassobury; and Mr. Toomer, were placed first, second, and third respectively. Seven collections of Black Alicante were staged, and Mr. J. Freeman, Beechwood Park, Dunstable, was placed first with remarkably well-finished bunches; Mr. Peed, Roupell Park Nurseries, being a very good second; Messrs. Lane & Son, third; and an extra prize awarded to Mr. Goodacre. Lady Downe's was also well represented, and the best bunches came from Mr. Wright, Thurleston Lodge, Ipswich; and from Mr. Tyler, and Mr. Reeves, Grass Farm, Finchley, who were placed first, second, and third respectively, and an extra prize being awarded to Mr. Bannerman. Muscat of Alexandria was also extensively shown, and Mr. Coleman was again to the fore with three of the best bunches in the Exhibition, followed by Messrs. Lane & Son who were placed second, and third went to Mr. Wattam, gardener to A. H. Longman, Esq., Hemel Hempstead. Mr. Tyler was awarded an extra. For a single bunch of Black Hamburg Mr. Wildsmith was awarded the first prize for a splendid bunch, both for size of berry and an intense black colour. Mr. Cooper, gardener to M. Yeatman, Esq., was placed second, the third prize being withheld. Mr. Taylor, gardener to J. Johnstone, Esq., Hampstead, Mr. Wildsmith, and Mr. Cooper were placed in the order named for one bunch of Foster's Seedling. The first prize for a bunch of Madresfield Court was awarded to Mr. Peed, and the second prize to Mr. Cox, whose bunch was by far the largest but inferior in point of colour. For Black Alicante Mr. Peed was again first and Mr. Wildsmith second; and for Lady Downe's the first prize was withheld, the second prize going to Mr. Cooper.

For the finest-flavoured black Grapes fourteen collections were staged. Mr. Bannerman was awarded the first prize; Mr. Lane, gardener to Major-General Pfyche, the second; and Mr. Wildsmith the third; and for the best flavoured white Grapes Messrs. Coleman, Bannerman, and Bashford were placed first, second, and third respectively. Mr. Peed took the first prize for the heaviest bunch of Grapes (black) with Barbarossa, 5½ lbs.; Mr. Wildsmith second with a bunch 5 lbs. 2 ozs.; and the third prize to Mr. Coleman. For the heaviest bunch (white) the first prize was withheld. Mr. Wildsmith being placed second with White Nice, weight 6 lbs. 14 ozs.; and Mr. Peed third with Trebbiano, weight 3 lbs. 12 ozs. There was a keen competition in the two classes for baskets of Grapes not to exceed 12 lbs., Mr. Coleman winning the first prize in both classes with Black Hamburg and Muscat of Alexandria, which were grand; and Messrs. P. S. Kay, Finchley, was awarded second for blacks and third for whites, and Mr. Thomas was placed third with Black Hamburg and second for Muscats.

In the class for twelve Peaches there were eight competitors, and the best was a dish of Prince of Wales from Messrs. Haycock, Barham Court, Maidstone. Mr. Jones, Frogmore, took the second prize with Barrington Peach, and the third was awarded to Mr. J. Maher, gardener to C. Allhusen, Esq., Stoke Court, Slough, for Crawford's Early. Mr. Coomber was placed first with Royal George out of eleven exhibits for six Peaches, Mr. H. J. Clayton second with Late Admirable, and Mr. J. Seymour third with Bellegarde. Mr. Coomber, Mr. Haycock, and Mr. Seymour were placed in the order named for twelve Nectarines, the first prize being awarded to a dish of Pitmaston Orange; and in the corresponding class for six Mr. Coleman was placed first, Mr. Green second, and Mr. Crane third.

Figs were both plentiful and good. Messrs. Chisholm, Miller, and Coleman were placed in the order named.

The best Jefferson's Plum came from Mr. Clayton; the second from Mr. Pragnell, gardener to D. W. Digby, Esq., Sherborne Castle; the third from Mr. Murrell, gardener to A. R. Allerton,

Esq., Colemans, Essex. Mr. Murrell also exhibited the bese Kirke's, and Mr. Haycock gained the second place. For twelve Green Gages Mr. J. Fry, gardener to L. J. Baker, Esq., Haydon Hall, Pinner, was first; Mr. Cox second, and Mr. Neighbour third. For twelve of any other sort Mr. Haycock took the first place with Transparent Gage, Mr. Fry second with Belgian Purple, and Mr. Neighbour third with White Magnum Bonum.

PEARS.—The class for twelve sorts of Pears, two of each, were represented by no less than fourteen entries containing most of the popular kinds, and as they could be shown either ripe or unripe they were not so attractive as they would have been could they all have been shown ripe. Mr. Haycock was awarded the first prize with a very good lot. Mr. Fowler, gardener to Sir H. Mildmay, Bart., Dogmersfield, second; and Mr. Holder, gardener to W. Balston, Esq., Maidstone, third. Extra, Mr. T. Jones, Frogmore. Messrs. Coleman, Haycock, and Harris were first, second, and third respectively for Pears fit for table, all winning with Jargonelle. The best Williams' Bon Chrétien came from Messrs. Holder, Jones, and Haycock in the order named; and the six heaviest Pears came from Mr. Holder (Grosse Calebasse), weight 6 lbs. 7 ozs. Mr. Bromfield was second with Beurré Clairgean, 5 lbs. 2 ozs.

DESSERT APPLES contained eighteen collections. Mr. Haycock was placed first, Mr. Goldsmith second, and Mr. Holder third; and for baking Apples there were twenty-five competitors. Mr. Goldsmith, gardener to H. T. Lambert, Esq., Bletchingley, was first, Mr. Haycock second, and Mr. Holder third. For twelve dessert Apples, three of each sort, Mr. Haycock was again first and Mr. Holder second. Strange to say there was no competition for the six heaviest Apples.

Mr. W. Holder showed the best green-flesh Melon, Bromham Hall, and Mr. J. Bain the best scarlet-flesh, Reid's Scarlet. The competition was strong in both classes.

A portion of the schedule was set apart for foreign exhibitors, including the Channel Islands. This is a very good arrangement, and affords our home growers a better chance of competing on fairer terms. The whole of the classes were well represented, and Messrs. F. Le Suer and J. and P. V. Pluck carried off the lion's share of the prizes.

VEGETABLES were shown both numerous and in excellent condition. There were seven collections of sixteen sorts, and the first prize was awarded to Mr. Pragnell, who had well-grown examples of Student Parsnip, excellent Cauliflowers, Early Nantes Carrot, Potato Model, Ne Plus Ultra Pea, Sutton's New Improved Garden White Turnip (very good), Sherborne Improved Onion, Celery, Vegetable Marrow, Cardoons, Cretan Leek, a fine brace of Tender-and-True Cucumber, Dwarf and Scarlet Runner Beans, Tomatoes, and some very fine Veitch's Improved Beet. Mr. Arkell, gardener to A. J. Skinner, Esq., Cheltenham, was placed second, and Mr. Miles third. Mr. Miles exhibited a remarkably excellent collection, which we wonder was not placed second. An extra prize was awarded to Mr. John Hepper. A capital lot of produce was also shown by nine competitors. In the class for six dishes Mr. W. Iggulden, gardener to R. B. Wingfield-Baker, Esq., Romford, was first, and Mr. Cox and Messrs. Smith & Son second and third respectively. Collections of salads were shown by Mr. Hepper, Mr. Pragnell, and Messrs. Smith & Son, who were placed in the order named.

Mr. W. Soder, gardener to O. Hanbury, Esq., Brentwood, was placed first for a table completely laid for ten persons, displaying fruit and flowers set forth to the best advantage. Mr. J. W. Chard, Salisbury, gained the second place, and Messrs. Dick Radclyffe & Co. the third. Miss Stuart, Seven Sisters Road, Holloway, had the best wedding bouquet, and Messrs. Gilbert and Son and Mr. G. Thomas were placed second and third respectively.

DAHLIAS.—In the class for forty-eight varieties Mr. Keynes, nurseryman, Salisbury, was first with grand blooms of Bessie Ford, Charles Wyatt, Miss Large, Flag of Truce, Ethel Newcome, Egyptian Prince, George Goodhall, John Bennett, Lady Gladys Herbert, Queen of York, Leah, Marchioness of Lorne, Princess of Prussia, Vice-President, Willie Eckford, James Service, Mrs. Henshaw, Ovid, Prince Arthur, Mrs. C. Kimberley, Baron Taunton, Royal Queen, Henry Bond, Cremorne, Hon. Sidney Herbert, Picotee Alexander Cramond, Mrs. J. Downie, J. N. Keynes, Mrs. Boston, James Cocker, Mrs. Harris, William Lucas, Louisa Neate, King of Primroses, John Standish, Thomas Goodman, and one or two others. Mr. S. Dobree, The Priory, Wellington, was placed second with a very fine collection, and Messrs. Rawlings, Bros., Old Church, Romford, third. In the class for twenty-four varieties, amateurs, the prizes were awarded to Messrs. Smith, Glasscock, and Quennell in the order named. Asters were well represented by Messrs. John & Lewis Morgan, Mr. R. Petfield, and Messrs. Saltmarsh & Sons.

Miscellaneous collections were numerous shown, and several of the most meritorious received extra prizes. To Messrs. Lane and Son for pot Vines; to Messrs. Paul & Son, Cheshunt, for a collection of forty pyramid Apple trees. This was indeed an interesting collection, and contained amongst others Cockle's Pippin, Claygate Pearmain, Old Golden Reinette, Manks Cod-

lin, Cellini Pippin, Wellington, Lamb Abbey Pearmain, Hawthornden, Yellow Ingestrie, Old Golden Pippin, Small's Admirable, Cox's Orange Pippin, King of the Pippins, Hereford Pearmain, Lord Nelson, and Cheshunt Pippin; and extra prizes were also awarded to Messrs. Paul & Son for a collection of eighty dishes of Apples and several boxes of cut Roses in good condition. Mr. Paul set up distinct boxes of Sénateur Vaisse, Alfred Colomb, and Baroness Rothschild. Messrs. Cranston and Co., Hereford, sent fourteen boxes of Roses, which included numerous varieties, for which an extra prize was worthily awarded. Mr. W. Paul of Waltham and Mr. W. Corp of Oxford were also awarded extra prizes for cut blooms of Roses. Mr. Jones, Her Majesty's gardener, Frogmore, contributed an extensive collection of Apples and Pears, for which an extra prize was awarded; also to Mr. Turner for a collection of Lilium auratum. Certificates of merit were awarded to Mr. Keynes for seedling Dahlias Maid of Athens, Bessie Ford, and Louisa Neate; and to Mr. Turner for Charles Lidgeard and Lady Golightly; to Messrs. Rawlings, Bros., for James Willing; and to Messrs. J. & P. Harris for Dahlia Constance. The arrangements of the Show were most excellent, and reflect much credit on Mr. McKenzie, and we also hope the lessees received that encouragement they deserved.

NOTES AND GLEANINGS.

THE CONFERENCE of the CRYPTOGRAMIC SOCIETY of SCOTLAND will be held at Dunkeld on October 17th, 18th, and 19th. All Fellows of the Society are requested to endeavour to attend the Conference; other botanists are cordially invited to attend. Fellows and others who purpose coming will oblige by communicating with the Secretary. The Council hopes that all Fellows who can will furnish papers and communications, to be read at the business meeting. The Show will be restricted to specimens from the district, but novelties from other districts will be very acceptable. The Society is now prepared to issue a First Century of "Fungi Scotici Exsiccati," which will contain many of the new species and rarities recently discovered. The subscription price is £1 1s.

— WE have received from Messrs. Rutley & Silverlock, of the Strand, a cake of "SOAP" which is made from the seed of the Tea plant, and which is said to be efficacious in destroying worms in lawns. It is much used in China for this purpose, and if it is found to be equally serviceable in this country Messrs. Rutley & Silverlock will have conferred a benefit on those who are careful to have a clean lawn.

— VASES and dinner ornaments may be very prettily filled with leaves properly preserved. Brackets may be made to resemble carving, and also picture frames. The bright tints of autumnal leaves are excellent for the purpose. Gather a good assortment, which may comprise every tint from crimson to scarlet, from scarlet to yellow, and from yellow to green. The red Beech and the Sumach are very useful, so are the Oak and Ferns. Smooth every leaf on the wrong side with a hot iron, holding it down a minute or two. Any leaves that are not flat must be soaked in water first. Then oil them over on the right side. Next, take a number of fine wire stems, and fix every leaf to a stem. Lay the leaf over the wire, which should extend the entire length of the leaf, to support it. The leaf is attached by its stalk to the artificial stem. Use the fine green-covered reel wire necessary in wax-flower-making for this. Afterwards cover the stems with green tissue paper or brown Berlin wool, and join them together in sprays. The individual leaves on each spray must be of the same kind and colour. Afterwards mix and arrange the sprays according to taste. Oak leaves and acorns gummed on a cardboard frame make good brackets, boxes, and picture-frames. Acorns and other berries used in this way ought first to be cut in half.—(Cassell's Household Guide.)

— HAVING received a note asking for some poetic addition suitable for a young gardener's epitaph, we referred to a little volume entitled "EPIGRAMS AND EPIGRAPHS," by the author of "Proverbial Folk-lore," and we selected from it the following:—

"He died young, and thus as oft-times seen,
The fruit God loves He's pleased to pluck while green."

The volume contains a good collection and well arranged.

— THE CHILI PINE AS A FOOD PLANT.—The beautiful Conifer (*Araucaria imbricata*) is looked upon as a fruit tree in its native country, Chili and Araucaria. The Indians and other inhabitants of those countries eat its seeds raw, roasted, and boiled. They are said to be very nutritious; about two hundred form a good meal for an adult. One seed-cone contains from two hundred to three hundred seeds, and every tree

bears many such cones, which, when they have arrived at maturity, drop to the ground. The seeds lie in such great numbers on the ground that only a part of them are collected. The Indians have also a way of making a kind of brandy from these seeds.

THE "Journal of Forestry" gives the following enumeration of remarkable WALNUT TREES:—A Walnut tree at Gordon Castle, Banffshire, stands 66 feet high and 11 feet in girth at 3 feet from the ground; and at Altyre, Morayshire, there is one 62 feet high, with a trunk 4 feet in diameter. At Blair Drummond, Perthshire, there is one 75 feet high, and 13 feet 7 inches in girth at 2 feet up; and one of the finest in Scotland is at Eccles, Dumfriesshire, 63 feet high, girth at base 22 feet, and at 12 feet up 13 feet girth. In England there are many fine old Walnut trees of which there is no record. There is a fine one at Rufford Abbey, Notts, the butt of which, although only 4 feet long, girths 21 feet 10 inches at 2 feet up. Another particularly remarkable tree, which grows at Downlands, Hants, measures 16 feet in girth, and contains 223 cubic feet of timber. The above are but pigmies in comparison with the prodigious size and great age which the Walnut tree attains in Eastern Europe. In the Baider Valley, near Balacalava, in the Crimea, grows a Walnut tree at least 1000 years old, which yields annually from 80,000 to 100,000 nuts, and belongs to five Tartar families, who share its produce equally. Scammozzi, an Italian architect, mentions having seen at St. Nicholas, in Lorraine, a single plank of the wood of the Walnut 25 feet wide, upon which the Emperor Frederick III. had given a sumptuous banquet.

ZONAL PELARGONIUMS AT PUTNEY.

WHEN we visited Mr. Roser and saw the masterly examples of Geraniums grown by him, and heard of the praises bestowed on several varieties of Mr. George's raising, we felt somewhat anxious to pay a visit to Mr. George at Putney, and see them growing at their own home. A rich treat was in store for us. In a three-quarter span house from 20 to 30 feet long there were hundreds of plants growing in 6-inch pots, the majority of the varieties being Mr. George's own seedlings, the whole of which were in full bloom (Zonals and Hybrid Nosegays), with flowers of various shades of colour, and trusses like Hydrangeas. We measured one of The Moor, a deep rich crimson flower, and it was just 11 inches over—that is, measuring from the lowermost petal on the one side to the same on the other.

Mr. George had a few very promising seedlings, additions to those already sent out by him, in flower at the time of our visit; one was a zonal flower of a distinct crimson scarlet, the flower perfect in shape and a large truss. The raiser thinks very highly of it, says it far surpasses anything he has ever produced before. It is to be named General Grant. There were also other promising seedlings, especially a deep orange scarlet Hybrid Nosegay. This was not named, but we understood it would be sent out along with General Grant. Conspicuous amongst the quantity of bloom we noted A. F. Barron, Par Excellence, Ivanhoe, Rose Unique, Royalist, Seraph, Salamander, Progress, Sir Garnet Wolseley, Mrs. J. George, Enchantress, Chancellor, Cromwell, The Shah, H. M. Stanley, and Negro Boy, all Mr. George's seedlings. There were numerous other varieties, for the house was one mass of colours, verily maintaining the fact that no other flowers but Zonal Pelargoniums could make such a show in such small space, and remain in bloom for so long—May to October. Mr. George perpetuates his stock in the manner described by Mr. Roser, and simply blooms them in 48 and 32-size pots. In the distance we saw some beds of H. M. Stanley, which is without doubt one of the finest bedding Geraniums we have. The numerous varieties sent out by him, and the excellent qualities they possess both in size of pip and truss as well as finish of flower, must rank Mr. George as one of the most successful raisers of both Zonal and Hybrid Nosegay Pelargoniums of the day.—AN EXHIBITOR.

THE APPLE ELECTION.

A FORTNIGHT from the publication of this letter in your Journal I intend closing the Apple election; will you therefore kindly use your editorial influence to induce Apple growers to forward more lists? The result will be published at a time when growers will be able to look over their own grounds and compare the results of the election with their own experience.

It is also a year to note the bearing properties of the different kinds, so as to know what to plant and what to avoid. After the election I shall be pleased to compare notes with other growers through the medium of your Journal.—LEWIS A. KILLICK, *Mount Pleasant, Langley, Maidstone.*

[We commend to the notice of our readers Mr. Killick's excellent suggestion for them to note the bearing properties of the different kinds. This will afford very valuable information in a year like the present, when so great a failure of the fruit crops has taken place. We may remind growers that the election is for fifteen dessert and the same number of kitchen Apples.—EDS. J. OF H.]

ROSE SHOWS.

HAVE the Roses shown at the various shows this year been up to the mark? Have they been up to the average? I fancy this may seem a startling question to some, but I do not know that there is any harm in putting it. If I state my own opinion in the most prosaic manner possible, I should simply answer the above question with a direct negative. I do not think that any stands shown by nurserymen or amateurs have been equal to what I remember five years ago. But more particularly do I think that this has been the case with the great nurserymen. It may be that my ideas have advanced, that what seemed to me magnificent five years ago now seems merely an ordinary stand, but somehow I do not think it is so. Mr. George Paul's stand at the Royal Horticultural Gardens the last time that that Society had a Rose show in a tent, and Mr. Baker's stands the year that he swept the board at Exeter, Crystal Palace, and Hereford, have in my opinion never been equalled. I was not at the Alexandra nor at Hereford, and I believe that the former show was one of the, if not the, best of the year; but I was at all the others, and I can confidently say, that with certain exceptions hereafter named, I saw no astonishingly good bloom shown. The exceptions were generally among the amateurs, although Mr. Curtis at Torquay certainly showed a bloom of Prince Camille de Rohan which I never saw equalled. Mr. Baker's bloom of Marie Van Houtte shown at Exeter was, in my opinion, the bloom of the season; and next to it I should place Mr. Curtis's Camille de Rohan, next to that the bloom of Marquise de Mortemart shown by Mr. Jowitt at Torquay.

Throughout the year the Teas have come to the front remarkably well. Mr. Cant's stands were always remarkable for good Teas, but this year he surpassed himself; but perhaps the best of the year were those shown by Mr. Mitchell of Pitt-down at the Crystal Palace. This year I have never known some of the Teas bloom so well before in the autumn, particularly Marie Van Houtte; indeed this Rose with me never does so well in summer as in the autumn.

With regard to a question asked by my friend "O. P. P.," as to the cultivation of these charming flowers in the north, I would recommend him to take up his Teas every autumn and plant them in pots, and take them into a conservatory till May, then plant them out again; or if he has not room for this, I would still advise him to lift the plants and place them in some sheltered corner, and during the frosts cover them over with mats. Plant them out again the next spring. It is almost hopeless to try and grow tender Teas in the north without protection.—WYLD SAVAGE.

RUFFORD ABBEY,

THE RESIDENCE OF HENRY SAVILLE, ESQ.

RUFFORD is a place of considerable antiquity, and was formerly called Rugford or Ramford. It is bounded on the north by Ollerton and Edwinstowe, on the west by the manor of Clipstone, and on the south by the Hundred of Bassetlaw. It is one of those places somewhat difficult of access, for it is nine miles from Tuxford (the nearest railway station) and eleven from Mansfield. The little market town of Ollerton, ten miles from Rufford, is pleasantly situated near the confluence of the Mann and the Rainworth water, on the Work-sop and Newark road.

It is always interesting to stroll through a country churchyard and read some of the inscriptions on the ancient stones; and on the church bell at Ollerton we meet with the following:—

"I to the church the living call,
And to the grave do summon all."

But the most singular epitaph is on the tomb of Francis

Thompson, who was for many years butler at Rufford Abbey. It runs as follows:—

"Beneath the droppings of this spout
There lies the body once so stout
Of Francis Thompson.
A soul this carcase once possess'd
Which for its virtues was carress'd
By all who knew the owner best.
The Rufford records can declare
His actions, who for seventy years
Both drew and drank its potent beer.
Fame mentions not in all that time
In this great butler the least crime
To stain his reputation.
To Envy's self we now appeal,
If aught of fault she can reveal,
To make her declaration.
Here rest, good shade, nor hell nor vermin fear.
Thy virtues guard thy soul, thy body good strong beer."
He died July 6th, 1739.

The principal entrance to the Abbey and grounds is from the Ollerton road through a noble pair of iron gates erected in excellent taste by the late Earl of Scarborough. On the opposite side the road there is a neat lodge surrounded with a nice flower garden, which at once impresses the visitor with a feeling of grandeur. From the entrance gates to the Abbey there is a fine avenue of Limes—"tall ancestral trees," which have weathered the storm of many a winter and stand dignified in their leafy grandeur. We now reach the Abbey, which presents an air of comfort seldom to be met with, and this, rather than structural excellence, appears to have been the prevailing motive of those who have converted an old monastic residence into a country gentleman's seat. It is difficult at this time to say how much of the present building is a remnant of the original Abbey. The architecture and masonry of the south end of the house are, at any rate, as old as the days of the first lay possessor—the Earl of Shrewsbury, and probably much older, but the interior arrangements have been so far altered from time to time as to leave little trace of the plan of the original building. Two important features, however, remain much as they were from the first—viz., the spacious hall and the crypt below it; the former was restored by the late Earl of Scarborough and fitted up in a manner suitable to its original intention and design; the latter was at the same time brought to light by the removal of a chaos of subterranean rubbish, and now, as well as being converted into useful purposes, it attracts the attention of archaeologists as a perfect specimen of a crypt of considerable antiquity.

The entrance to the Abbey is plain and unpretentious, and in character with the other architectural arrangements of the mansion. Bearing to the left we pass along a broad terrace walk. In the distance there is the Wilderness with its pleasant drives and its umbrageous walks. From the north-east corner of the Abbey we have a grand view of the Beech avenue, that extends across the park and is terminated by a pair of iron gates. South-east of the Abbey in the park there is an extensive lake, dotted here and there with islands, with an irregular and wooded margin, so essential in water scenery. This forms an important feature in the landscape. The pleasure grounds are separated from the park by a sunk fence, and from various parts of the Abbey the scenery is of a most imposing character. In the pleasure grounds I noticed some noble trees both deciduous and evergreen, including Cedars, Tulip Trees, fine Hollies resembling forest trees; and just on the border of the park there was at right angles to the Abbey a fine pair of variegated Sycamores, and between these a Purple Beech, the foliage of which contrasted most beautifully with the elegant variegation of the Sycamores. On the flights of steps leading to the drawing room there were some tastefully arranged vases filled with Geraniums and other bright-blooming plants, which contrasted favourably with the emerald green of the lawns and the diversified foliage of the shrubs and trees.

We next reach the rosery. Here the beds are formed into diamonds and half-diamonds, with narrow walks running between. The first display of bloom was over, but there was the promise of plenty of Roses for the autumn. Following Mr. Doe, the gardener, we pass along a broad terrace walk that skirts the park, and here I may just add that the latter contains upwards of 500 acres, and is well stocked with deer. Nature has done much for the park in its undulations, and it is also well wooded. On the right of this walk are the kitchen gardens, and at its termination is the flower garden. This covers nearly two acres, and is situated south of the kitchen garden.

It is bounded on the north side by the garden wall, 120 yards long and 10 feet high; on the east and north side by a Portugal Laurel hedge 9 feet high and 6 feet through at the base; the west side is open to the park. There is a border in front of the garden wall 15 feet wide planted in the ribbon style within 2 feet of the wall. Parallel with this border there is a broad gravel walk 9 feet wide, and then another border 12 feet wide planted in the same style as the other. On the border next the wall there were fourteen rows of plants as follows:—Beginning at the row next the walk, the first was *Cerastium tomentosum*; second, *Viola Perfection*; third, *Pansy Cremorne*, yellow; fourth, *Geranium Harry Hieover*; fifth, *Geranium Flower of Spring*; sixth, *Ageratum Imperial Dwarf*; seventh, *Geranium Christine*; eighth, *Geranium Bijou*; ninth, *Dell's Crimson Beet*; tenth, *Cineraria maritima*; eleventh, *Geranium Tom Thumb*; twelfth, *Geranium Stella*; thirteenth, *Perilla*; fourteenth, a very dark *Fuchsia*, which stands the winter and blooms during summer with great freedom. The first six rows of the border on the opposite side of the walk were planted just the same as the first six rows of the other border, and then beginning at the seventh row it was *Geranium Crystal Palace Gem*; eighth, *Dell's Crimson Beet*; ninth, *Cineraria maritima*; tenth, *Geranium Tom Thumb*; eleventh, *Geranium Beauty of Calderdale*; twelfth, *Geranium Harry Hieover*; thirteenth, *Pansy Rufford Pride*; fourteenth, *Alternanthera amœna*; fifteenth, *Cerastium tomentosum*. These beds looked exceedingly rich, and notwithstanding the constant downpour of rain for the previous fortnight the flowers were most brilliant. Besides these two broad borders there were three other sets of beds, all arranged in diamonds and half-diamonds. I did not measure the exact width of the beds, but each set would be about 15 feet wide. First there was a row of diamond beds down the centre, with gravel walks down each side and half-diamonds between the gravel and the grass. These beds extended the whole length of the garden, 120 yards, and were repeated three times over, with a narrow strip of grass running between each set of beds. I was not particularly struck with the beauty of the design, for so many beds all of the same size and shape, and all bounded with straight lines of the same length, appeared monotonous and oppressive. However, the planting was made the most of, and reflected great credit on Mr. Doe the head gardener. The ordinary run of bedding plants was used, carpet bedding not being attempted in this garden. *Coleuses* and *Iresines* were most effective as foliage plants, and *Pansies* and *Violas* as flowering plants. The splendid masses of *Violas* and *Pansies* at once stamp these plants as being invaluable for the summer decoration of the flower garden. There are no plants that produce the same number of flowers on the same area of foliage; they are also neat and compact in habit, dwarf and very hardy, and a large number of plants can be wintered in a small space. They are easily propagated, come into bloom with the first indications of spring, and stay with us till the flower garden is littered with withered foliage in the autumn. A season like the present—at least like what we have experienced down here in the midlands, where we have had more or less of rain most days lately, and sometimes our flower gardens submerged, *Geraniums*, *Petunias*, *Verbenas*, and the like have either presented a woe-begone appearance or run away to foliage; but the excessive rain not only suits *Pansies* and *Violas*, but increases their beauty. I have no doubt but when these bedding *Pansies* and *Violas* are better known they will be grown as extensively as the *Golden Feather Pyrethrum* and cultivated in every garden; and then the colours are so good and varied, and such a continuity of bloom—in fact, a perfect sheet of bloom from April to the beginning of winter. And there is yet another feature, which must be a very important one, especially with those having very small means for wintering tender plants—there is no glass structure required, no propagating pit, no fuel, no damping and shading, no covering or uncovering, are needed with them during winter; only a cold frame or turf pit, and in the absence of these they may be wintered at the foot of a south wall. The plants have no need to be disfigured as soon as they begin to bloom, which is the case just now with the *Geraniums*, and they require no special care after they are planted in their blooming quarters. At a place like Rufford, where no attempt is made at spring gardening, they can be planted out by the end of March, when they grow with greater vigour and are not affected with dry hot weather, which sets in later in the spring. The two *Pansies* grown at Rufford are *Cremorne*, yellow, and *Rufford Pride*, both raised by Mr. Holah some years ago when he was gardener there. I do not know whether

they are in the trade or not, but certainly they are sufficient to immortalise Mr. Holah's name. About thirty thousand plants were used to fill up the beds in this garden alone. Beyond the flower beds there was a Rose bed, perhaps 8 feet wide, and then a broad pure stream of water crossed by a wooden bridge, and on the other side the stream a bank of Rhododendrons the whole length of the garden. Down the centre there was a cross walk leading from the kitchen garden, on either side of which there were some splendid specimens of Pampas Grass (*Gynerium argenteum*), throwing up scores of spikes of bloom.

We must now leave this floral retreat and enter the more useful department of this demesne, the kitchen gardens; for as the late Dr. Johnson once said, there was no flower in the garden equal to the Cauliflower, and there these were growing with the greatest luxuriance and freedom in sufficient quantity

to gratify the most extravagant epicure of this wholesome vegetable. The kitchen gardens occupy about three acres surrounded by well-built brick walls, and divided into three compartments. Having passed through the gates we will lead the reader along the centre path. This is skirted with broad ribbon borders, and these are again interspersed with standard Roses. The ribbon borders are backed with espalier Apple trees, which separate the flowers from the vegetables beyond. Near the margin of the walks that run right and left were rows of Gooseberries and Currants mostly in the bush form, excepting a few Gooseberries trained to wires. The walls were clothed with Cherries, Pears, Plums, and Apricots, and one wall with a south-east aspect was entirely devoted to Peaches, but they were nearly destroyed by the frosts of last May. In regard to the fruit crops there was of Pears about half a crop, of Apricots only moderate, Cherries good, Peaches on the open wall

Fig. 48.—RUFFORD ABBEY.

two, how these would be divided between a large party I do not know unless they agreed to quarter them; Apples excellent, Gooseberries and Currants good, Raspberries an average crop, and the Strawberries most abundant.

The vegetable crops were also of a very high quality, and in this department Mr. Doe's skill as a caterer for either Mr. or Mrs. Cook were especially predominant. The Potato crops were heavy, but the disease had set in with a terrible vengeance.

We now enter a range of vineries in three compartments, intended for late work. They had been planted some time before Mr. Doe took charge of the gardens, but as they are not quite satisfactory some alteration is intended to be made. Figs in pots were plentiful. In a large house in proximity to those last named the Vines were in good condition, the foliage healthy and clean, and the Grapes an excellent colour. Near this vinery there was a small enclosure bounded by an Elm and Holly hedge, which enclosed a very handsome geometric flower garden. All the beds were surrounded with Box edging, and the walks were of gravel. The planting was tastefully done; but as the rain came on heavily we were unable to take notes of the arrangements.

In another range of houses in three divisions, the first 45 feet long, was filled with stove plants entirely for the de-

coration of the Abbey on festive occasions. Many of the plants were in 5 and 6-inch pots, and included such things as: *Dracænas* of sorts, Palms, *Caladiums*, *Crotons*, *Marantas*, and a few Orchids. The second house, 30 feet long, was chiefly Ferns, and contained a nice selection of *Lomarias*, *Davallias*, and *Adiantums*, all grown for a specific purpose. The third house in this range was also for stove plants, and contained a similar stock of plants to No. 1 in the same range. On the roof was a fine *Stephanotis* planted out in a small border. In the front of these houses I noticed ranges of pits for Cucumbers, &c. In an adjoining vinery there were some capital pot Vines, but the permanent ones were to be uprooted and the house replanted immediately. From this vinery we enter a greenhouse, where the plants are all grown for house decoration. The most useful class of plants was a fine strain of *Celosia pyramidalis plumosa*. The plumes were of the richest tints, and formed a fine contrast with foliage and flowering plants.

Retracing our steps we reach another vinery, from which the fruit had all been gathered and the Vines going to rest. In the same range we pass into an early Peach house, the wood in good condition and giving promise of fruit another season. The next house was also for Peaches and Nectarines,

and here the fruit, which was partly gathered, was of very high quality. In the front of these houses there was another flower garden, which was well done and such as Mr. Doe had good reason to be proud of. I was informed that the number of plants required for the flower gardens, ribbon lines in the kitchen garden, and the decoration of the various lodges on the estates, was upwards of 45,000.

We now leave the kitchen gardens and just peep into the usual slip or enclosure at the outside. Here were other useful houses, chiefly employed for Melons and Cucumbers. Of the latter Tender-and-True was very good, but I could not see that it was much in advance of the old Telegraph. In cold pits there was a multitude of Primulas, Cinerarias, Mignonette, Sweet-scented Verbenas, and thousands of other useful plants in their season of bloom. Mr. Doe has scarcely been at Rufford a year, but considering the amount of his labour these extensive grounds were in excellent keeping.—Q. R.

THE POTATO CROP.

SPRING and early summer cold and wet, the frosts in not a few instances cutting-off to the ground the tender haulm of the early crops. Ours, however, from not being above ground escaped. Though late, never, perhaps, was the Potato crop looking so well as this season. The haulm though strong was remarkably sturdy, lacking the rankness prognosticating disease.

During the great promise of the Potato crop a bill passed the Legislature, an order in Council followed, with the concomitant notice papers posted in conspicuous places to prevent the introduction and spread of the American Potato bug or Colorado beetle, a very pretty insect judging from the illustration. I confess to having seen nothing in the figured creature, nor in the accounts given of it, to cause fear of its making any great havoc of the Potato crop in this country should we be so unfortunate as to receive a visitation of this kind from across the Atlantic. Our brethren in America will assuredly exterminate this obstacle to their progress, as they have done or are doing with the buffalo and Red Indian.

The Colorado beetle, forsooth, eat up the Potato crop of the English-speaking race! It is well, perhaps, to be armed against a threatened invasion, than which, perhaps, none are better prepared. Not a Colorado beetle or any other bug, not omitting a "bug-bear," which is often proved by invasion panics, can maintain a footing upon our treasured soil. Our feathered friends would make speedy work of the hated intruder, and our climate annihilate the remnants.

We beat the air in the vain endeavour to catch a feather, all the while unable to see a real evil, one we have tolerated in our midst for more than thirty years without an effort being made at riddance. Our learned societies have done nothing, our Legislature less. Private enterprise has shown at last the resting-spore of the Potato fungus, but notwithstanding all our knowledge of the parasite one of the most important of our food products is literally rotting before our eyes. The tops of the Potatoes are a spotted, blackened, leafless mass; from beneath the soil is emitted a nauseating smell, and nothing is done to stay the plague, which means a dear loaf if not calamity as disastrous as the Potato famine of 1845 and 1846 decimating the sister isle, and it may be this time both. Nothing so certain, as when the Saxon finds his industry will bring him but half a loaf, every sacrifice that can be made will be made to make it a full one where the means for doing so exist.

There is little reliance to be placed upon private effort in taking the needful precautions to avoid a national calamity. This is well understood in respect of the sanitary precautions requisite for securing the greatest possible freedom from disease in towns. Proper drainage, removal of nuisances, properly constructed dwellings, are insisted on as conducive to the health and well-being of the general community, and yet no one cares anything further about the loss of half or more of a staple article of food-producing crop than to keep aloof from insisting that preventive measures be taken to prevent its prevalence. The failure of the Potato crop wholly or in part is a national loss, the burden of which is borne in chief by the humbler classes. It may be urged that we know nothing for certain respecting the Potato murrain, therefore for the Legislature to interfere would be iniquitous intermeddling with individual effort. Many do not believe in vaccination as a preventive of small pox, and not a few agriculturists insist on there being some cattle slaughtered that are not affected with rinderpest, or would

have survived were they let live. It is not only difficult but absolutely impossible to satisfy everyone, but in case of a national calamity, as that of disease decimating the subject or diminishing its food products, the interference of the Legislature is clearly necessary to prevent by known preventives the loss of one as well as any other food product. In brief, the Legislature interferes in so many ways directly and indirectly with the liberty of the subject to abuse or injure himself that no apology is needed for its interference with horticulturists and agriculturists in the cultivation of Potatoes. Experiments should be instituted at the public expense with a view to finding a compound in which coated or immersed the sets infected with disease would be destroyed along with its parasite, thus preventing the planting of infected tubers. This would at least rid us of one form of the disease—viz., curl, one result of planting infected tubers, if not, indeed, it be not the means by which the spores of the fungus are reproduced, and carried by every breeze over a wide tract of country, waiting only for the atmosphere to produce a condition of the Potato foliage favourable to their development. If at this time (which is generally at the close of June with early crops, and a month later with winter-supply crops, that the plants infected with curl begin to collapse), a dressing of the antidote experiment may determine as most fatal to the spores of the fungus, were applied, the Potato crop might be saved or the ravages of the fungus considerably mitigated. Then, when the disease had unmistakably commenced its attack upon the haulm, and was descending or had descended to the tubers, there being no question as to the prevalence of murrain in the field or plot, the owner should be notified by a public functionary to have the haulm of the Potatoes pulled-up, and as pulled burnt.

In lifting the tubers it should be made imperative to separate the diseased from the undiseased tubers, not allowing the diseased to lie upon the ground, but be cleared off as promptly as the sound Potatoes; it being insisted on that no one shall offer for sale or sell any diseased tubers so far as is discernible by the naked eye, which shall apply to those sold for food, whilst those sold for seed must have been disinfected before delivery.

Fine, and it may be imprisonment, would be necessary to enforce the regulations that might be suggested by a Royal commission and be made law by the Legislature. Many will, of course, be adverse to interference in such matters by the Legislature, but most will agree in the importunity of the subject. The imperfection of our knowledge of the fungus is no excuse for our allowing the half or more of a valuable food product to be wasted by neglecting to enforce those preventives experiment has proved desirable.

The Potato crop promises to be one of the worst as regards disease we have experienced for many years. The late wet weather has had a most prejudicial effect upon the field crops—the haulm is fast becoming leafless, their stems blackened, whilst the effluvia emitted is convincing, if proof were needed, that the fell destroyer is at work upon the tubers.

In the garden the early crops were good but late. Not a diseased tuber was found in the Veitch's and Myatt's Ashleafs, they being good in crop and excellent in quality. Lapstone, very susceptible of disease, was sound up to the third week in August, when a few diseased tubers were lifted, after which the disease spread with amazing rapidity. Within a week fully two-thirds of the tubers of Snowflake were infected with disease, and scarce a sound one to be found of Early Market, which, though a good-quality Potato and producing a quantity of tubers, is oft too small in size. It will not be grown again. Rector of Woodstock is in the same plight as Snowflake. Bountiful, not many bad; and Early Vermont nothing to complain of, though the haulm of both are gone. Of Victoria scarce a sound tuber is to be found; and though the Regents are not as yet much infested, they are losing the leaves and the stalks are badly blackened. Not since the years 1845 and 1846 have I seen or heard of so bad an infection. I have omitted mention of many kinds, which though fancy kinds have scarce a place for consumption, they being of little value beyond swelling the lists, gaining no favour except in the raw state at exhibitions—fine to look at—great bulky fellows that have no admirers by consumers. If there is anything that deserves to be called a sham it is Potato exhibitions, outward appearance and size being the chief points of a show kind, whereas the tuber's value is dependant upon its cropping and quality. In the fields there is great and general prevalence of disease, the appearance is such as to leave little doubt of the crops being as disastrously affected as the garden crops.

I have nothing to say with a view to preserving the crops affected other than seconding the remarks of your able correspondents who have advised the taking-up of the crops upon the first appearance of the disease in the haulm, or, without waiting for the disease to manifest itself in the haulm, take up the crop when full-sized or so soon as the setting of the skins will allow. This is capital advice, but quite impracticable with rain every day for three weeks or a month at a stretch. To lift Potatoes with the soil little better than mud would be suicidal, but to remove the haulm is an operation that may be performed when the raising of the tubers from the wetness of the soil is impracticable, for there is great difference between lifting rods in a garden and acres in fields.

Nor will I dwell on the means to be adopted for the avoidance of the disease, such as keeping of the seed in sheds exposed to atmospheric influence, the planting of kinds only that arrive early at maturity, with the avoidance of fresh stimulating manures in contact with the sets at planting, and those artificial ones which induce to an increase of haulm, being equally silent of "salus," inasmuch as though I hear of its strengthening the haulm, and there being few tubers diseased in those dressed therewith as compared with those not dressed, but I do not see in this anything further than the increased vigour of the plant, which implies the disease to be of weakened constitutional origin, resulting of the plant's subjection to an excess of organic manures, or their application to this particular crop, out of all proportion to the inorganic elements present in the soil, and forming such important constituents in the structure and maintenance in health of vegetable life, which is supported by the unerring evidence of facts, as in most instances the disease is most virulent in alluvial deposits—soil full of humus, those containing much decomposing vegetable or animal manures. The first diseased plot of Potatoes I saw this year was on land taken in or enclosed from a moor as a cottager's Potato ground. The ground may have been under crop with Potatoes near on to a decade, certainly for more than seven years consecutively cropped with Potatoes. The soil on the moor surrounding is a black spongy peat about 9 inches deep, destitute of silicious matter, with an under strata of sandy alumina, and a subsoil of stiff clay. The soil immediately beneath the peat is largely impregnated with oxide of iron, indeed the whole subsoil is so strongly impregnated with iron that the springs give out the red oxide to the water. The very life of such soil for cultivation is to be found in applications of lime, especially magnesian; but no such application had been applied, only organic substances. There was no mistaking the disease in the plot had its origin in curl, the remains of the plants collapsing of curl being disposed irregularly through the plot, the haulms of the other plants fast falling a prey to the disease. This was at the middle of July, and at the end the kind infected—I took it for Mona's Pride—was a mass of putrefaction. This was fully a month before we noticed any traces of the disease, and we had it a full fortnight before it appeared in the fields. In one field I noticed a part of about two acres with the haulm blackened and leafless, whilst the other part was apparently unaffected; in a fortnight they were badly infected.

My opinion is that we do nothing but propagate the disease wholesale—fold our arms and despondingly watch the ravages of the murrain, instead of promptly setting to work upon its advent and promptly removing every vestige of the disease in the haulm; and if we persist in this the probability is that we allayed its ravages upon the present crop. Secure sets untainted with disease for planting, it being well known that unripened tubers were known to be a sure remedy for curl so far back as 1806, it being propounded by Mr. Thomas Dickson of Edinburgh, in which he was confirmed by Mr. Knight. There is one other point worth mentioning in respect of unripe tubers for planting—viz., the earlier ripening of the resulting crop.

I mention these subjects to show that we are at least less practical in dealing with the disease of 1845 than was the case at the commencement of the century with curl, and that the best known preventives are identical with those then put forth as a preventive of curl.—G. ABBEY.

CHESHUNT HYBRID ROSE.

I WOULD desire to second most thoroughly what my good friend Canon Hole has said in last week's Journal, and to say how gladly we all welcome Mr. Peach's again wielding his pen.

It is rather hard, however, to have to differ from him in so doing; but so valuable is Cheshunt Hybrid esteemed in the south-west of Scotland, that Mr. Mackenzie at Newton Stewart, who has grown it pegged-down, now purposes (so thoroughly is he satisfied with it) to make one large bed in a small garden of it. When I was there in July it was in great beauty.—D., Deal.

NEWCASTLE BOTANICAL AND HORTICULTURAL SOCIETY—AUTUMN SHOW.

SEPTEMBER 12TH AND 13TH.

VIGOROUS even in old age is the characteristic of the Newcastle Botanical and Horticultural Society. Entered as it has on its fifty-third year, it appears still young—is, indeed, growing not only rapidly but substantially. To what is to be attributed the sudden—for it is sudden—resuscitation of this Society, which at one time was in a comparatively decrepid state? It may be summed up, perhaps, in two words—discretion, enthusiasm. Without enthusiasm the labour that has been given would never have been forthcoming; without discretion that labour would not have resulted so satisfactorily. But who has possessed these important requisites? Well, the Committee are anxious to debit them to the Honorary Secretaries, Messrs. Taylor and French, while the Secretaries attribute the improved position to the working Committee, such "good men and true" as the veteran Garrett and his younger associates, Messrs. Edward Wilson, jun., William Dinning, Tranah, Plummer, jun., Adams, and others.

That is a good sign—the best evidence not only that all have worked, but that they have worked in unity and harmony. The real improvement, therefore, that has taken place is traced to four essentials—discretion, enthusiasm, unity, and harmony. They are worth mentioning, for with them any society may flourish, as far, at least, as it is possible to make it do so; without them no organisation can long remain healthy and prosperous.

But wherein has this Society rendered itself so especially remarkable? Let a few, a very few, facts answer the question. Less than a year ago its subscription income was £180, and its liabilities £200; now its subscription income is nearly or quite £2000. In numbers the members a year ago were less than four hundred, now they are nearly four thousand. Such results are emphatically worthy of record, and Messrs. Taylor and French (for while admitting the valuable services of every member of the directorate), the gentlemen named must have the honour which according to the most impartial estimate that can be formed is rightly their due.

But who are Messrs. Taylor and French? is a question that will very naturally force itself uppermost. Gardeners? No, not gardeners, yet without the aid of gardeners such results could not have been achieved. The practical knowledge of gardeners has been applied by gentlemen of position in the mercantile world, whose commercial training has proved its power, and whose business aptitude has achieved success. The manner in which they have worked is, perhaps, not so easily apprehended, but it may be stated that they have visited shows in other districts and noted points both to adopt and to avoid. They have examined the systems of procedure of other societies with the same object. They have proceeded on a liberal scale—that is, when they have decided on a course they have carried out their plan fully and well. They have advertised and circularised systematically, and have secured support both local and general. Let an instance of "circularising" be noticed, for there is no teaching so cogent as example. Leaflets we will call them, setting forth in concise terms the advantages of a horticultural society, have been distributed systematically. With each a printed and ready-addressed postcard has been sent, requiring only the name of the subscriber and the amount of subscription entering. These have been returned by hundreds, £40, indeed, having been received on the day previous to the Show (the 11th inst.), and £40 more on the day of the Show alone. Of course every facility has been given to induce membership, and the utmost liberality consistent with sound commercial principles has been exercised in the granting of privileges. The object, a wise one, is to place the Society on a sound basis financially, by seeking such an income from subscriptions that will render the Society independent of gate money—that is, that its existence shall not be at the mercy of that ever-impending contingency, a rainy day.

The response to the efforts made to secure support warranted the Committee in announcing three shows for the present year, offering prizes to the amount of nearly £600. The spring show in March was a gratifying success, the summer show in July is admitted to have been the greatest and the best ever held in Durham or Northumberland, and the autumn show held on the 12th and 13th inst. was an excellent one, such as to satisfy the promoters and to secure the approval and confidence of the public. As an instance of the extent of the public support accorded it may be mentioned that the Society has enrolled 170 Vice-Presidents, including eleven Mayors, and it has the

distinguished patronage of the whole of the aristocracy of the district.

The Exhibition was held in the Corn Market and in the Town Hall above it, two fine and well-lighted rooms, each about 250 feet long by 50 feet wide. The rooms were attractively decorated, and the tables for the fruit and flowers were covered with smooth white paper, which had a very clean and finished appearance, very different to the rough deal boards at Carlisle, which marred the effect of that great show. The plants and florists' flowers were arranged in the Corn Market, and the table decorations, bouquets, epergnes, &c., also the fruit, were displayed in the room above, and the effect produced was excellent. The following summary of the exhibits affords an idea of the extent of the Exhibition:—470 plants, 350 Dahlias, 324 Hollyhocks (blooms and spikes), 168 Gladioluses, 1294 cut blooms exclusive of the above, 4 decorated dinner tables, 60 epergnes and bouquets, &c., and 276 dishes of fruit. Owing to the comparatively limited space the plant classes were not numerous, and on the same account nurserymen's miscellaneous exhibitions could not be admitted. The specimen plants in flower were excellent considering the period of the year. The cut flowers were extensive and superior, the finest display of the kind we have seen this season; and the fruit was in considerable quantity, much of it being of capital quality. It is only necessary to notice a few of the leading collections and chief prizewinners.

PLANTS.—These were arranged on the floor of the Hall. The patrons' prize of £10 for six specimen plants in bloom was won by Mr. Tudgey, gardener to T. E. G. Williams, Esq., Henwick Grange, Worcester, with *Ixora Williamsii*, 4 feet in diameter and in excellent health and bloom; *Clerodendron Balfourianum*, still larger; *Erica Eweriana* *superba*, a splendid example, 5 feet in diameter and very fresh; *Allamanda nobilis*, very fine; *Anthurium Scherzerianum*, $\frac{1}{2}$ feet across, with thirty spathes; and *Ixora Dixiana*. These plants fully merited the premier position on account of their freshness and uniform good quality. Mr. Thos. A. Wilson, The Gardens, Normanby Hall, Middlesborough, had the second prize with a collection more unequal in size, some of the plants being very large, others comparatively small. The *Stephanotis* in this group was splendid; *Dipladenia Brearleyana* had thirty fine flowers, and *Erica orbata* *purpurea* was very good. Mr. Tudgey had the third prize, the rules of the Society permitting an exhibitor to take more than one prize in a class—a plan which is no longer necessary to ensure an exhibition at Newcastle. In the class for three plants in bloom Mr. Moulton, gardener to the Earl of Ravensworth, Ravensworth Castle, won with *Ixora javanica*, *Cassia corymbosa*, and *Erica retorta* *major*. The last-named specimen was the premier plant of the Exhibition, a grand example of culture 5 feet in diameter, and apparently faultless. Mr. J. Thompson, Ravenside, Fenham, had the remaining prizes, his noticeable plant being *Lapageria rosea*, 5 feet high by $3\frac{1}{2}$ feet in diameter, in admirable condition. Ornamental-foliaged plants, were not generally of such high excellence as the flowering specimens. Mr. Tudgey was the only exhibitor of six plants, and secured the Treasurer's prize with *Latania borbonica*, two *Cordylines*, two *Crotons*, and *Cycas revoluta*; and in the class for three plants Mr. A. Methven, Heathside, Gateshead, was first with a good *Croton variegatum*, a very fine *Cordylina indivisa*, and a healthy *Cycas revoluta*. Mr. J. Thompson was second with two *Crotons* and *Dieffenbachia gigantea*. Mr. Methven had the third prize. Ferns were not of remarkable excellence, although Mr. Tudgey exhibited creditable specimens, and won the first honours for six plants with *Gleichenias Mendeli* and *rupestris*, *Adiantum scutum* and *cuneatum*, *Gymnogramma Peruviana*, and *Pteris scaberula*. Messrs. Methven, Wilson, and Thompson also secured prizes. Some of the amateur exhibitors also staged fresh healthy medium-sized specimens, notably Mr. Henry Brooks, Shincliffe, and Mr. John Garrett, who were awarded the chief prizes in that section. In the classes for Heaths Mr. Moulton was unapproachable. His specimens of *E. tricolor* *Hoffordii*, *E. Austiniana*, and *E. Irbyana* were very fresh and well bloomed, and ensured him the principal prizes. In the amateurs' class Mr. Battensby exhibited a capital specimen of *Erica Marnockiana*; a plant so vigorous is not often seen of this variety. He also exhibited a very fine *Lapageria* and an excellent specimen of *Vallota purpurea* with thirty spikes—plants worthy of professionals, and which secured for the exhibitor the first prize for three specimens. Mr. W. J. Taylor's prize for three *Liliums* was won by Mr. Moulton with fairly good examples. Mr. Moulton had the first place also for *Coleuses* with compact and well-coloured plants. *Fuchsias* were not superior, and only one prize was awarded—namely, to Mr. E. Sandars. Table plants were not noteworthy, and *Cockscombs* were rather coarse.

CUT FLOWERS.—These were the great feature of the Show. The collections of Dahlias made a fine display, and almost astonished the Judge, Mr. C. Turner, by their numbers; several blooms were undoubtedly coarse, but the majority were of excellent quality.

Dahlias.—In the class for twenty-four blooms seventeen stands were exhibited. The county prize was won by Mr. W. Boston, Carthorpe, Bedale, with medium-sized, compact, well-finished examples of *Royalty*, Mr. Standish, *Royal Queen*, Mrs. Levington, Mr. Dix, *Julia Wyatt*, Mrs. Henshaw, Thomas Goodwin, Annie Neville, A. Crammond, Hebe, Lord Derby, Miss Turner, Ovid, *Yellow Boy*, James Cocker, *Criterion*, *Toison d'Or*, Dr. Moffatt, *Queen of Beauties*, *Flora Wyatt*, Mrs. Harris, *Cremorne*, and a white seedling of great merit. The second-prize collection of Mr. C. Ryland, Aughton, Holmskirk, consisted of larger blooms, some of which were of great excellence, while others were deficient in outline. Willie Eckford in this stand was exceedingly fine. The third prize stand of Mr. Henry Clark, Rodley, Leeds, also contained some very fine blooms, notably of Baron Taunton, Vice-President, and John Neville Keynes; and the extra third collection of Mr. Jackson, Kidderminster, well merited the approval of the Judge. Mr. Turner's fine new scarlet *Christopher Ridley* was well shown by Mr. Charles Ryland; and a grand bloom of the same variety, and bright and good examples of *Drake Lewis* and *Prince Arthur*, were staged by Mr. Charles Backhouse. Mr. Fletcher, nurseryman, Charlestown, Baildown, Leeds, won in the class for twelve blooms with John Bennett, Charles Leicester, Mrs. Harris, Vice-President, Lady Gladys Herbert, *Royal Queen*, John N. Keynes, James Cocker, Mr. Stanscomb, *Flora Wyatt*, Henry Walton, and Hon. Sydney Herbert. The second and third prizes went to Mr. G. H. Fewkes, Tyburn, Erdington, Birmingham. Mr. William Shaw, Blackbrook, Kidderminster, secured first honours in the class for twelve fancy Dahlias with *Prospero*, *Harlequin*, Miss Ann, *Flora Wyatt*, Rev. J. B. M. Camm, Annie, Miss Large, Fanny Start, Lord Hawke, *Octoroon*, Mrs. Saunders, and Mrs. Bennet—an excellent stand. Mr. Ryland had the second prize, and Messrs. Painter & Boston equal thirds—a capital class. In the amateurs' classes for six blooms Mr. Fewkes and Mr. Wardle staged creditable stands, and were awarded the prizes in the order named.

Hollyhocks.—In the class for twenty-four varieties five very good stands were exhibited, the first prize going to Mr. John Stairman, The Public Park, Darlington, with very compact fresh blooms of *Sanspareil*, Miss Chater, *Autumn Queen*, *Imperial Jewel*, *Queen of Yellows*, Mrs. Clarke, *Venus*, *Octoroon*, *Walden Queen*, *Pink Perfection*, *Edward Speed*, and *Adonis*. Mr. J. Thompson and Mr. Geo. Hankin had the remaining prizes.

Asters were tolerably numerous, and the winning stands of Messrs. Fenwick, Wardle, and Gardner excellent, and the same remark applies to French *Marigolds*. It was a treat also to see the twelve stands of *Pansies*, which were extremely fine for the period of the year, especially those of Messrs. Wardle and Oliphant. Seven stands of cut *Zonal Pelargoniums* were also very effective.

Capital Gladioluses were shown by Mr. Fenwick, Mr. Jackson, and Mr. Spoor, jun., who won the chief prizes in the classes for twelve and six spikes, but most of the varieties were unnamed.

The *Carnations* and *Picotees* were simply marvellous by their size and high quality, especially considering the lateness of the season. There were five stands of twelve *Carnations* and six of *Picotees*, and nine stands of six blooms were staged. The flowers were not named, but they reflected great credit on the exhibitors—Messrs. Flowdy, Scott, and Harland.

Roses were exhibited by the executors of the late Mr. John Harrison, Caterick Bridge, Yorkshire. The *Hybrid Perpetuals* were good, but the *Teas* were particularly fine, especially *Marie Van Houtte*, *Madame Bravy*, *Souvenir de Paul Neyron*, *Souvenir d'Elise*, *Catherine Mermet*, *Climbing Devonensis*, and *Perle de Lyon*. They had been grown in the open air.

The class for "eighteen groups of cut flowers on stands, tubes to be elevated 4 inches above the stands," was an unsatisfactory one. The bunches exhibited were in some measure imposing, but there was nothing meritorious about them. They were mere "handfuls of flowers," pretty enough but indistinct—were, indeed, bad bouquets. The only collection of real merit was a stand exhibited by Mr. Tudgey, but as it did not comply with the conditions it could only be recognised by the Judges as an "extra." They, however, very properly honoured it and themselves by awarding an extra first. The prizes in this class were offered by Mr. Bowman, horticultural builder.

TABLE DECORATIONS.—Liberal prizes were provided in this class by the President of the Society, Major Woods, Holey Hall. Mr. Moulton won the chief prize of £7 with a very tastefully arranged table. Besides the three principal glasses which were filled with flowers (*Pancratiums*, *Anthuriums*, *Miltonias*, *Dipladenias*, &c.), *Feather-grass* and *Ferns*, there were two small plants of *Pandanus Veitchii*; also good fruit—*Pines*, *Grapes*, *Melons*, *Plums*, and *Cherries*—a light and elegant table, which merited its position. The second-prize table of Messrs. Gellender & Sons, Newcastle, had a centrepiece of cut flowers (*Lapagerias*, *Stanhopeas*, *Liliums*, and *Allamandas*), two plants of *Reidia glaucescens*, semicircular troughs of flowers, and good

fruit. The third-prize table of Mr. Methven was also chastely arranged, and contained some excellent dishes of fruit.

Epergnes and bouquets were numerous, but several of them were too highly coloured. Those to which the prizes were awarded were, however, excellent. The first-prize bouquet of Mr. Poskett had a central flower of *Eucharis* surrounded with *Stephanotis*, *Ericas*, and light sprays of *Ixora*, also small *Oncidiums*, and a veil of gauze Fern. It was medium-sized and well executed. Mrs. Cramont's second-prize bouquet was composed of *Eucharis*, *Pancratiums*, and *Stephanotis*, relieved by small sprays of blue *Browallias* and Fern. Prizes were offered for baskets of cut flowers, and the several examples in competition produced rather an imposing effect; but on the whole the arrangements were too formal, and the flowers too much crowded.

FRUIT.—When the schedule was originally prepared fruit received but little consideration, and the prizes offered were quite inadequate to command good entries. An additional sum of upwards of £30 was subsequently added to the fruit classes, and a somewhat limited but very good display resulted. Mr. Westcott, Raby Castle, was awarded first honours in the class for eight dishes (*Pines* excluded) for an excellent collection containing remarkably good Black *Hamburg* Grapes and very good Golden *Champions*, also *Waltham Cross*; *Melons*, *Plums*, *Pitmaston Orange* *Nectarines*, *Barrington Peaches*, *Figs*, and *Apricots*. Mr. Jowsey, Sedbury Park, Richmond, secured the second prize, and Mr. Errington of Unsworth Hall the third for highly creditable collections. In the class for six dishes the prizewinners were Mr. Shaw, Blakebrook, Kidderminster, Mr. Westcott, and Mr. Wass in the order named, who all staged good collections. A few very good *Pine Apples* were exhibited, the prizes going to Mr. Brown and to Mr. Westcott. But a much better class was that for two bunches of black Grapes, the prizes being offered by Mr. Kinnear, Radcliffe House, which attracted thirteen competitors. The Judge (Mr. Rivers, Sawbridgworth) awarded the first prize to Mr. Witherspoon, Chester-le-Street, for medium-sized but handsome and well-coloured bunches of Black *Alicante*; the berries were very fine and regular, and the more creditable to the exhibitor (an amateur) as being the first Grapes he has grown. Mr. Westcott had the second prize with Black *Hamburgs* of great merit; if these had been placed equal first no injustice would have been done. Mr. Jowsey had the third prize. Mr. Westcott won the chief prize for white Grapes, followed by Mr. Bradley, gardener to T. S. Turnbull, Esq., High Barnes, Sunderland; and Mr. Stocksley, Elswick Park, for very good produce; and for the heaviest bunch Mr. Jowsey won with a well-shaped bunch of *Gros Guillaume*, weighing about 7 lbs. Fifteen *Melons* were staged, medium-sized good dessert fruit. Mr. Starrie, gardener to J. Noble, Esq., had the first prize. A few dishes of very good *Peaches* were exhibited, but owing to the dull weather some of the fruit was deficient in colour. Mr. Shields, gardener to Col. Reed, Newbiggen House, Kenton, had the first prize with a capital dish. *Nectarines* were small, as also were *Pears*. *Apples* were limited, but a few very fine dishes were staged by Messrs. Shaw, Brown, and Rylance. *Plums* were poor. *Cucumbers* large—too large, and unnamed. Mr. Rivers sent a collection of fruit in twelve varieties of *Pears*, *Apples*, *Peaches*, and *Nectarines*, many of them being new, and contributed much to the completeness and interest of this section of the Show. It is evident that good fruit is grown in the north, and liberal prizes only are necessary to ensure a fine show of it at Newcastle. Only a few vegetables were exhibited, but these were good; and Mr. Turner's Schoolmaster *Potato* was much admired. Many exhibits were not named, which always detracts from the interest and even from the usefulness of a Show.

The mode of affixing the prizes merits notice, as being the fairest, simplest, and best that has come under our notice. Every exhibit has a card attached containing the name and address of the exhibitor, together with the number of the class and description of the exhibit. This card is placed in an envelope and on which is the class number. After the awards are made, not before, the envelope is opened and the award of first, second, or third prize is pasted on—not anywhere, be it observed, covering important portions of the cards as at Carlisle, but in a space left blank for the purpose. Nothing can be neater, better, nor more expeditious.

The Show was a great success. Visitors crowded the Hall in such numbers and with such enthusiasm as are seldom seen. Newcastle is the centre of a population within a radius of ten miles of a million and a half. It has also excellent railway facilities. It contains men of horticultural skill and great administrative ability, and, moreover, whose nature to give a hearty, a courteous, a hospitable welcome to all comers aiding in the exhibitions which they have established so well. Newcastle can hardly fail to become an important horticultural centre, and great shows are certain to be provided so long as the same able and willing workers devote their energies to the work in which they are now engaged. We are glad to have visited this Show, and to have noted the extraordinary zeal of its chief officials,

and the none less useful if more obscure aid given by Mrs. W. J. Taylor.

SHANKING OF GRAPES.

"INQUIRER" raises a very important question when he asks "Why outdoor Grapes do not shank?" and as I think I can "read between the lines" that he wants to know why indoor Grapes do shank, I will put the two questions together and say, "What is the cause of shanking, and how can it be prevented or checked?"

First of all let us consider what is shanking. It is the small stalk which connects the berry with the bunch ceasing to convey nutriment to the berry, and consequently the berry comes to a standstill and the stalk withers. It generally takes place just when the fruit begins to colour, and the shanked berries remain red or green and sour. It will be found to occur most on Vines which have been grown in very rich borders with their roots unchecked during the first few years of their existence. The roots of Vines so grown do not ramify and make numerous feeders as those do which are grown in little else than loam. The less manure, so long as the soil is sufficiently fertile to promote good growth, the better will be the constitution of the Vine. It will have harder and more perfect wood, and also more numerous though not such gross feeders. The roots of Vines planted in richly prepared borders often dart straight through them without ramifying scarcely at all; not, perhaps, because there are not the necessary ingredients in the border for their sustenance, but because their wants are so easily supplied without, as it were, any effort on their part, and then, like people who are not early taught to cater for themselves, they do not find out the way till it is too late. As the roots, so the branches. If the former are gross the latter will correspond to them, and have a large amount of pith, long joints, and drawn-out cells. Very probably there are about the same number of cells whether the joints are near together or far apart, and a similar amount of solid material is built up in each case.

Shanking is very prevalent on Vines which are not allowed to carry sufficient foliage in comparison with the fruit they bear; in fact it can be produced on any Vine however healthy in two or three years if it is pinched-in too hard, or if a large portion of its leaves are removed just before the fruit ripens under the pretext of admitting light to the fruit, or because the leaves are required for garnishing. I guard very jealously all the Vine leaves on fruiting plants which can be exposed to the light till the fruit is perfectly matured. I would rather have the fruit taken than that the Vines should be partially denuded, and therefore leaves for garnishing are grown elsewhere.

Shanking is often caused, too, by an insufficiency of water. What I consider a sufficiency may be gleaned from the fact that four *Muscats* Vines, which now fill a compartment 80 feet by 30 feet of our large vinery, have been watered twelve times since the beginning of March, each Vine receiving about 300 gallons each time, although the area of the space containing their roots is only about 15 feet by 8 for each Vine.

Besides what I have pointed out there is no doubt that "INQUIRER" is right in thinking that high night temperatures have a good deal to do with shanking, and it may interest him, if he is not already acquainted with the fact, to know that I never aim at a higher night temperature than 55° for Vines, including *Muscats*, till the flowers are set, and further that *Muscats* always do set under such treatment as thickly as *Hamburgs*; they are, in fact, generally set and start swelling perceptibly before the cap falls off which covers the stamens.

There are several reasons for recommending a comparatively low temperature for the development of the flowers, but the principal are because the roots never start, and consequently cannot take up food, till some of the leaves are grown to their full size; therefore, if you force, all is coming out and nothing going in. Bottom heat makes no difference in this respect; you cannot start the root first if the Vine is healthy. And again, flower stalks if not grown sturdily at first will be very likely to break down when they become fruit stalks.

I had almost forgotten to note that outdoor Vines receive their greatest amount of water during winter, the soil in which they are growing never even approaching dryness at that time; neither does it in the houses of which I have charge. Watering Vine borders is a very frequent employment for wet weather during winter. The summer watering also does not stop when the fruit begins to ripen, as so many people recommend, but goes on rather increasingly towards the autumn

till the foliage falls, and then if the fruit is still hanging on the Vines it has to be done rather more carefully, choosing dry days for the operation, and afterwards sprinkling dry soil over the borders.

But "what about cracking?" Well, cracking is generally the result of insufficient watering at a certain stage; the berry gets hidebound, and then when water is applied the berry swells, while the skin having lost its elasticity cracks. Too much growth of foliage at the ripening stage will sometimes cause cracking; but, on the other hand, growth of foliage prevents shanking and helps colouring, therefore it must be dealt with very cautiously.

In conclusion, I have to say that shanking is not a disease; it can be produced at will by overcropping, defoliating, hard forcing in the first stages of growth, or semi-starvation; and that it is not incurable, although at times the remedy would be too costly, as it would take a considerable amount of time.—WILLIAM TAYLOR.

BRIGHTON AUTUMN SHOW.

SEPTEMBER 12TH AND 13TH.

WITH the exception of just one or two of the very great summer shows held in London, the Brighton Autumn Exhibition may be truly said to be equal in every respect to the rest of our London shows. It occupies a very high position as a provincial Show, and situated as it is in one of the most fashionable as well as one of the wealthiest of seaside towns, we were not surprised to see the numerous exhibits and the excellence of the productions exhibited. The schedule was both large and comprehensive, and both the inhabitants and county residents exhibit and respond with a spirit worthy of such a town. This Show was held in the Royal Pavilion, which is an admirable place for such a scene; and the brilliant company, the rank and fashion, shows that horticulture here must be advancing and going hand-in-hand with other sciences and institutions.

In the large tent were staged the specimen stove and greenhouse plants, Geraniums, Fuchsias, &c., and several of the spacious rooms of the Pavilion were filled with massive specimens of fine-foliage plants and Ferns, while other rooms were devoted to fruit and cut blooms of Roses. These two latter were represented most abundantly. The Committee and Managers of this most excellent Show will pardon us, we know, if we suggest that in future they should vary their productions and arrange them so that the fine-foliage and graceful Ferns should relieve and soften the glaring colours of the flowering plants, more especially the scarlet Geraniums, of which these occupied the whole length of one side of the centre stage without a break. Fancy a double row of Zonal Pelargoniums covering a space about 150 feet by 10 or 12 without an interruption of any kind, while in the dark rooms the fine-foliage and Ferns were placed alone.

Stove and greenhouse flowering plants were well shown considering the lateness of the season, and in the class for eight Messrs. Balchin & Nell, Western Road, Brighton, were a good first with *Allamandea paraxensis* and *Hendersonii*, *Ixora amblyonensis*, *Stephanotis floribunda*, *Ericas* retorta major and *Austiniana*, *Dipladenia Brearleyana*, and *Dracophyllum gracile*. All with the exception of the last named were exceedingly well bloomed. Mr. Meacham, gardener to C. Armstrong, Esq., Withdean, second; and in the corresponding class for four, Mr. Child, gardener to Mrs. Torr, Ewell, was first with splendid plants of *Bougainvillea glabra*, *Erica Austiniana*, *Allamanda Hendersonii*, and *Vinca oculata*; Messrs. Golding & Co. second; and Messrs. Miles and Verrall equal thirds. Other classes were set apart for stove and greenhouse plants open to the county only, in which several of the above obtained awards.

The principal prize of the day was one given by the Directors of the Brighton and South Coast Railway, a ten-guinea cup, for ten variegated or fine-foliaged plants, which brought together three collections. The first was gained by Messrs. Balchin and Nell for massive plants of *Croton angustifolium*, *pictum*, *variegatum*, and *Johannis*, *Phormium tenax variegatum*, *Cycas revoluta*, *Areca sapida*, *Encephalartos villosus*, *Pandanus Veitchii*, and *Phoenixophorium seychellarum*. Mr. Miles of the West Brighton Nurseries was placed second with plants somewhat smaller, but a very fresh and even collection, having grand examples of *Alocasia macrorrhiza variegata*, *Cycas revoluta*, *Euterpe edulis*, *Croton pictum*, *variegatum*, *interruptum*, and *angustifolium*, *Alocasia Lowii*, *Maranta zebrina*, and *Dracæna Shepherdii*. Mr. Meacham was placed third with much smaller plants, but they were good.

In the class for eight exotic Ferns Mr. Miles was awarded the first prize for grand examples of *Davallia Mooreana*, *Adiantum concinnum latum*, *farleyense*, and *trapeziforme*; *Cyathea arborea*, *medullaris*, and *dealbata*, the whole occupying a space of not less than 40 feet, completely covering one end of the spacious room. Mr. Child was placed second for good plants of *Todea superba*, *Gleichenias diacarpa* and *Mendeli*, *Adiantums*

tenerum and *farleyense*, *Davallia Mooreana*, *Dicksonia antarctica*, and *Cyathea dealbata*. Messrs. Balchin & Nell third with larger specimens still. The first prize single foliaged-plant was awarded to Mr. Miles for *Encephalartos villosus*; and for single flowering-plants Mr. Rutland, gardener to the Duke of Richmond, was placed first.

Zonal Geraniums, as we above intimated, were extensively shown, several classes being provided for them, and the distinction was zonal, not scarlet and zonal scarlet. Mr. Miles was here very successful, winning the two first prizes, while Messrs. Balchin & Nell were placed second in both cases. Other successful exhibitors in these and other zonal classes were Mr. Meacham, Mr. Howick, Mr. Townshend, and Mr. Wickham, the whole of them showing well grown examples of about 4 to 5 feet through, globular in shape, and free from any hard training. Perhaps the individual trusses were not so large as is to be met with about London, but they were in greater profusion. The best double Geraniums we have ever seen came from Balchin & Nell, who were the only exhibitors, but worthily deserved the first prize awarded to them. The varieties shown were *Jacoba*, *Sceptre Lorraine*, *Madame Lemoine*, and *Madame Schmidt*. Tricolors were on the whole small, and *Fuchsias* were very poorly represented both in quality and quantity—the worst we have seen for many a day. *Dahlias* were most numerous and exceedingly fine, Mr. W. Seale, nurseryman, Sevenoaks, being the principal prizetaker. *Asters*, *Gladioli*, and *Verbenas* were also very good, and the collection of twenty-four varieties of cut flowers set up by Messrs. Balchin & Nell was a masterpiece of arrangement; Mr. Morse, Epsom, was placed second with a very good collection.

Dinner-table decorations were also very good, and showed considerable taste in arrangement—the first-prize stands exceedingly light and graceful. Mr. Seale first; Mr. Downing, Crawley, second; and Mr. Miles third, all exhibiting well.

Thirty classes were set apart for fruit, which was both shown numerously and particularly good. Mr. Rutland was placed first for a collection of ten dishes, containing very large and well-formed bunches of Mrs. Pince's Muscat, but not quite ripe, very fine; Royal George Peaches, Morello Cherries, Golden Perfection Melon, Black Ischia Figs, Smooth Cayenne Pine, Pittamston Orange and Stanwick Nectarines, and Muscat of Alexandria Grapes. Our space will not allow us to particularise the many other exhibitors who deserved the prizes awarded to them, but mention should be made of a grand dish of Red Astrachan Apple shown by Mr. Worsfield, gardener to Lady Dickens, Horsham, and a very fine bank of decorative plants set up by Mr. Miles, occupying a space of not less than 80 feet by 20; this collection contained all that was new and useful in the way of Ferns, Crotons, Palms, and other plants used for decorative purposes.

ROSES.—We have left these for last, not that they were the least showy subjects in the Show, nor that they were not fairly represented, for they were shown most numerously, and from the numerous visitors that clung around them we had a difficulty in gaining the names of the principal prizewinners. Messrs. Mitchell & Sons, Piltown Nursery, Uckfield, took the first prize for forty-eight varieties in threes, Mr. W. Seale second, and Messrs. Virgo & Sons third. Mrs. Woolard, Mr. Piper, the Rev. C. Hales, Mr. Gravelly, Mr. Davis, and Mr. Marsh were all prizetakers. A box of twelve varieties of Tea or Noisette from Messrs. Mitchell & Sons were almost as good as those they took the first prize with at the Crystal Palace this season, and amongst them were Belle Lyonnaise, Devonienne, Perle de Lyon, Marie Van Houtte, Catherine Mermet, Adam, Madame Margottin, Souvenir d'un Ami, Elise Vardon, and Souvenir de Paul Neyron. All the Roses shown were very good for so late in the season, and from the extensive quantity exhibited it must be inferred that it has been a good season for autumnal Roses. We have other notes of Brighton horticultural doings which we must defer until our next.—J. W. MOORMAN.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

HARDY FRUIT GARDEN.

ALLUSION was made two weeks ago to the gathering of Apples and Pears. It will only be necessary to say now that the work must be proceeded with as fast as the fruit ripens, but it is not well to do this until it is quite ripe. Many persons have not patience to wait, especially when they see the fruit being daily shaken down by the wind; but if the fruit that falls is examined it will be seen that much of it has been attacked by the Apple maggot. Wall trees require to be looked over in order to secure the loose branches to the walls and also any young growths recently formed. Peaches and Nectarines ripening must be exposed to the sun. Many of the fruits are shaded by the leaves, and these must be removed either by picking them off or laying them aside. Vines on the walls will require similar attention to other trees; and, quite independently of the fruit that is pro-

duced, well-trained Vines look remarkably well on any wall, or trained to out-houses or the gable end of a dwelling-house. The bunches of the white varieties should be exposed to the sun when the berries become soft to the touch. In our neighbourhood they do not as yet show signs of being ripe early, but if the weather is fine for two or three weeks longer Royal Muscadine on a favourable position will ripen fairly. The small Black Cluster is also a useful Grape. These fruits are not much grown in aristocratic gardens where Black Hamburgh is grown under glass; but those who are not so fortunate as to own any glass structure can appreciate the Royal Muscadine from an open wall in favoured districts in the south of England. The lateral growths should be pinched off, and the young wood should be fully exposed to the sun. During mild dry weather about the end of September or in October red spider and other insect pests make much progress on the trees if they are not checked. As soon as the fruit is gathered from any of the trees the garden engine may be brought into requisition, and the trees be thoroughly syringed with clear water. If the trees are thoroughly cleansed from insect pests in the autumn they will not be likely to be attacked in the following spring or early summer.

There is usually a border in front of the walls, and this must be kept free from weeds and be raked occasionally. The crops that can be grown on such borders are Lettuce, Endive, and other small salads. If it is necessary to plant them with early Peas, Potatoes, or Beans, these crops ought not to be nearer the wall than 3 feet.

CUCUMBERS AND MELONS.

Preparation must now be made to plant out the Cucumbers for winter bearing. It is not well to delay this too long, else the plants do not become well established before the dull dark days of November. The trellis ought to be well covered before the first week in November, and the plants must not be allowed to bear too much after that date, else speedy exhaustion will follow. Before planting-out see that the house is thoroughly cleansed by washing the glass and woodwork; the hot-water pipes should be painted, and the walls washed and be afterwards painted over with lime water. If there are any plants in the house infested with insect pests, such as red spider, thrips, or mealy bug, they must either be cleaned or removed. If the Cucumber plants are quite free from any of them when they are put out probably they will not be attacked in the winter if proper precautions are used. It is not desirable to make a large border for the roots, a space for the soil about 2 feet wide and from 9 inches to a foot deep is amply sufficient; the roots work near the surface more in a shallow border, and they can be encouraged by frequent dressings with rich soil. In the Cucumber house at Loxford the beds are much wider than is necessary, and our plan is to build a wall down the centre of the bed with bricks, not using any mortar. On one side of this wall is the compost for the plants, on the other some fermenting manure. This bed of manure answers two purposes—it excites by its warmth to immediate root-action the newly-planted Cucumber plants, and the bottom heat is very useful for propagating purposes; moreover, insects do not like the moisture from stable manure in a fresh state.

Melons on which the fruit is ripening should have a rather dry atmosphere, the house should be freely aired, and the temperature at night to range between 60° and 65°. When the fruit is not in such an advanced stage as this the usual precautions must be taken to keep the leaves free from the attacks of red spider. Too much syringing is apt to injure the plants by causing them to rot off at the neck. It is best to syringe thoroughly during the mornings of fine days; 65° at night with a rise of about 10° by day is a very suitable temperature.

GREENHOUSE AND CONSERVATORY.

Where there are large houses and pits devoted to the culture of greenhouse plants there is plenty to do all through the season. At present the winter-flowering plants demand attention. Before this appears in print a batch of Hyacinth and Tulip roots will probably be potted for early flowering. We pot one root in the centre of a 5-inch pot, or three small roots in a 6-inch. When potted the pots are placed on a hard bottom of ashes, and are then covered over with cocoa-nut fibre refuse. Cyclamens have also just been potted. Those in 7 and 8-inch pots were turned-out of the pots, the balls of earth considerably reduced, and the plants were again potted into similar pots from which they had been turned out. *Primula cortusoides amœna*, and varieties white and lilac, have also been repotted. Before doing so the plants were separated, each clump being broken into four or five pieces, and when potted in fresh pots fresh compost was worked-in between them. The Cape and New Holland plants potted a few weeks ago have taken kindly to the fresh compost and are making fresh roots abundantly. The house was kept rather close for a few days, but we now ventilate freely, leaving the ventilators open at night as well as in the day. Some of the plants require to be staked-out, but this is work that can stand over for a time, and it is just as well to leave such work if possible for rough weather later in the

year. It is best to use sticks made of good deal for hardwooded plants, and strong black linen thread to tie with. The sticks should be painted of a green colour. Most of the buds on Chrysanthemums are now set and swelling freely. The late-flowering sorts, such as Princess of Wales, Princess Teck, Her Majesty, Lady Slade, Venus, &c., should be set the last week in August, or at least in the very earliest days of September, the early-flowering sorts a week or ten days later. Now is the time to look out for mildew, not only on Chrysanthemums but many other greenhouse plants, including Cinerarias, also Heaths and many other similar plants. Sulphur thrown as a cloud of dust on the leaves will soon destroy it in its earliest stages.

FLORIST FLOWERS.

In writing two or three weeks ago on Auriculas it was stated that a certain variety was "dorty," a phrase much used in Scotland, but the printer made it out "dirty," which is a blunder. Auriculas are now making their autumn growth, but many of the plants are also showing trusses of bloom. We do not find that these interfere much with the spring bloom, if they are picked off as soon as possible a new heart is formed in the course of a few weeks; the plants require picking over again to remove the decaying leaves and weeds. The plants are still under the shelter of a north wall in frames, and the lights are removed as often as weather permits. We never allow the leaves to be exposed to rain; as they are sheltered by the wall high winds do not injure them.

Pinks.—The earliest-struck pipings of these have been planted out in the beds where they are intended to bloom. It is usual to plant them in October, but we would rather plant about the middle of September, when the plants have been duly hardened off. The treatment so far is this—about the end of June or early in July the pipings are put into boxes, and they strike out roots in about two weeks, aided by a little bottom heat. When it is seen that the plants are rooted air freely, removing the lights altogether in calm weather. After a while, say from the beginning to the middle of August, remove the boxes to an exposed position out of doors, and then plant out the young plants 3 inches apart in a bed of light soil. In a month after being planted out they are ready for removing to the beds where they will flower. Plant in light rich soil 9 inches apart, or less if space is limited. We have just finished potting-off the Carnations and Picotees. We pot a pair in a small pot except scarce and choice varieties, these are placed one in a pot. It would be as well to pot the plants singly, but then it requires a double quantity of pots, and we cannot spare frames for so many. The only pest to us is the wireworm, and as it works like the mole under ground it is very difficult to catch it until the plant is destroyed. We pick the soil over carefully two or three times before potting, as a wireworm in a pot is sure to destroy at least one of the plants, probably both. The potting material is of the simplest description—loam four parts, leaf mould one part, rotted manure one part, and some sand to keep the compost open.

Pansies.—Cuttings of these were put in a few days ago and they have struck roots freely. The young plants are speedily attacked by green fly and mildew under glass. It is best to turn them out of doors as soon as they are rooted. We have also pricked-out a number of seedling Pansies, intending to plant a bed of them about the end of October.

Dahlias and *Hollyhocks* require attention. All flowers that have begun to decay should be at once removed. The shoots should be tied to the sticks to prevent their being broken by the high winds prevalent at this season. See that the ground is kept free from weeds and the plants from decaying leaves.—J. DOUGLAS.

DEATH OF PROFESSOR PARLATORE.—It is with much regret that we have to announce the death of Filippo Parlatore, Professor of Botany at Florence, of which we received an intimation as we were going to press. Professor Parlatore died full of honours on the 9th of this month at the age of sixty-one. The list of honorary distinctions which accompany the announcement of his death occupy nearly a whole page of a quarto sheet.

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

FUCHSIAS (*Mr. Boyle*).—*Fuchsias virgata* and *gracilis* are not identical. The window plant you describe is probably *Richardia* *æthiopica*.

VINES IN POTS (*S. N.*).—You may grow them for one year, and then turn them out into the border. The spray you enclosed is *Pyrus Aria*, the White Beam Tree.

TREES FOR SEASHORE (H. Horton).—Evergreen Oak, *Pinus insignis*, P. Lario, with Sycamore and Turkey Oak, are what we advise of trees; and of shrubs Tamarisk, Alaternus, Brooms, double Gorse, Eucalyptus, Escallonia macrantha, Hollies, Elders, Sea Buckthorn, and Gaudier Rose.

ROSE (H. E. Holdaway).—The specimen was a mass of dead leaves attached to a dried and withered stalk. It ought to have been sent in a box wrapped in damp moss. The naming must be a matter of conjecture. It may be Jean Cherpin, and we think it is.

BEECH NUTS AND ACORNS.—“W. L.” writes that the Beech nuts are very abundant near Bromsgrove, but that acorns are very scarce. He asks if Beech nuts are plentiful in other parts of England.

CINERARIA LEAF DISEASED (R. K. Penson).—It is mildewed, and the cause is too much moisture and too little ventilation.

WATSON'S LAWN SAND (C. M.).—Not having tried it we cannot give an opinion.

TURF FOR VINE BORDERS (Nemo).—The best material for Vine borders when turf cannot be obtained, is to take as good soil as you can get, to eight barrowloads of it add one of lime rubbish, one of rotted manure, a peck of charcoal, and the same quantity of inch bones, turn it over twice, and use it at once.

NEW ZEALAND FLAX FROM SEED (J. S. W.).—You may sow the seeds now in light soil, place the pots in heat, and do not give much water—just sufficient to keep the soil moist. The seeds take a good while to germinate, but those sent are good. When the young plants have grown a little prick them off, about nine in a 6-inch pot.

ARAUCARIA SEEDLESS (J. R. W.).—You are correctly informed. This tree is dioecious.

GLASS-COVERED WALL FOR PEACH TREE (R. R.).—As you have provided a coping would it not be as well to wait until your trees are old enough to bear, and see whether you cannot obtain a crop without any glass protection? Should you determine to have glass, we advise a simple lean-to, with ventilation provided at the top by moveable lights to lift up by an iron rod. The front ventilation should be provided by shutters to open outwards under a plate on which the base of the rafters should rest. The shutters may be about 12 inches wide. You say the trees are against the north wall; we presume, of course, that the wall faces south.

HYDRANGEAS IMPERFECTLY DEVELOPED (H. C. P.).—We cannot account for this in any way, if the plants are healthy and growing strongly, except that it may be owing to the unfavourable weather we have experienced. The plants like generous treatment, and when the flower-trusses are forming to be exposed to light and air.

VINES NOT STARTING INTO GROWTH (J. A.).—We do not quite understand what you mean by saying “the Vines made several attempts to break but failed.” How were the attempts made? If they have not made any growth during the season they must be pronounced to be dead, and others should be planted in their place.

POT CULTURE OF LILIUM AURATUM (Ightham).—We agree with Mr. Wood in thinking the present time of year the best for repotting, but we do not attribute his success solely to doing so, and have no doubt that you may obtain equally satisfactory results if your bulbs are as large as his; size of bulb has much influence in the matter. Shake out the three bulbs which you have in a 10-inch pot and repot them singly in 8-inch pots, placing the tops of the bulbs quite 2 inches below the surface. Plunge the pots in coal ashes in the open air, and when the leaves of the next season's growth appear give plenty of sewage or other liquid manure.

STEPHANOTIS FLORIBUNDA FRUITING (A Constant Reader).—Old plants of Stephanotis occasionally bear fruit, but it is unusual for fruit to be borne annually, or with any periodical regularity, upon the same plant.

LEAKY GREENHOUSE ROOF (Ten-years Subscriber).—Scrape away the old putty from the faulty places, cleanse well with a dusting brush, give one coat of paint, then stop thoroughly with putty and follow with three more coats of paint. A leaky roof is a sure indication of neglect. Why does your putty perish so soon? Simply because you have not applied the annual coat of paint which the woodwork and putty of every glazed structure should have.

FIGS (E. F.).—You may plant against your west wall the Brown Turkey and the Brunswick.

WITLOOF (R. G.).—The leaves are eaten as Seekale and uncooked as a salad. There are full particulars and a drawing of the plant in the number of this Journal published January 27th of last year.

ANALYSES OF FLOWERS (G. N. T.).—There are many published in Dr. Thomson's “Organic Chemistry—Vegetables.”

NAMES OF FRUITS (Elm).—1, Magnum Bonum; 2, Victoria; 3, Fotheringham; 4, Lucombe's Nonsuch; 5, Winesour; 6, Orleans.

NAMES OF PLANTS (C. T.).—2, Eucalyptus europæus; 3, Cornus sanguinea; 4, Acer campestre; 5, Polemonium caruleum variegatum. (W. W.).—Inula helenium. The root is tonic. There is no mode of destroying it but by spudding it out, or paring and burning the top spit of the field. (J. C. O.).—It is the Grass of Parnassus, Parnassia palustris. (A. H. S.).—1, Cattleya, probably C. Loddigesii; 2, Lycaste macrophylla. (Mrs. St. John).—Eupatorium Wendlandianum. (Mac.).—Potentilla fruticosa. (H. Dunning).—Specimens unsatisfactory. 1, Onoclea sensibilis; 2, Pteris (?) cretica; 3 and 4, Adiantum sp. (G. Chisholm).—Probably a Cistus, but specimen insufficient. (M. P. Horsham).—1, Solidago lanceolata; 2, Hibiscus syriacus; 3, Clethra arborea. (W. D. H.).—Euphrasia (Bartsia) odontites.

POULTRY, BEE, AND PIGEON CHRONICLE.

THE ISLINGTON AND ALEXANDRA PALACE SCHEDULES.

BOTH these schedules are to hand, and on both we have some few remarks to make. We extremely regret that the three A's—Aquarium, Alexandra, Agricultural Hall—have not in their own interests arranged their dates better. With the Sydenham meeting in prospect the London shows will surely suffer; and we verily believe, had any one of them lowered their entry fee

to 6s. instead of 7s. 6d., that the one so doing would have been the successful meeting. In bygone days when the great metropolis only had the Crystal Palace Show it was all very well to charge so high a rate of entry fees; but now that four of them have come into existence, and when there is even a prospect of a fifth, “Ichabod” may be cried over the prestige of winning in London, and the fees should surely be lessened in consequence if a number of entries is desired. In the face of these thickly coming shows we think Mr. Nicholls has been wise as well as the Islington Committee to have their classes for pairs of birds in most of the breeds. We know fully well that for chickens it is disadvantageous to show them in pairs, but we believe the outlay of money to form a double set of prizes for cockerels and pullets would not be recouped in a sufficiently satisfactory way to justify the expenditure in this time of glut of metropolitan shows.

We will speak of the Dairy Show first, as that is the first to come off. The prizes are liberal, £6 being divided in most classes in four prizes. In Dorkings, Silvers, Whites, and Cuckoos all have to compete together. Minorcas and Andalusians have a class together. Brahmas and Game have separate classes for the sexes, of which Brahmas have four and Game six. Poland has two classes, in one of which Whites, Chamois, &c., may appear. Hamburgs and Cochins have a good provision made for them. For the Variety class are left La Fliche, Sultans, Silkies, Cuckoo Cochins, Frizzles, &c. The Waterfowl are well cared for; besides the ordinary classes Cayugas, Pekins, East Indians, Mandarins, and Carolinas are all provided for. There are no Pigeon classes. The Selling divisions, however, will contain, we suppose, some good birds, for the entry fee is only 5s., and in each class £8 is given in prizes. The Bantam classification is odd; for as the classes read we should conclude Class 47 was for Black Game Bantams, whereas Black Rose-combs we suppose are intended to be entered here. All the other variety Bantams are jumbled up in Class 50. There are optional champion sweepstake prizes; medals are to be awarded for incubators, appliances, and poultry foods. There are also special prizes offered by the manufacturers of various foods for the best birds fed upon their compounds, which prizes will probably give the Judges much trouble and be of no real benefit to the poultry cause. Mr. F. Wilson, late of the Crystal Palace, is the Secretary, and Mr. R. R. Fowler is not this year to be the Steward we learn. We have only three more things to mention in connection with this schedule—the one that the cups and special prizes are to be given in addition to the money prizes, and that the birds exhibited will have to be away from home at least eight days, and in some cases probably more where the distance is great, which fact in the case of chickens of the year must surely lessen considerably the number of entries; and that the Judges are Messrs. Hewitt, Leno, Martin, Nicholls, Smith, and Teebay; but as the classes in which each gentleman will award the prizes are not named this piece of information could as well have been omitted for all the good it can do.

Among the rules and regulations of the Alexandra Palace we find one which tells us that only appeals from the Judges' decisions will be entertained when fraudulent practices have subsequently been discovered, in which case the prizes will be withheld. We read, too, that the prices of birds may be reduced on the second and third days of the Show; but a wise addition has been made to the ordinary words—viz., “Upon the production of the receipt for entry fees.” We are sorry, however, to see, that though the Judges' names are announced, their individual classes are not named. We see Mr. Mathews is down in conjunction with Messrs. Hewitt and Teebay for poultry; while Messrs. Esquilant, Heaton, and Tegetmeier take the Pigeons. The poultry have twenty cups and Pigeons twenty-one, varying in value from £10 10s. to £3 8s., some of which are presented and some subscribed for. Langshans have a cup and a class, the former given by the Club. Black Cuckoo and White Cochins have to compete together. We should have felt inclined to have made the classification larger and left out the £5 5s. sale classes, as there are now so many other opportunities of buying birds at a moderate price. Brahmas have classes for cockerels and pullets, two £5 5s. classes, twenty-four prizes and four cups, one of the value of £10 10s.; but we are certain the display of Darks has not of late been sufficiently good in quality or quantity to necessitate such a bountiful prize list. There are classes for Pile Game, Malays, three sorts of Polish, Silkies and Andalusians. There are nine £2 sale classes and four prizes in each class, and this department will probably be remunerative, though we doubt if the French require two of the divisions to themselves when Dorkings, Cochins, and Brahmas have only three between them. The Bantam classification is excellent, and the display should be good.

The Pigeons follow. Pouters, Carriers, Dragoons and Tumblers should come in swarms; all colours, varieties, and ages have rare chances of showing the quality of the fancy, while Jacobins, Owls and Turbits are handsomely seen to. We are glad to see separate classes for Fantail cocks and hens, and that Blacks and Blues have a class to themselves. Nuns, Trum-

peters, Magpies and Runts will all find a warm welcome in their own divisions. Two flying classes finish a capital schedule, one which is not as elaborate as some we have seen, but sufficiently well drawn up. We hope to enlist the hearty co-operation of all fanciers, and we have Mr. Nicholls's promise that every attention shall be paid to the speedy putting-up of the prize cards, so as to set an example to his somewhat tardy friends of other metropolitan shows. We earnestly hope the entries will be large, and that birds will be reserved to make a *début* at this and the Oxford Shows, whose dates most certainly are the most compatible with the welfare of young and growing stock. The entries close on new Michaelmas day, before which time we hope Mr. Nicholls will publish the separate work of each adjudicator among the various classes.—W.

GRANVILLE POULTRY SHOW.

THE first Ramsgate Show was held at the Granville Marina on Tuesday last and the following days. The entries were tolerably good, the names of a number of exhibitors from France and Belgium appearing in the prize list for the first time in England. The management, we regret to say, was not all that could be desired. Some of the pens were not up and a large number of the birds were in their baskets at the time the judging should have been almost completed. Many of the prize cards were not on the pens when we visited the Show at twelve o'clock on the second day.

Dorking cocks, coloured, only eight entries, and the pens not all full. Peel first, a fine old bird well on the feet and in fine condition. Second a little out of feather: this should, we think, have given way to Mr. Burnell's cockerel. Third a nice bird in good condition. Coloured hen, Burnell first and second with good birds. Silver-Gray.—The cocks with the exception of Mr. Burnell's were a poor lot. The second was fair in colour but small. Nearly all the rest had spurs growing in all directions. The hens were much better, and the competition rather close. *Cochins*.—Buff cocks moderate. First (Mrs. Tindall) a nice coloured chicken, but do not think he will ever make a great bird. Hens, first (Mrs. Tindall) a large hen, but not in condition for an exhibition pen. Second (Christy) a fine hen in lovely condition. Third large, but deficient in leg-feather. Any other colour cocks, first a White in beautiful condition and well shown, but for points we liked Mr. Darby's unnoticed pen better. Mrs. Tindall showed some very fine well-marked Partridge hens; had a cup been given for the best in the Show it must have fallen to the first-prize hen in this class. *Brahmas*.—Dark: First a good-coloured bird, well grown but vulturized. Second a good old bird, but will show to better advantage after his moult. Third and fourth good chickens; the former should perhaps have had a better position. The fifth award we did not like. Hens: The majority of the birds in this class were pullets, and with the exception of the second-prize, a grand hen well marked which we thought should have been first, we consider them a very even lot, and we doubt if any two judges would have made the same selections. Light: The winner a good bird, but so yellow that we think he should be out of the prize list. The second was a beautiful young chicken, and we should have liked to have seen him first. Hens: Nearly all young in this class and very equal in merits, and we think the Judge's selection correct. Cocks: Black Reds, a small class but good. Hens more numerous and equally good; the winner, a beautiful pullet, also obtained the cup. In the other *Game* classes the most noticeable was a fine Brown Red cock of wonderful style shown by Mr. Matthews. *Hamburghs*.—Many of the best birds were out of condition. *Spanish*.—Cocks: Some forward young birds were shown in this class, but they had no other merit. Hens: Mr. Jones's unnoticed pen 280 we thought far the best bird in the class. The three first-prize birds were exceedingly coarse. The fourth had a very small face and no lob. *Houdans*.—Both classes were large. In the cocks the first and fifth prizes went to France, and of the hens the fourth. *Crêpes*.—Capital classes, in quality better than the Houdans, our continental friends again coming in for a good share of the honours. *Polands*.—With one or two exceptions poor. *Leghorns*.—A nice class. *Game Bantams*.—Mr. Entwistle here exhibited a few good pens of *Game*. Mr. Morgan's cockerel in the second-prize pen we also liked.

The *Pigeons* were a very good collection, numbering nearly four hundred entries. The cup went to a Black cock, very long in neck and standing well on the legs, but hardly so heavy in eye and beak-wattle as others in the class, still he is a grand bird and well deserved his position. Of late there has been a tendency amongst some judges to look at nothing but "stuff," but we are glad to find that Mr. Tegetmeier has also an eye for grace and beauty, two most important properties in a Carrier. The first-prize hen was a beauty in all points. The winning Blue cock was a nice bird but cloudy in colour. Pouters were fair, the cup Black cock a capital bird. Barbs were a strong class of nineteen, the cup going to a Red with a good head. Jacobins were another strong class, but with the exception of

the prizewinners they were poor. Fantails good. The cup for Turbits went to a Red in beautiful condition, and exceedingly good in beak and colour. In English Owls first was a well-known winner, and now he will have to take his place amongst the champions at the Aquarium Show. Foreign were good, also the Tumblers. Dragons were a nice lot, but hardly so numerous or the quality so even as we have seen. The first-prize Blue Chequer cock was very good in colour and style. Both the show and homing Antwerps were well represented. Runts were capital. The Variety was a strong class; many other birds in addition to the prizewinners were well deserving of prizes.

The Judges were for *Poultry*, Messrs. Hewitt and Teebay; and for *Pigeons*, Mr. Tegetmeier. Mr. Esquilant was also announced as one of the Pigeon Judges, but he did not officiate.

FARNWORTH POULTRY SHOW.

THIS Show took place on Thursday last in the usual field, but unfortunately the weather was very unfavourable, as the rain commenced early in the morning and continued the whole of the day. The entries were but 195 in all, though the list is a very good one, the prizes being in most classes £2, £1, and 10s. with the addition of eight silver cups of the value of £35.

Dorkings headed the list with six entries, and the birds of fair quality. *Brahma* chickens were a good lot, the cup going to a pair of Dark chickens, the best that exhibitor has had out this season, except that the pullet carried her tail on one side. We considered pen 281 (Lingwood) should have had a place. In old birds Light were placed first, but we preferred Messrs. Duckworth's pen of Dark ones. *Cochins* (young).—First a grand-shaped pullet, pale in colour and far too much hock, with a leggy thin cockerel very mealy on the wing; second by far the best as a pair, very high in colour and better in Cochins shape; the third losing by very little. Partridge chickens very good. Cinnamon or Buff (old birds).—First a pen that have been good, but altogether out of it here. Although the cup was awarded to them they were in the most ragged plight and out of shape, Mr. Tomlinson's birds being much more to our taste, being higher in colour and in good order. Any other old birds.—First Partridge, the hen good and well marked but out of order; the cock altogether devoid of fluff and leg and foot feather. The best were Pen 303 (Perceval), in grand order, and the cock an enormous capital-shaped bird. *Game* (Black Reds).—First a good pen, the pullet very good in all points, the best cockerel in the class being the third (Pratt), but the pullet had a dark eye. Brown Reds were a raw young lot, but the first very good. In the Variety class Piles won, as also the cup, but the cockerel was very bad in colour on the tail hackle. *Spanish* were very good in all respects. *Hamburghs* had four classes, and the cup awarded to a grand pen of Gold-spangles. *Polish*.—First and second Black; the second, by far the best, were perfectly dry when judged, but the first were as wet as could be, and it puzzled us how the awards were so made. In the Variety class first were Black Hamburghs, second Crève-Cœur, and third Leghorns; all good pens. In *Bantams* the cup was won by a single Pile cockerel, a capital coloured bird; the classes generally good. In the Variety class Black Rose-combed were first, Silver Sebrights second, and Pekins third. *Ducks* were an excellent section, the cup going to a fine pen of Aylesburys.

JUDGES.—Mr. R. Teebay, Fulwood, Preston; Mr. G. Fell, Springfield, Warrington.

GOSSIP ABOUT BEES.

Two or three months ago while on a visit to England a Swedish gentleman came to Sale to see me and learn all he could about our hives and system of management. He is an extensive and intelligent apiarian in his own country, but had been rather unsuccessful with a kind of hive which is some-

what popular in this country. Questions by the score were put and answered; first and second swarms were taken from their hives, and queens transferred from one hive to another in his presence. Then he entered our dwelling house to get a cup of tea with my queen bee. The bread and butter was welcome enough, but he was more hungry for every scrap of bee knowledge that he could pick up and carry home to Sweden. He and his family possessed thousands of acres of land covered with good pasture for bees, and he said he would establish an apiary of hundreds of hives made after the fashion of those he saw here. "Why don't you yourself keep hives by the hundred instead of the dozen?" is one of the last questions he put to me.

Some of our customers for honey on finding that it is all sold ask, "Why not keep more bees?" This question has often risen up in our minds, and been answered by the fact that our occupation of gardening is quite enough for our declining strength and energies. Bee-keeping is but an adjunct of secondary importance here, but it is an adjunct that yields a great fund of enjoyment and a large margin of profit.

Between thirty and forty years ago we were sent by the late Dr. Lindley to a situation as head gardener. In this situation we found some things of a disquieting character. The servants of the house had access to the fruit (there being no walled garden), and the housekeeper and her friends were allowed to take what they liked best, and sometimes the under gardeners were blamed for what was missed. Then I was strongly tempted to entertain the thought of abandoning the occupation of gardening and betake myself wholly to bee-keeping. But we bore the disquietudes of the place as well as we could for two or three years. Our next situation was an exceedingly comfortable one, and so we have continued at gardening up to the present time. Our confidence in bee-keeping rather increases than abates. Any active man with a knowledge of bees may earn a substantial and good living from them. We were born and brought up in the midst of successful bee-keeping, and the impressions we received in early life have been deepened by a life-long experience. In making these remarks our object is not to tempt anybody to leave his calling or occupation and betake himself wholly to bee-keeping: it would be risky in our opinion to do so, and it might be ruinous. All beginners in every trade and line of business have difficulties to overcome. To all who contemplate bee-keeping on a large scale we would suggest caution, and that a commencement be made with bees as a remunerating adjunct for two or three years, so that the right way be felt, an experience gained, and a market for the produce found. Bee-keeping to us and many others is a source of profitable enjoyment, and to many more moving in the higher walks of life it is a source of pleasant recreation. To the sons of toil we have commended bee-keeping. To well-behaved and well-intentioned and industrious working people we more strongly than ever commend bee-keeping. To those who are partially disabled for hard work, to widows and others in straitened circumstances, bee-keeping in its simplest form would be a great helper. I have only one aunt surviving, about ninety years of age; after an experience of seventy years amongst bees she holds to their worth with a certitude of grasp, and no wonder, for she has found them to be a source of support to her during her widowhood. Last time I was in Scotland, about six years ago, her first swarm that year had gained 60 lbs. weight on the heather, and she had realised 200 lbs. (£10 worth) of honey from four stocks of bees. But few £10 will be realised this year from bees, I fancy, for I do not remember a worse season; at any rate, I never had bees to manage in a worse season. For a series of years we have had cold late springs, but this year we have had a cold, late, rainy summer, which has been most disappointing and discouraging to apiarians generally, especially to beginners who have never yet had a remunerating return from their bees. With strong hives in our possession we know how difficult it is to subdue the felt impatience for sunshine. We are in no mood to stint our sympathy for beginners who have had their hopes blighted this year. It is not a pleasing thing for bee-keepers to balance their gains and losses at the end of such a season as the present one. We have taken but one hive of honey (15 lbs. only), sold some stocks, and placed about forty stocks in our garden for another year. Our expenses so far are greater than our income. If we part with a few more hives the balance will be placed on the right side, and our stocks then will be as numerous as they were at the commencement of the season. Let us all look forward hopefully, and believe what Mr. Gladstone told some excursionists lately amid a downpour of rain—viz., "when things are at their worst they grow better."—A. PETTIGREW.

OUR LETTER BOX.

SILVER-GREY DORKINGS AT THE CRYSTAL PALACE.—"May I, as in former years, appeal once more through your columns for aid towards a five-guinea cup for the best adult Silver-Grey Dorking cock or hen at the next Crystal Palace Show? My apology for so often begging for this class must be that I have never myself won the cup for which I collect. If subscribers are kind enough to send me their subscriptions without my writing to them personally they will confer an additional favour.—O. E. CRESSWELL, *Early Wood, Bagshot, Surrey.*"

POULTRY HOUSE (*An Irish Subscriber*). You will find plans in our "Poultry Book for the Many."

BRABRA VULTURE-HOOKED (*C. S.*).—Vulture hooks are a great disadvantage to Brahmas, and should never be seen on a prize bird. It is only of late they have been shown, and the sooner they become extinct the better. They are a deformity, and cannot be credited with the least usefulness. A Brahma hen should have no black in the wing.

DUCK MANAGEMENT (*Constant Subscriber*).—The drake, having been the stock bird for three years, should now be set aside for a younger one. Ducks lay the greatest number of eggs the first year. Their eggs are more to be depended upon as fertile the second year, and after the third they should be put in a pie and their places filled by younger birds.

AYLESBURY DUCKS (*W. H.*).—Yellow bills demonstrate that the birds are not purely bred. The following are the requisite characteristics—plumage spotless white, bill pale flesh colour, legs orange.

GREY LINNET (*A Constant Reader*).—The bird pecking at his feathers so much is undoubtedly caused through the vermin or bird lice infesting its habitation. You have a remedy by changing the bird's quarters, and that must be effected speedily, especially as the system is in a poor state now the bird is moulting. Remove the bird into another cage whilst you destroy with turpentine or naphtha the vermin secreted in the infested cage. After well scalding and cleaning the cage will be again fit to use. Linnets in their wild state eat many kinds of seeds, especially rape seed, cabbage seed (not winter cabbage seed), poppy, dodder-grass seed, berries, and buds of trees. In confinement they will live best on summer cabbage seed, which does not require to be soaked as for Chaffinches, as Linnets have a powerful crop and stomach, and can therefore better digest the seed. To our Linnets, which we let fly about with some Canaries, we give Canary, summer rape, linseed, and only very sparingly indeed of hempseed. Linnets require exercise, more so than Canaries, and if they be too well fed in cages they often quickly die from over-feeding and want of exercise. They like to peck at salt, and it is necessary to occasionally supply them with a little. It is an excellent preventive against disease. Train your Linnet to use the bath. Some birds will very quickly take to it, and even over the moult it will do more good than otherwise. Birds should be freely supplied with sand and water.

BEES UNDER A FLOOR (*W. Hurst*).—If you can remove the boards above the bees, and cover them all round with a handkerchief or thin rag wet with chloroform, they will rapidly drop from the combs in a helpless state and remain motionless. As soon as this shall take place cut all the combs out and place them in an empty box or milk-pail for removal. If you have not courage to do this, you, perhaps, could fill the cavity which the bees inhabit with the fumes of sulphur or powder, and thus destroy the whole swarm. Seek the assistance of any old bee-keeper in your neighbourhood.

FERMENTING HONEY (*Dorset*).—Warning your honey before the fire will not prevent fermentation, but rather increase it. Some American bee-keepers boil their honey when fermentation begins. Boiling may act for a time, and is probably the best thing that can be done to hinder the fermenting process. As soon as any of our honey begins to ferment we boil it, and then give it either to poor people or weak hives.

METEOROLOGICAL OBSERVATIONS.

CAMDEN SQUARE, LONDON.

Lat. 51° 32' 40" N.; Long. 0° 8' 0" W.; Altitude, 111 feet.

DATE.	9 A.M.				IN THE DAY.						Rain.
1877	Baromet- er at 32° and Sea Level.	Hygrome- ter.		Direction of Wind.	Temp. of Soil at 1 foot.	Shade Tem- perature.		Radiation Temperature.		In. — 	

REMARKS.

- 12th.—Fine bright morning, pleasant day, though there were two or three slight showers; rain at 9 P.M., but starlight at midnight.
 13th.—Rather a grey day, with a little rain.
 14th.—Dull, damp, and showery all day; high wind all night and till 9 A.M. on the 15th.
 15th.—Wind and rain in early morning, rather dull forenoon; fine afterwards.
 16th.—Fair but dull early, getting gradually finer; very bright in the afternoon and evening.
 17th.—A very fine and pleasant day, though not very sunny.
 18th.—Bright and fine all day; much more sun than there was yesterday.
 A dry fine week; very cold in early mornings of the 16th and 17th.
 ERRATUM.—Barometer at 9 A.M. on 11th should have been 29.816, mean for last week 30.000 ins.—G. J. SIMONS.

COVENT GARDEN MARKET.—SEPTEMBER 19.

A VERY steady trade has been done during the past week with scarcely any alteration in prices. Kent Cobs have met with a ready sale at slight advances but show signs of a reaction, the supplies being very heavy the last two days. Pines in demand.

From observations taken near London during forty-three years, the average day temperature of the week is 65.6°; and its night temperature 34.2°.

AUTUMN NOTES ON VINES.

GRAPES, it is to be feared, will not keep well this winter. Being thoroughly matured before the short days set in is the most essential point to insure their preservation, but late Grapes I hear from many places are far behind in ripening, and in some instances they are actually refusing to colour. When this is the case with good Grape growers of extensive experience it is reasonable to suppose that amateurs and those with a limited knowledge of how best to assist the Grapes in ripening must now be labouring under considerable difficulty, and no doubt a few remarks on this matter and a few others relating to the autumn treatment of the Vine will be acceptable at the present time.

Grapes will colour as much in one week of bright weather as they will in three sunless weeks. Should the latter part of September and all through October turn out fine, as it is to be hoped they will, there is yet a chance of Grapes being in good keeping order by the beginning of November; but, on the other hand, if the weather does not at once make a change for the better artificial means must be resorted to, to make up for the want of sun heat; and although this will be both expensive and imperfect to a certain extent, it will be cheaper and more satisfactory than complete failure.

The best time to apply fire heat to ripen Grapes is during the day. In dull days raise the temperature to 65° or 70°, with a little air on at top and bottom. Let the fire go very low at night when the house is dark, and little air being admitted. When there is only a bright day once or twice a-week do not let the fire go out because it is fine, but, on the contrary, keep the fire as strong as on a dull day, give more air, and let the temperature rise to 80°, 85°, or 90°. This is the time they will colour quickly, and not only colour but flavour, which is more desirable than a fine appearance. Worked as above described it is surprising the progress Grapes will make towards maturity in three or four weeks. Of course when day after day is bright and warm it is unnecessary to use any fire heat. Then do not admit too much air. Always keep the heat up about 80° during the day, and close the ventilators early enough in the afternoon to maintain a temperature throughout the night of 65° or 70°. These are the best ways of working the heat, but other assistance may be given.

In the summer time when the Vines are growing fast and strong, the laterals are generally pinched at the first leaf. A shoot soon pushes away from this again, and very often it is not pinched back to this base again but at the next leaf, and when it is treated like this three or four times the laterals at this time are bearing more leaves than the principal rods, and running into one another they form a dense mass of foliage. This interferes very much with the air circulating about the fruit, and it also obstructs the light; and it does more, and perhaps worse than this—it prevents the bearing wood of

next year from becoming ripe. It will thus be seen that these lateral shoots may do much harm to the Vines after this time and should therefore be removed. To remove them early in the season when the wood is green and the sap flowing rapidly would give the Vines a severe check, and would probably produce shanking and other maladies; but now, when the wood is mostly hard and becoming ripe, I have never been able to see that taking off the side shoots did any harm to the Vine afterwards. Every one of our Vines were gone over like this the other day; both those with fruit and without it. Before, the glass could not be seen in many parts inside; now, the bunches can be seen looking in from the outside down through the leaves. Every berry is exposed to the light, and every inch of wood is the same. In our case the shoots were not removed so much to let the Grapes ripen as the wood. This, although brown and might be considered quite ripe by some, is still sappy; and I am a firm believer in ripening the wood to the fullest possible extent. This accomplished, let the wood be small or thick, next year's crop is secured.

Apart from giving the wood and fruit a better chance of ripening, cutting the laterals off now has another recommendation. It is well known that nothing condenses moisture so much as a thick covering of leaves against the glass or above the fruit. Grapes begin to damp now; when the foliage clusters round them it is impossible to prevent this, and much decay may be traced solely to this cause. When the leaves are removed the moisture which rises from underneath passes direct to the glass and runs down it without ever resting on the Grapes. When the Vines are so far advanced in ripening that the leaves are dropping, do not let them lie about the floor, but gather them with the hand every morning, and this will not only keep the house tidy, but the atmosphere sweet and free from moisture.

Where Vine roots are wholly in outside borders there is not much danger of the roots becoming dry—this year at any rate; but inside borders very often become dust-dry through receiving no water from the time the fruit begins colouring until it is all cut. I do not think it is wise to let the soil become so dry; Vines with their roots outside in wet borders just ripen their fruit as well and as finely flavoured as those dried off inside. Where borders have been kept dry, and the fruit now cut, give them a thorough watering at once, or many of the young fibrous roots will perish, the wood shrivel, and the leaves wither up prematurely.

These notes apply chiefly to work that must be done from now up to the beginning of November. By that time bedding and other plants will have been put into many vineries, and notes on what to do then will appear about that time.—A KITCHEN GARDENER.

THREE YEARS' EXPERIENCE IN A GREENHOUSE.

HAVING decided to build my house I set about it at once. Striking the iron while it is hot, is an old saying and a good

one; you work with so much more pleasure and energy when carrying out a new project on the spur of the moment.

I first called on several nurserymen in the neighbourhood and asked their opinions as to whether a span-roof or lean-to would be best, also should I build on the level or how much below. Adopting their suggestions, I decided to sink 18 inches and to have a span roof; firstly because you economise the heat and prevent a rapid evaporation by being somewhat below the surface, and secondly because a span roof is the only one under which to grow symmetrical plants. I was not very particular as to size—not, however, wishing to exceed about 12 feet by 9, so that in purchasing my lights for the roof I was easily accommodated. After a little searching I found and bought two glazed lights 11 feet by 4 feet 6 inches for £2 5s., a door in frame 10s., carriage 7s. 6d.

Now I had data to work upon; so I at once called in a bricklayer and a labourer, who dug out the necessary space and put up the walls, 4 feet in height by $4\frac{1}{2}$ inches thick, price £2 7s. 6d. Next I employed the village carpenter to work with me in making the side lights and ends, also to help me to put the whole thing together: his account with timber was £3 10s. Then I went at it alone, measured for the glass, and though I had never put in a pane in my life I determined to glaze it, having first asked someone to show me how to manipulate. I only had one minute's instruction. Well, I surmounted that difficulty much easier than I expected. Glass, putty, and knives, 17s.; paint (24 lbs.) and brushes, 12s. 6d.; timber for stages, 9s., which I put up in this way—three tiers on the north and a level stage on the south, leaving 2 feet 6 inches in centre for pathway. Dimensions when complete, inside 10 feet 6 inches by 7 feet 6 inches; 4-foot brick wall, 15-inch side lights.

Now came the knotty point, in fact several knotty points—how to heat, and with what to fill the house, &c., for I was so thoroughly ignorant on all matters connected with greenhouses, having spent most of my life travelling in Australia and China, that I had to work very much in the dark; but he who truly loves plants and flowers soon finds out the way to treat them successfully. In the first place I resolved not to make my greenhouse simply a storehouse for Geraniums, Fuchsias, and ordinary bedding plants, especially as I afterwards found that I could keep them well enough in a cold room, but to grow as many distinct and different varieties of flowers, Ferns, &c., as I could manage in the space at command that I might have a constant and increasing pleasure in watching the growth and development of beauty in various forms and stages, instead of the ordinary satisfaction of turning out a batch of Geraniums, Calceolarias, &c.

I procured a few *Adiantums*, *Primulas*, *Cinerarias*, cuttings of French *Geraniums* Dr. Andry, *Fulgens*, *Victor* and *Neptune*, a plant of *Pteroma elegans*, *Plumbago capensis*, six *Azaleas*, two *Camellias*, one *Aloe frutescens*, two *Acacias*, six *Cyclamens*, six *Cactuses*, one *Deutzia gracilis*, and two *Cytisuses*. These I thought enough for a start, though I afterwards became more ambitious. The selection of these plants was due partly to advice of friends, but mostly to that comprehensive little work "The Greenhouse," published at your office.

Autumn being far advanced I began to look about me for a heating apparatus, and after numerous inquiries I decided on a Roberts's patent terra-cotta stove, and saw one advertised, largest size with smoke pipe for 25s. I bought it, and I think on reckoning up the items you will find the entire cost for building, painting, heating, &c., amounts to about £12 15s. The stove I found effective but difficult to manage. It is most simply constructed, and the directions so plain that it seems impossible to go wrong. However, I managed it at last, and found very little trouble in keeping the heat up to 50° in the depth of winter without any fresh supply of fuel for from twelve to twenty-four hours, and I have even found it quite hot at the expiration of thirty-six hours. You must own it is worth a little trouble to arrive at this result when I tell you it only costs about £2 15s. to keep up quite the heat of a semi-stove house for eight months. One great drawback I had to contend with was the dry heat, which generated red spider on the *Azaleas*, shrivelled up the *Adiantums*, &c.; so after thinking it over I hit upon a plan which has proved invaluable. I procured a sheet of iron 2 feet by 2 feet punched with holes round the edges for nails; I then fixed together four pieces of wood 1 inch by 4, nailed on the iron plate, putting a piece of list between it and the wood—making, in fact, a shallow box with an iron bottom nearly watertight. I then half filled the box with sawdust, put in a

gallon of water, and placed the whole on the top of the stove. In less than a week the beneficial effect was plainly observable, indeed it proved a complete success.

It then occurred to me that this tray of hot moist sawdust might be still further utilised; so I placed on it according to season and requirements pots and pans of cuttings, *Verbenas*, *Heliotropes*, *Deutzias*, *Lobelias*, and many other things that will not readily germinate or strike when most required—namely early spring. Everything grew and rooted in a wonderfully short space of time. The plants were potted-off in 60's, returned to the tray for a week, then removed to narrow shelves swung with copper wire from the rafters so as to be close to the glass. The only fault I found was that they grew too quickly.

As to the management of the stove itself I feel constrained to give my fullest experience, the more especially as I know many who have entirely failed in its management. Indeed I called on a florist this morning to show him a new *Gloxinia* I had raised since March, and he asked how I heated. I told him. He was much surprised, as he had heard the stoves in question were complete failures. In the first place the stove is in three parts—stand or ashpan, body, and lid. I found the separation of the body from the stand to be a mistake, so had them cemented together. Then I had a 4-inch instead of the usual 3-inch smoke pipe: this causes a greater draught and obviates the necessity for sweeping, which operation is troublesome and dirty, besides being detrimental to the plants; whereas with the larger flue you have only to wait till the fire is well blazing, then with a few smart taps up and down the pipe the soot falls, catches fire, cleans the chimney, and gets the heat up at the same time. Close the dampers to a quarter of an inch, then in about an hour, or less if you find the stove heating regularly, shut them closely. Assuming that you light your fire at 8 p.m. you will under all ordinary circumstances find it still giving out sufficient heat at the same hour next evening. Now, as to lighting, a most important item. Fill the portable pan three parts with coal, then a piece of paper, then a good handful or more of dry wood (I use mine hot from the oven), on the top of that a good shovelful of fair-sized coals, and it is ready. For the sake of giving fuller information we will suppose you wish to change your fire, heat going down. This requires practice to prevent injury to the plants from fumes which must escape. First remove the tray of sawdust, then open the top ventilator; with a strong iron hook in hand take the top off the stove, lift out of the house the exhausted pan, pop in the fresh one, throw in a match on the paper, put on the lid, shut the ventilator, and the whole process is finished in less than a minute; then you have nothing to do but regulate the dampers as above advised. All this may appear very simple, but it took me at least six months to find out the right way to manage the thing effectively. This is only my first year's experience, but it was practical, and acting upon it I made many improvements the second year.—*RESPICE FINEM.*

STRAWBERRIES—SOIL—SORTS.

Most gardeners will agree with me that much so-called Strawberry culture is unworthy of the name, is just a mere manuring of the soil, planting of the plants, watering, weeding, and cutting off runners—the ordinary routine in point of fact, without any attempt to find out if the soil itself requires any special treatment to render it suitable for the production of fine fruit: hence, therefore, this outcry about sorts and soils so calculated to mislead that it cannot be left unnoticed.

On page 148 I stated that "all kinds grow strongly and bear fruit abundantly in a rich loam, or in soil that is brought by cultivation as nearly as may be into a similar condition to it." I repeat the statement here, and challenge anyone to refute it. "AMATEUR, Cirencester," says I go a little too far, or to put it in other words, am a little too positive about this matter, quoting Messrs. Rivers, Darwin, and Beaton to prove it. Now these are the names of good men and true. All honour to them! Their words have not been lightly spoken. What say they? Darwin: That "successful culture of British Queen depends upon the condition of the soil." Beaton: That "to grow British Queen at Shrubland the whole nature of the soil must be altered." Rivers: That "Eliza does not thrive except upon a chalky soil." I do not, therefore, hesitate to claim the two first of these great authorities as being clearly on my side, and am able to assert from my own experience that splendid crops of *Eliza* have been produced by plants growing in soil without any perceptible traces of chalk,

which Mr. Rivers will doubtless be glad to know as tending to prove the greater usefulness of his valuable seedling.

If climatic influences were in question I might agree with the teaching which points to certain localities for certain sorts, but that is clearly not the question; it is simply one of soils, all of so pliant a nature as to be susceptible of any improvement or change, and I submit that to regard such a simple matter as an insuperable difficulty is not only wrong but decidedly mischievous. Such obstacles we must expect to encounter and resolve to overcome. To those who think the doing so is likely to prove costly or difficult let me recommend a second perusal of a paper by "ESSEX" on page 170; it abounds with good sense, and enforces better than any argument could do the perfect results attending an intelligent method of culture.

More fault has been found with British Queen and Dr. Hogg than with any other kinds—not about the quality of the fruit, for that is so excellent as to be above criticism, but about growth and crops. Has the fact that both of them, like certain other high-class fruits, require that high culture of which they are so worthy, not yet obtained that clear recognition which it merits? It is many years ago that I was taught this lesson—taught it too by a pupil of my own whom I had taken from the plough, and who is now gardener to a Marquis. In a garden which I sent him to take charge of, and where I in really good soil had had crops of British Queen of only medium excellence, he by superior culture had subsequently abundant crops of magnificent fruit. All kinds of Strawberries like sewage, or in fact any liquid manure; those of the British Queen type will not perfect their fruit without it, the yellow hard-tipped fruit affording as distinct an indication of starvation as do the pinched features and attenuated limbs in a human being. Give liquid manure plentifully to the Strawberry, and, other things being equal, you may have abundant crops in pots as well as in the open ground of fruit full-sized and superior in every respect.

Surely it is somewhat premature to pronounce the new kinds *Exquisite* and *Traveller* as "capricious, only doing well in certain seasons and places," as somebody has done in reply to my recommendation of them. Perhaps the best answer I could make would be to inquire, For how many seasons have these novelties been tried, and in the hands of how many clever men? My opinion rests solely upon what I saw and tasted in a single garden where they were growing side by side with some dozens of other sorts new and old, and there I was so much pleased that I intend growing both of them. I may add that both the gardener and his employer thought much of them, and letters have come to me from other quarters all speaking highly of them. Will my critic tell us why they are capricious, and in what places, or rather soils, they do not answer, and thus afford us a hint which may prove more useful than a mere vague stricture can do?—EDWARD LUCKHURST.

THUJA OCCIDENTALIS.

THIS, the American *Arbor-Vitæ*, makes a capital hedge, and is well suited for many positions, especially where not exposed to strong gales of wind. It answers better in partially shaded places than many other shrubs do, and with those who understand its nature and the kind of treatment necessary to make it accommodate itself to certain positions very pleasing screens may be formed to hide unsightly walls. I have seen such screens, and have dressed some of them. For hedges of this shrub to have a pleasing appearance they should never be clipped with the shears, as by doing so you give them a stumpy appearance, which it is desirable to avoid.

This *Arbor-Vitæ* is employed in many nurseries to form screens for giving shelter to plants while they are in a young and tender state, and for this few shrubs are better adapted when judiciously managed. They can be kept very thin and green down to the ground for many years, while they are devoid of that stiff and shorn appearance which most hedges have. They occupy very little space, and to prevent their roots spreading out them with a spade at about a foot or 15 inches from the stem. By doing one side one year, and then the other side the following year, the roots will be kept from impoverishing the ground or from injuring young plants which may be near to them. When planted against walls the leader and main branches as they grow up should be fastened to the wall by means of iron staples passing round them and into the wall. When the *Arbor-Vitæ* is judiciously managed in such a position, and having all the unnecessary breastwood cut off with a knife, it can be managed so that it may retain a graceful and

Fern-like appearance, which is especially pleasing when the wind ruffles its feathery sprays; indeed, under the management of a person who understands how to train and manage the *Arbor-Vitæ*, it is so accommodating that it can be turned to many useful and ornamental purposes.—G. DAWSON.

WORTHY NOTES AND SUGGESTIONS.

I REALLY must thank my friends S. Reynolds Hole and the "HEREFORDSHIRE INCUMBENT" for their very kind allusions to me. It was a great trial to me not to be well enough to be present at the great Rose contests of the present year. I must hope that our great authority on Roses, great I may say in both senses of the word (and "may his shadow never grow less,") may in the end prove me wrong about Cheshunt Hybrid. He knows, however, I am somewhat firm (obstinate, some people call it) in my opinion, and till I see a better bloom than I have hitherto seen, all its growth and its efflorescence and the fact of its being a hybrid with a certain indefinite proportion of Tea in it, will not make me alter my opinion that as an exhibition Rose it is only second-rate, and that before many years are over it will gradually decline in its position as certainly as *Marquise de Castellane* and *Etienne Levet* will advance.

I agree with my old friend S. Reynolds Hole, it is certainly bountiful, I only question whether it is most beautiful; and as he knows, I do not like to differ from him in opinion. I am obliged to confess, though I have a great hankering after other flowers, notably for *Gladioli*, and *Phloxes*, and zonal *Geraniums*, and tuberous-rooted *Begonias*, that after all a really good Rose carries off the palm. I only wish her majesty the queen of flowers was less at the mercy of seasons; or, perhaps I might say, that we gardeners were less at the mercy of the elements under such a season as the present. Here we have not had forty-eight consecutive hours without rain since the 4th of July, and the average rainfall of each week has been over an inch. Roses like *M. Noman* and *M. Lacharme* glue-up their petals and rot in the buds. None but the hardiest with the firmest petals and best outer guards—i.e., good, well-developed outer petals, could stand the weather.

To show the backwardness of the season, *Sedum Fabaria* or spectable on a warm border facing south is not yet nearly in bloom, and on a rockery with south-east aspect will not be in bloom for two or three weeks. We have always a harvest festival. Three weeks ago we issued a programme or schedule for a small cottagers' and agricultural exhibition as an accompaniment to the festival. Last night (September 14th), in torrents of rain we, the Committee, met to try and decide upon a day, but the unanimous opinion was that it required at least a fortnight or three weeks of fine dry weather before we could fix upon a day for a harvest thanksgiving at all, and that possibly we might see again, what I saw in 1860, a field of Wheat uncut on the 12th or 13th of November. This certainly is not florists' weather any more than farmers'.

I am glad "*WYLD SAVAGE*" has raised his voice against the very inadequate prizes often offered by so-called horticultural societies, and the impediments they too often offer for exhibitors. What would the *Savage* think of 6s. offered as a first prize for three *Begonias*, when each plant shown was worth at least £2 or £3, and were quite as valuable as the three stove and greenhouse plants for which a prize of 30s. was offered? However, there were the usual acrobats, and a very fat slack-rope dancer, who proved too much for the wire, which gave way under her lucubrations. I dare not, as "*WYLD SAVAGE*" does, mention names, but I certainly wish with him that horticulture proper was properly represented in these country shows, instead of acrobats improper with all their accompaniments. I do not like going to a cricket match to see it burlesqued by a parcel of clowns dressed-up in fancy costumes, and who say you "flupid stool," instead of you "stupid fool," if anyone misses a catch or has the misfortune to get bowled-out; but it is even worse to see a good horticultural show gradually decaying into a second-rate exhibition of acrobats, clowns, and fireworks at night, and the tents deserted to look at an overdressed female, or underdressed as the case may be, exhibiting her prowess on the stage.

One word more to the *Savage*. I thought his request of a list of herbaceous perennials to grow in a border, if I remember right about 50 feet by 7, would bring him a list as long as his arm. I know I am prejudiced, but I cannot see why every possible variety of perennial should be crammed into a perennial border, any more than that I should grow every possible

variety of weed in a quarter of my kitchen garden in order to study and admire the picturesque growth of weeds. Only a certain quantity of perennials can be properly grown in a border such as he names, and a few of the best varieties of each sort will give him infinitely more pleasure than a conglomeration of all the herbaceous plants, which (to use the accustomed phrase), ought not to be omitted in a collection of perennials. Good Phloxes, Pentstemons, Gladioli, Delphiniums, Antirrhinums, and Dianthus in their different classes will give him far more bloom and far more satisfaction than the endeavours to grow about forty or fifty species in a limited space. Of course this is only my doxy, and may be heterodox, but as such I venture to put it forward.

I do not think there is any royal rule as to time in planting Roses which the "HEREFORDSHIRE INCUMBENT" alludes to, but there is and always will be a state of rest for Roses, unless as last year a very open autumn be followed by an open winter, and afterwards a cold spring and wet summer. Under such conditions it is difficult to say when the wood is ripe enough or the plant sufficiently matured to bear removal; but I fully believe on the whole it is better to be too early than too late, and if not done before the Yule log appears on the scene it is better to defer it till the end of March or the beginning of April, when the plant will commence its growth at once. A very dry May or June will even then upset all calculations; but I think it is better to mulch than to water, and frequent ablutions only lead to surface-rooting and the necessity for further applications. I am in hopes "HEREFORDSHIRE INCUMBENT" will reap another year the fruits of his over-manuring, and that his kindness to his plants will not be thrown away.—C. P. PEACH.

THE POTATO DISEASE.

MR. ADDISON says that no one shall make him believe that the disease did not exist previously to 1846. That certainly is the year when it made its first great ravages; black or decayed Potatoes of course there always were the same as we now find in other roots after being stored a time, but can any one state well-authenticated cases of the true disease being found at the digging-time previously to 1846?

What Mr. Addison says about storing and sprouting being the chief cause of the disease is open to doubt. I have Ash-leaved Kidneys now that for years have been taken the greatest care of, only being allowed to sprout in boxes and then planted, but in a late, wet, sunless season like the present they have taken the disease badly.

The theory of Potatoes wearing-out and becoming more liable to disease has two sides. You may renovate their constitution by growing them occasionally on new land, but you cannot prevent their taking the disease. I have grown the old Fortyfold and Dalmahoy this year on some poor black sandy soil from which a Fir plantation of over forty years' growth was taken down last winter. It was a splendid crop, but three-fourths diseased. The disease could not have existed in the soil. Can anyone tell us what is the true cause of the Potato disease?

I certainly do not wish to differ with such an authority as Mr. Abbey, but he says it should be made imperative to separate the diseased from the undiseased tubers: that is what I suppose most people do. If you take some diseased Potatoes, not rotten ones, and lay them up very dry till spring, and plant them, they will produce good Potatoes not more liable to disease than others; and even at this time of year or a little later, among the stored Potatoes you will find sometimes a bad one that has commenced producing small good tubers. Some few years ago I had a plot lifted that just began to show the disease; they were graven not very thick for a short time, but wet weather and a press of other matters prevented their being looked over for three weeks, when they were found to be nearly all decayed. They were stored on the same plot they grew on. After a rain a few good tubers were picked-out and the others dug-in. The following year, for experiment, I planted a portion with Potatoes again. A dry hot summer followed, and I had a fine crop with very few bad Potatoes among them, and I remarked how strong and dark the foliage was.

There is, I think, a great connection between the Potato disease and electricity. I have noticed for years that you may first see it after a thunderstorm. This year we had thunder very early—I think the beginning of March. My frame Potatoes took the disease very shortly after, and on Good Friday

morning I could scarcely take a dish of good tubers from a whole frame. Now that was not brought on by either wet, or cold, or drought, because in a pit you can keep them as you like, but the electricity seemingly developed it. Of course, in many seasons you do not see a bad one in a pit or frame, but if the germ theory be correct it would be present one time as well as another. Sutton's Flourball this season stands its ground well, being nearly free from disease, and mine were not treated with salus either; and if anyone can raise a disease-resisting Potato like Sutton's, earlier in its habit and of more uniform quality, and as good a cropper, he will be a benefactor, and I think would acquire a fortune; for the climate has not enfeebled that yet, as is the case with others, such as American Rose, Snowflake, &c., which seem to have taken the disease as badly as any others this season.—JOHN PLATT, *Hillington*.

CRYSTAL PALACE SHOW.

SEPTEMBER 21ST AND 22ND.

MANY excellent autumn exhibitions have been held in the colossal structure at Sydenham, but it is questionable if any have been superior to the twenty-second Show, which opened on Friday last. Third prizes were wisely included in the schedule, a circumstance which no doubt contributed materially to the extent of the display. The Show occupied the whole of the north nave. The central table was decorated with Palms and other ornamental-foliaged plants. On this table the collections of fruit—Grapes (upwards of three hundred bunches), Peaches, Plums, Figs, Melons, Apples, &c.—were arranged. One of the side tables was chiefly occupied by Dahlias, an extensive and superior display; also Asters, Gladioli, and Roses. The other side table contained splendid collections of vegetables, the finest which have been seen for many a day; also miscellaneous collections of fruit, remarkably fine contributions of Roses, and an admirable selection of Gladioli. But although the Exhibition is unhesitatingly pronounced an excellent one it contained nothing particularly sensational; and on the other hand—and this constituted its chief merit—nothing, save perhaps a few inferior Grapes, that was not creditable to the several exhibitors. Thus much of the Show generally, and now to the classes, commencing with

FRUIT.

COLLECTIONS.—Class A was for a collection to consist of twelve dishes, two each of Pines, Grapes, and Melons being permissible, the remainder being single dishes. There were three competitors, the redoubtable Mr. Coleman, gardener to Earl Somers, Eastnor Castle, securing the foremost place. He was several points a-head of his rivals Mr. Webb, gardener to J. H. Manners Sutton, Esq., Burton-on-Trent, who had the second prize, and Mr. Upjohn, gardener to the Earl of Ellesmere, Worsley Hall, Manchester, who was placed third. Mr. Coleman's collection contained splendid Black Hamburgh and Muscat of Alexandria Grapes, medium-sized Black Jamaica and fine but unripe Smooth Cayenne Pine Apples, handsome Golden Gem and Eastnor Castle Melons, very large Pitmaston Duchess Pears, and capital dishes of Morello Cherries, Barrington Peaches, Pitmaston Orange Nectarines, with Green Gage Plums and Brown Turkey Figs of moderate quality. The most noteworthy fruit in Mr. Webb's collection were a pair of splendid Queen Pines weighing 5½ and 5¼ lbs. respectively. These fruit won him the second honours, Mr. Upjohn's Pines being rather small, but his other dishes, Grapes especially, and Melons, Peaches, Figs, &c., were of excellent quality. It did not state in the schedule that the Pines should be dissimilar, neither, indeed, was it specified that the Grapes and Melons must be distinct varieties. It is advisable that the conditions in this respect should be clear and definite. In the class for six dishes, distinct, exclusive of Pines, there were only two competitors—Mr. Neighbour, gardener to G. Wythes, Esq., Bickley, Kent, who was placed first; and Mr. Taylor, gardener to J. Johnstone, Esq., Upper Terrace House, Hampstead Heath, who had the second prize. Mr. Neighbour exhibited good Black Hamburghs and rather thin bunches of Muscat of Alexandria Grapes, a capital Scarlet Gem Melon but not quite ripe, fine Pine-Apple Nectarines also unripe, good Violette Hâtive Peaches, and Magnum Bonum Plums. The Grapes were the weak point in the second-prize collection, the other dishes being in equal if not better condition than Mr. Neighbour's.

GRAPES.—In the class for ten kinds, two bunches of each, Messrs. Lane & Son, Great Berkhamstead, and Mr. Wildsmith, gardener to Viscount Eversley, Heckfield, were the only exhibitors, and were placed in the order of their names. Messrs. Lane staged Mrs. Pince's Black Muscat, full and good but not well coloured; Gros Colman, extra fine; Foster's Seedling, rather small; Bowood Muscat and Muscat Hamburgh, excellent; Trebbiano weighing about 5 lbs., Black Alicante about 3 lbs., Muscat of Alexandria about 4 lbs., and Black Hamburgh and

Black Prince also very good. Mr. Wildsmith staged good examples of Black Hamburgh, Alicante, White Tokay, Foster's Seedling, and Mrs. Pince well coloured; the remainder were small. In the class for five kinds, two bunches of each, three collections were staged; Mr. Woodbridge, The Gardens, Syon House, winning first honours with medium-sized bunches but level and fresh of Madresfield Court, Golden Champion, Lady Downe's, Muscat of Alexandria, and Alicante. Mr. Peed, Roupell Park Nursery, Norwood, had the second place with larger bunches, but some of them were shrivelled and worn, although Gros Colman, Alicante, and White Tokay were good. Quality fairly beat size in this class. Mr. Bolton, gardener to W. Spottiswoode, Esq., Combe Bank, Sevenoaks, had the third prize.

In the class for three bunches of Black Hamburgh there were twelve competitors, some of whom staged excellent produce so far as regards shape of bunches and size of berries, but only one exhibitor staged really black and well-finished examples—Mr. Coleman, who had the third prize, the berries being small in comparison with those of Mr. Adams, gardener to Rev. Mr. Hudson, Frogmore Hall, Hereford, who had first honours with bunches of faultless shape and remarkably fine berries but deficient in bloom. Mr. Wildsmith had the second prize with very good examples and fairly well coloured. In this class size, to the surprise of many Grape growers, triumphed over high finish. It was a difficult class to judge, Mr. Adams' fruit being so fine and Mr. Coleman's so well coloured but small. A few very poor bunches were staged. Mr. Coleman won easily in the Muscat of Alexandria class with good bunches, about 3 lbs., and splendid berries. Messrs. Lane & Son were second with five or six-pounders, but rather irregular; and Mr. Day, Norton Hall, Daventry, third with medium-sized bunches and fine but not highly finished berries. Mr. Hollingworth, Turkey Court, Maidstone, Mr. Davies, Chelmsford, and Mr. Pepper, Bromley, exhibited well in this good class.

Mr. Earp, gardener to J. S. Sellon, Esq., Home Towers, Bournemouth, won the premier place in the Madresfield Court class with rather small bunches and berries, but excellently coloured and finished. Mr. Woodbridge was second, and Mr. Ridout, gardener to J. B. Haywood, Esq., Woodhatch Lodge, Reigate, third with much finer produce, but not well coloured. In this class quality won. In the Hamburgh class size prevailed. Mr. Stephenson, gardener to F. Peed, Esq., Roby House, Sydenham; Mr. Miles, Wycombe Abbey; and Mr. Toomer, gardener to W. Knowles, Esq., Streatham, were placed in the order of their names with Foster's Seedling. The berries were generally small, and the class of six competitors a rather weak one. A better display was made in the next class—Lady Downe's, where Mr. Tyler, gardener to R. Gosling, Esq., Bishop Stortford, won with medium-sized bunches, the berries and finish being very good. Mr. Coleman was placed second with small bunches but fine and excellently coloured berries, and Mr. Neighbour third. Mr. Kneller, Malshanger Park, staged very fine produce but not fully ripe, yet worthy of an extra prize. There were ten competitors. Six lots were staged in the Buckland Sweetwater class, but some of them were very poor, and the winning stands only moderate. Mr. Bungay, gardener to W. Smith, Esq., Herne Hill, Dulwich, was placed first; Mr. Beesley, gardener to R. Jones, Esq., Clapham Common, second; and Messrs. Lane & Son third. In the class for three bunches of any other kind there were sixteen competitors, and the excellence of the produce gave the Judges some trouble in making their awards. Messrs. Lane & Son were placed first for splendid Alicantes, weight about 3 lbs. and highly finished; Mr. Perks, gardener to C. W. Dusseldorff, Esq., Dorchester House, Sydenham, second with excellently finished bunches of Gros Guillaume about the same weight; and Mr. Peed, Roupell Park, third with good Alicantes—a capital class. The class for the heaviest bunch of any kind brought out eight competitors, but some of the bunches, as one of the Judges remarked, were as "ugly as sin." Mr. Dickson, gardener to J. Jardine, Esq., Arkleton, N.B., the renowned northern grower, easily won the first prize with, for him, a small and fairly good bunch of Syrian weighing 10 lbs. 10 ozs.; Mr. Peed was second with Gros Guillaume, 5 lbs. 8 ozs.; and Mr. Tyler third with a bunch weighing 5 lbs. 4 ozs. While this class is retained in southern schedules we must again note the omission of a class which is well responded to in the north—namely, for superior quality and high finish, the bunches not to weigh less than 1 lb. A class of this nature is well worthy of trial at the southern shows. In the miscellaneous class an extra prize was worthily awarded to Mr. Mowbray, gardener to the Earl of Leven and Melville, Fulmer, Slough, for a small but very full and regular bunch of Golden Champion. The berries were of great size, well finished, clear, and spotless, and reflected much credit on the grower. A good and fairly finished bunch of Gros Guillaume from Mr. James Lovey, gardener to G. Dixon, Esq., Gothenburgh, Sweden, was noticeable, considering the high northern latitude in which it was grown. The prizes offered by Mr. J. B. Pearson for Golden Queen were not awarded. A few bunches were staged, the best being from Messrs. Lane & Son, but they

were not considered of sufficient excellence to merit the rewards provided.

PINE APPLES.—Eighteen fruits were staged, some of them very fine, and none unworthy of the place they occupied. Mr. Webb won the premier prize in the class for Queens with a grand fruit weighing 6½ lbs. Mr. Day, Hillside, Newark, was placed second, weight of fruit 5 lbs. 1 oz.; and Mr. Miles third with a handsome well-conditioned fruit weighing 4½ lbs. In this class Mr. Lee, gardener to T. King, Esq., the renowned "Tom King" of history, exhibited a capital Queen weighing 4 lbs. 14 ozs., which had been grown in an 8-inch pot. In the class for any other variety Mr. Ross, gardener to C. Eyre, Esq., Welford Court, Newbury, had the premier place with Smooth Cayenne weighing about 6 lbs.; Mr. Pragnell, gardener to G. B. W. Digby, Esq., Sherborne Castle, Dorset, being placed second, weight 5½ lbs.; and Mr. Sandford, gardener to the Earl of Bective, third, weight of fruit 5 lbs. It was the best exhibition of Pines of the year.

PEACHES AND NECTARINES.—Eighteen dishes of Peaches were staged and fifteen dishes of Nectarines, nearly all of which were good, a few, however, being deficient in colour. Mr. Gibson, gardener to T. F. B. Atkinson, Esq., Halstead Place, Sevenoaks, was placed first in the class for Peaches with a dish named Lord Palmerston, which was certainly not correct; it was more like the yellow-fleshed American variety Crawford's Early. Mr. Frost, nurseryman, Maidstone, was second with Barrington; and Mr. J. Fry, gardener to L. J. Baker, Esq., Haydon Hall, Pinner, third with Princess of Wales. **Nectarines.**—Mr. A. Jameison, gardener to the Earl of Crawford, Haigh Hall, Wigan, gained the first prize with Prince of Wales, very good. Mr. S. Bolton, gardener to W. Tipping, Esq., Brasted Park, Sevenoaks, was second with Hunt's Tawny; and Mr. W. Cox, Madresfield Court, Great Malvern, third.

MELONS.—A rather extensive collection was forthcoming, several of the fruits being well shaped and netted, and were attractive in appearance. Twenty scarlet-fleshed and twenty-eight green-fleshed fruits were submitted to the Judges. Many of the Melons were of inferior flavour, and it was only after much and careful deliberation that the prizes were awarded. In the Scarlet-fleshed section Mr. Oliver Goldsmith, Polesden Lacey, Dorking, was awarded the first prize for Scarlet Gem; Mr. Coleman, Eastnor Castle, the second for Read's Scarlet; and Mr. Kneller, Malshanger Park, Basingstoke, third for Hero of Bath. In the Green-fleshed class the first prize was awarded to Mr. R. Adams, gardener to the Rev. T. D. Hudson, Frogmore Hall, near Hereford, for a "seedling;" the second prize to Mr. Coleman for Eastnor Castle, and the third to Mr. John Day, Norton Hall, Daventry.

PLUMS, CHERRIES, AND FIGS.—Plums.—The class for three dishes, distinct, six fruits of each, was represented by eight competitors. Mr. James Bolton was awarded the first prize for Golden Drop, Jefferson's, and Pond's Seedling. Mr. Staples, gardener to H. Oppenheim, Esq., Chipstead Place, Sevenoaks, second with Magnum Bonum, Pond's Seedling, and Golden Drop; and Mr. Fry, gardener to L. G. Baker, Esq., Haydon Hall, Pinner, third with Transparent Gage, Belgian Purple, and Jefferson's. Only two collections of Green Gages were exhibited. Mr. James Fry and Mr. W. Hall, gardener to W. Stevens, Esq., Springfield, Tulse Hill, were placed first and second respectively; and for a dish of any other kind the first prize was awarded to Mr. Staples for Coe's Golden Drop; second to Mr. J. Walker, nurseryman, Thame, Oxon, for Pond's Seedling; third to Mr. James Bolton for the same variety; an extra third prize was awarded to Mr. James Fry for a very fine dish of Transparent Gage. There were fifteen competitors in this class.

FIGS were remarkably fine, especially the first, second, and third-prize dishes, and to mark the excellence of the collections staged, of which there were twenty-four dishes, the Judges awarded two extra prizes. Mr. John Burnett, gardener to Mrs. Hope, The Deepdene, Dorking, was first with White Marseilles; Mr. W. Divers, gardener to W. Moore, Esq., Maidstone, second with Brown Turkey; Mr. W. Chisholm, gardener to R. C. Taylor, Esq., third also with Brown Turkey; extras to Mr. W. Chard and Mr. Rutland, gardener to the Duke of Richmond.

CHERRIES.—Mr. Thomas Jones, The Gardens, Elvetham Park, Wingfield, Hants, was placed first; Mr. T. N. Penfold, gardener to the Rev. Canon Bridges, Beddington, second; Mr. John Day, Norton Hall, third; and Mr. Miles, gardener to Lord Carington, extra third, all showing very fine Morellos.

APPLES AND PEARS.—Although the competition in the classes was not great, some splendid fruit, especially of kitchen Apples, was staged, and some large miscellaneous collections aided to make this section of the Show imposing. In the class for dessert Apples, three dishes distinct, six of each, there were four collections staged, and the first prize was awarded to Mr. Haycock, Barham Court, Maidstone, for excellent dishes of Ribston Pippin, Cox's Orange Pippin, and Melon Apple. Mr. Rutland was placed second for very fine King of the Pippins, Ribston Pippin, and Webb's Seedling; and Mr. Ross, Welford

Park, third; an extra third was awarded to Mr. J. Bolton. For three dishes of kitchen Apples there were the same number of competitors as in the previous class. Mr. Bowles, gardener to W. Skinner, E-q., Maidstone, gained the first prize with very fine Warner's King, Lord Suffield, and Stone Apple or Mapson's Seedling, very fine; Mr. Rutland the second for Warner's King, Lord Suffield, and very fine Blenheim Orange; Mr. Bailey, Amersham, third; extra thirds were awarded to Messrs. J. C. Goldsmith, Roots, and G. Goldsmith. Pears, three kinds, six of each, fifteen collections were staged. First, Mr. George Goldsmith, gardener to P. C. Hardwick, Esq., Holladen, Tonbridge, with Bauré d'Amans, Williams' Bon Chrétien, and Duchesse d'Angoulême; second, Mr. John Staples; third, Mr. Haycock; and extra thirds to Mr. Holden, gardener to W. Balston, Esq., Springfield, Maidstone, Kent; and Mr. James Dean, gardener to S. W. Gower, Esq., Titsey Park, Limpsfield. Extra prizes were awarded to Mr. T. Jones, The Royal Gardens, Frogmore, for thirty-six varieties of Pears and sixty varieties of Apples, excellent; to Mr. W. Paul, The Nurseries, Waltham Cross, for a collection of 120 dishes of Apples, a fine display; to Mr. Rutland, gardener to the Duke of Richmond and Gordon, for one dozen Calabrese Pears, very fine; to Mr. W. Wildsmith for twenty-five dishes of Pears and Apples; to Mr. L. A. Killick, Mount Pleasant, Langley, Maidstone, for a collection of one hundred varieties of Apples and Pears; to Mr. C. Ross, gardener to C. Eyre, Esq., Wilford Park, Newbury, for a fine collection of Apples and Pears, about seventy dishes; and to Messrs. Paul & Son, The Old Nurseries, Cheshunt, for an admirable collection of Apples in sixty varieties. Mr. Sleet, gardener to Mrs. Bailey, Norwood, also exhibited a good collection of twenty-four dishes of Apples.

Other extra prizes for fruit were awarded to Mr. G. W. Jobson, gardener to W. H. Stone, Esq., Herne Hill, for three Queen Pine Apples; to Mr. C. Haycock, Barham Court, for a good collection of Peaches, Nectarines, and Oranges; and to Mr. J. Peed, Rouppell Park Nurseries, for Vines in pots. Mr. Davy, gardener to J. Drew, Esq., Streatham, also exhibited creditable Vines bearing ripe fruit. Amongst other noteworthy exhibits we observed some very fine examples of Marie Louise, Doyenné du Comice, and General Tottleben Pears, which had been grown in Sweden and exhibited, with a bunch of Grapes above noticed, by Mr. Lovey. An attractive collection of twenty-four dishes of Tomatoes were exhibited from the Royal Horticultural Society's Gardens, Chiswick. The finest red was the "Old Red," the smoothest Hathaway's Excelsior. The best yellow was Carter's Green Gage—a very attractive collection.

CUT FLOWERS.

In ordinary years to have looked for a good show of cut flowers in London on the 20th of September would have been "a mockery, a delusion, and a snare;" but this has not been an ordinary year. All through the various seasons everything has been from a fortnight to three weeks late, and therefore not only were cut flowers shown in considerable quantities but also in excellent condition. The show of Dahlias, for instance, was not perhaps quite so extensive as we have seen it at the Palace, but probably a better lot of flowers was never staged, and it was a pleasure to find not only the veteran of Salisbury coming out in grand style, but that Mr. Turner is again entering the lists, and the Messrs. Rawlings of Romford occupying a prominent place, Mr. G. Rawlings having until very recently only exhibited seedlings. The terrible season in Scotland hindered the Scotch growers of Gladioli from competing. Messrs. Kelway & Son were, however, there in full force with splendid blooms, and there were other exhibitors, of whom more anon; and Asters were shown in beautiful order, while Roses were really grand for the season. There is evidently an attachment amongst horticulturists to the Crystal Palace, for the prizes were not large, yet they sufficed to bring together a considerable number of exhibitors.

In the class for forty-eight Dahlias the first prize was awarded to Mr. J. Keynes for a splendid box containing fine blooms of Henry Walton, Masterpiece, H. Glasscock, Seedling, Matilda, Perfection of Primroses, Dauntless, John McPherson, Vice-President, A. Oramond, Seedling, Herbert Turner, Thomas Goodwin, Criterion, Ethel Newcombe, J. N. Keynes, Rev. J. B. M. Camm, Queen of Beauties, J. Boston, Charles Leicester, Picotee, John Bennett, Queen's Messenger, Hon. S. Herbert, Seedling, John Standish, Cremona, James Service, Henry Bond, Mrs. Harris, Burgundy, Prince Arthur, Willie Eckford, Eccentric, Flag of Truce, Royal Queen, J. W. Lord, Prince of Prussia, Simon Neate, Flora Wyatt, John Wyatt, and Mrs. J. Downie. No finer box of Dahlias has ever been shown than this. Messrs. Rawlings, Bros., of Romford, were second with a very fine box. Conspicuous amongst the blooms were Baron Taunton, Acme of Perfection, Earl of Beaconsfield, and Countess of Pembroke. Mr. Charles Turner was third. Amongst his blooms the most noticeable were Mrs. Stoncomb, Miss Pressly, Toison d'Or, Silvia, Grand Duchess, Tiffany, and Barmid. In the class for twenty-four fancies Mr. Keynes was again first with a grand stand of the following:—Rev. J. B. M. Camm, Maid of Athens,

Herbert Purchas, Mrs. Sanders, Parrot, Letty Coles, Richard Dean, Mons. Chauvesse, Carnation, Fanny Sturt, Laura Haslam, Robert Burns, Henry Glasscock, Miss L. Large, Tippy Bob, Flora Wyatt, Hercules, Octoroon, Eccentric, Lucy Wyatt, Enchantress, Miss Bond, Samuel Bartlett, and a seedling. Mr. Seale of Sevenoaks was second, and Mr. C. Turner third. A large number of stands were shown by amateurs, and many of them in very fine condition. It would hardly be possible to find a finer twelve than those exhibited by Mr. Glasscock, for which he was awarded first prize; they were Henry Walton, James Cocker, Mrs. Harris, Thomas Goodwin, Ovid, Flag of Truce, Willie Eckford, Queen's Messenger, Prince Arthur, J. N. Keynes, Mrs. Standish, and Rev. Dr. Moffatt. Second prize went to Mr. Fewkes, Tyburn, Erdington, near Birmingham; and third to Mr. Slack, Queen Street, Chesterfield. In fancies Mr. Glasscock was again first with Mr. H. Glasscock, Miss L. Large, John Lambert, Flora Wyatt, Galatea, Parrot, Letty Coles, Queen of Spots, Grand Sultan, Viceroy, and Miss Boyd. Mr. W. Steer, Pope Street, Eltham, won second; and Mr. Fewkes third.

Of Asters there was a fine display, and I never remember to have seen finer French Asters than those exhibited by Messrs. Saltmarsh of Chelmsford; while Mr. Betteridge's Quilled Asters amply sustained his well-earned reputation as the first grower in England. In twenty-four French Asters Mr. H. Saltmarsh was first; Mr. John Morgan, gardener to Major Scott, Wray Park, Reigate, second; Mr. Lewis Morgan, Doods Road, Reigate, third. In twenty-four Quilled or German Asters Mr. Betteridge was first, Mr. Wheeler of Warminster second, and Mr. Gilkes third. In twelve Asters Mr. Brown was first, Mr. John Morgan second, and Mr. Lakin of Chipping Norton third.

Have Roses ever been shown in the month of September so good as on this occasion? I do not remember ever seeing such a box as that of Mr. Corp's at this season; not only were the Roses large and fresh, but they were every one of them in *character*, so that there was no difficulty in determining what they were. Messrs. Paul & Sons' and Mr. Harrison's of Darlington were also very fine, but Mr. Corp's was a long way ahead, and is another triumph for the seedling Briar as affording late blooms. But it must be remembered that these were cut from maidens. They were (twenty-four trebles) Marquise de Liparis, Louis Van Houtte, Camille Bernardin, Maréchal Niel, Sénateur Vaisse, Comtesse de Serenyi, Niphetos, Madame Charles Wood, La France, Etienne Levet, Marie Baumann, Marie Van Houtte, Paul Neyron, Sir Garnet Wolseley, Madame Victor Verdier, Capitaine Christy, Prince Camille de Rohan, Devienne Lamy, M. Alice Dureau, Pierre Notting, Baronne de Rothschild, Alfred Colomb, Emilie Hausburg, and Mons. Boncenne. Messrs. Paul and Son were a good second; and Mr. Harrison, or rather his representatives, third with a good boxful of too full-blown flowers, with probably the best treble of Madame Willermoz ever shown.

In Gladioli the place of honour must be given to Messrs. Kelway & Son, who exhibited a stand of thirty-six blooms of their own seedlings of surpassing excellence; the flowers were all large, the spikes grand, and the colouring fresh and bright. Conspicuous among them were Duchess of Edinburgh, a lilac-rose flower of great excellence; the other varieties were also splendid. This stand was not exhibited for competition. In the class for thirty-six Mr. George Wheeler of Warminster was first. Amongst his flowers there were a large number of seedlings and some good spikes of named flowers, especially Adolphe Brongniart and Leandre. Mr. Coppin was second with a very indifferent stand. In the class for twenty-four the Rev. H. H. Dombrohn was first with a stand in which were some fine spikes, while others told of the straits to which he was driven to make up a stand of twenty-four on September 20th. They were Marchioness of Lothian, Meyerbeer, Mignon, Antiope, Zampa, Norma, Eugène Scribe, Etendard, Horace Vernet, Leda, Christophe Colomb, Venus, Panorama, Chloris, Murillo, Lydie, Adolphe Brongniart, Amaranth, Frametta, Leandre, and Psyche. Mr. Julius Sladden of Chipping Norton was second.

In the miscellaneous class some admirable stands of Roses were shown by Messrs. William Paul & Son, Mr. Cranston, Mr. Turner, and Mr. Corp. Amongst Mr. W. Paul's was a very promising seedling called Pride of Waltham, as shown something between Mdlle. Eugénie Verdier and Madame Marie Cointet, also Hero of Waltham. Mr. Turner had a beautiful collection of bouquet Dahlias consisting of Flora Macdonald, yellow; Startler, lilac-tipped; Little Arthur, orange; White Aster, white; Baby Waite, lilac; Louis Rodani, deep lilac; Crimson Beauty, dark crimson; Vesta, white; Amelie Barbier, white-tipped; and Little Dear, white-tipped. He had also some baskets of charming plants of Tree or Perpetual-flowering Carnations, comprising Sir Garnet Wolseley, Vestal, Balacava, Coronation, Lady of Avenel, white; Osman Pasha, red; Guelder Rose, white; Amateur, light crimson; Mazepa, flaked; and Rose Perfection. Extra prizes were awarded to the several exhibitors.

First-class certificates were awarded to Mr. C. Turner for seedling Dahlias Charles Lidgard and Lady Golithly, and for Potato Schoolmaster; to Messrs. Kelway & Sons, Langport, Somerset, for seedling Gladioli Marcianus, John Laing, Venulus,

and Richard Dean; to the executors of the late Mr. Harrison, Catterick Bridge, Yorkshire, for seedling Dahlia Rosy Circle; to Mr. John Keynes, Salisbury, for seedling Dahlias Robert Burns, Dictator, Emulator, and Marion; to Mr. J. Betteridge, Aster Nursery, Chipping Norton, for seedling Quilled Aster Novelty; and to Messrs. Rawlings Brothers, Old Church, Romford, Essex, for seedling Dahlia James Willing.

It will thus be seen that for all lovers of florists' flowers there was something worth looking at, and hopes were expressed by many that this might be but the commencement of a revival of good autumn shows at the Crystal Palace. The authorities have been sounded on the subject, and I am hopeful that something may be done.—D., *Deal*.

VEGETABLES.

An extensive and excellent display was provided, the finest that has been seen since Messrs. Carter's fifty-guinea cup was won by Mr. Gilbert at South Kensington. Only two classes were provided, but the competition was good and the produce was of superior quality. In the class for the "best collection of vegetables, to be shown in shallow boxes 3 feet wide," there were eleven competitors, and as the boxes were neither restricted as to length nor limited as to number, some of the collections were of great extent and had quite an imposing appearance.

The awarding of the prizes occupied a considerable time, but eventually the honours fell, first to Mr. Pragnell, Sherborne Castle, for an extensive collection of remarkable quality; second to Mr. Chaff, gardener to C. H. Goschen, Esq., Ballards, Addington, for a collection consisting of fifty-four varieties; and third to Mr. Durant, 4, St. George's Terrace, Hurstpierpoint, for a small collection, but of first-rate quality. Every kind of vegetable grown in gardens was represented in the above collections, and nearly all in the first order of excellence.

In the cottagers' class for a collection of not less than six distinct kinds there were thirteen competitors, and much really superior produce was staged. Mr. Durant won the first place with a collection of splendid quality; Mr. W. Patchill, Bandon Hill, Beddington, Croydon, had the second; and Mr. Brookes, Bandon Hill, the third prizes. Considering the small amount of the prizes and the great merit of the collections, the authorities would not have erred had they awarded an extra prize or two in this class.

Mr. Walker, nurseryman, Thame, Oxon, was worthily awarded an extra prize for a collection of his "exhibition" Onion. None of the bulbs were less than 14 inches in circumference, and they were bright in colour, firm, and of handsome shape.

Good as other sections of the Exhibition were we do not hesitate saying that the vegetables were one of the finest features of the Show.

This was the first Show at the Palace held under the sole management of Mr. Thomson, who exerted himself to the utmost to make it a success, and succeeded.

NOVELTIES IN THE ROYAL GARDENS, KEW.

On the wall of the herbaceous ground we were much pleased with a fine example of *Clematis Davidiana*, not long introduced, and received here from Paris. It is a native of China, and similar in habit to *C. tubulosa*, from which, however, it is abundantly distinct. The flowers are produced in large clusters in the axil of every leaf to the extreme ends of the year's growth. The terminal clusters are many of them more than 3 inches in diameter, having about fifty expanded flowers with many buds concealed beneath. Their colour is porcelain blue, each flower resembling the pip of a Hyacinth. This species, unlike the majority, has no tendency to climb, the branches are stiff and erect, bearing broad, ample, dark green leaves.

Crinum Moorei has flowered in the cool division of the new range, and while being one of the finest of the genus, is also nearly if not quite hardy, and well suited for greenhouse cultivation. The flowers are of large size with broad segments, varying in colour from deep pink to nearly pure white. It is very desirable on account of its decorative value, and is very easily cultivated. It is supposed to have come from the interior of Natal, but we believe it may also be found further north. Several nearly allied forms are native of Africa.

Mr. Bull's beautiful *Eucharis candida* has flowered in the Begonia house. It is the plant to which the name truly belongs. That often usurping it is *Caliphuria subdentata*, inferior in more than one respect, in particular that it may not flower for years. *Eucharis candida* is from the United States of Columbia. It is similar in habit to *E. grandiflora*, but the flowers, though smaller, are much more elegant in form. The scape is about 2 feet high, bearing several flowers, the tube 2 inches long, perianth 2 inches across, with a funnel-shaped corona. It requires the cultivation of its well known ally, and several bulbs should be grown in a pot.

Gloriosa superba var. *grandiflora* is a splendid form flowering in the Stove. It is quite distinct from *G. superba* and of much larger size; the segments are clear yellow near the base, passing above into deep crimson. It is much superior in colour and also in the beautiful marginal undulations. *Chirita sinensis* has here been very attractive. It has a very short stem; the leaves are thick and fleshy, veined with white, and spreading in a rosette completely hide the pot. The flowers are pale lilac, and profusely produced on stems just above the foliage.

Among the Orchids *Angræcum arcuatum* has flowered in this collection for the first time. The flowers are white, sweetly scented, with sepals and petals recurving gracefully and produced several together on a short spike. *Vanda lamellata* is interesting in appearance and very free-blooming, but without the showiness of its better known relatives. *Epidendrum radiatum*, allied to *E. cochlearatum*, has a large shell-shaped lip with radiating purple lines. *E. ibaguense* is ornamental with lilac flowers. *E. scriptum* has peculiar insect-like blossoms with petals reduced in size to mere threads. *Masdevallia Davisii* and *M. Peristeria* represent the ornamental and curious of this genus. The former is bright yellow, in the form of *M. Lindenii* or *Harryana*, and the latter of brownish colour seated low down among the leaves. *Lælia Dayi* is extremely pretty growing in a basket; the lip forms a tube with rich purple mouth. *L. xanthina* is also in flower. Several specimens of *Cattleya crispata* in good varieties have just finished a fine display. *Dendrobium Johannis* is one of the curious species from Australia. It has long erect stems, bearing yellowish brown flowers with sepals and petals twisted much in the same way as *D. tortile*, but unfortunately without the fine colour of that species. *Miltonia candida* var. *grandiflora* has a beautiful white lip, well contrasted with orange and brown sepals and petals. *M. spectabilis* and *M. Regnellii* are also in bloom. *Compæretia coccinea* is pretty with flowers of Oncidium shape and colour, which the name indicates. The more ornamental Orchids, besides some already mentioned, include *Dendrobium Gibsonii*, *D. Bensonii* and *D. sanguineolentum*, *Stanhopea graveolens*, *Mesospinidium vulcanicum*, several *Oncidiums*—*O. Kramerii*, *Wentworthianum* and others, *Calanthe Masuca*, *Cypripedium superbiens* and *C. Sedeni*.

Rhodochiton volubile has flowered magnificently during the present season in the Temperate house, its slender stems hang down and form quite a curtain of flowers and foliage. *Campanula pyramidalis* and the variety *alba* are here very effective, growing with several stems from a pot. *Solanum venustum* is a graceful and slender climber flowering in the Palm house. The flowers are pale lavender in colour, and hang in large panicles. It is extremely rare, and though grown for some time in the Royal Gardens may be considered new. *Torenia Fournieri* continues to flower with great freedom in the Lily house, and has the advantage of shrubby growth so as not to require a single tie.

In the Stove are two very sweetly scented plants, *Tinnæa æthiopica* and *Coffæa travancorensis*. The flowers of the former are of the peculiar brown colour often associated with delicious odour, as in *Boronia megastigma*; the latter is no less attractive from its multitude of small white flowers than its delicious perfume, which somewhat resembles *Gardenia*. *Juanullosa parasitica* is considerably ornamental, having small Datura-like flowers with both orange calyx and corolla. The prettiest of the species of Balsams is perhaps *Impatiens Jerdoniae*, now profusely flowering in the Begonia house in a basket. It is scarcely 6 inches in height, and with pretty foliage bears an immense number of crimson and yellow flowers of peculiar form. The rare *Spigelia splendens* is just going out of bloom.

The tuberous-rooted Begonias are in great display, and their showy colours have recently been contrasted with the white flowers of *Campanula Vidalii*, producing a fine effect. *B. Pearcei* with bright yellow flowers is one of the most attractive, and with cool treatment is infinitely finer than when, as formerly, grown with the warm shrubby species. *Allium pulchellum* is very pretty on the rockwork. *Mecynopsis Wallichii* has long been in bloom and is just passing off. *Phygelius capensis* has recently been highly effective on the wall of the Orchid house, where it has surprisingly developed.

YELLOW ALPINE AURICULA.—The fine variety of this, to which Mr. Llewelyn refers as having been seen by him on the high Alps of Switzerland, is in all probability *P. auricula marginata*. The flowers of this quite answer the description given by Mr. Llewelyn, and no show Auricula that I am acquainted

with has such handsomely-powdered foliage at this season of the year. I obtained my plants from Messrs. Backhouse & Son, York.—RICHARD DEAN, *Ealing*.

ANEMONE JAPONICA ALBA.

AMONGST autumn flowers there are few which surpass this beautiful Anemone, and if grown in deep rich soil it will continue to produce a good succession of flowers for a long time. It is an herbaceous plant, throwing up its flower stems about the end of August, and is in full bloom and beauty by the middle of September. Two or three-year-old plants will produce a large quantity of flowers of pure white colour, averaging $1\frac{1}{2}$ inch in diameter, which are very useful for cutting for indoor decoration, especially at a time when white flowers of this size and lasting property are not very plentiful.

Fig. 49.—*Anemone japonica alba*.

It is readily increased by offsets, which spring up, as if by runners, near the base of the plant. If these are taken up with a few roots attached to each, and planted in nursery rows 6 inches apart any time this month, they will make flowering plants by next September, and the year following will be very good. Plants may also be increased by cuttings of the roots, placing them in pots in gentle heat. A mixed flower border, when it is backed up by evergreens, is a good situation for the plants, provided they are not overshadowed by large trees. Placing four or five good plants in a clump, or planted in a long row, they have a very telling effect. Good examples of this plant may be seen at the present time in Battersea Park near the south-western entrance, with shrubs in the background, and various flowering plants, such as Dahlias, Chrysanthemums, &c., with plenty of Heliotropes, scarlet and pink Pelargoniums, good patches of Mignonette, double Pyrethrums, and Carnations mixed with and in front of it, with good bands of blue Lobelia and Golden Chickweed (*Stellaria graminea aurea*) at the front of the border, and the effect is very fine. This *Anemone* is one of the most effective and conspicuous flowering

plants for autumn decoration. *Anemone japonica* with its pink flowers is a good companion plant to the above. It is of the same habit and height—2 feet. Mr. Ware, Tottenham, considers *Anemone japonica alba* one of the finest herbaceous plants in his large collection. It is also admirably suited for cultivation in pots for the decoration of the conservatory during the autumn months, where few plants have a finer effect.—A. HARDING.

CARDIFF CASTLE,

THE SEAT OF THE MARQUIS OF BUTE.

THE name is derived from the British *Caer*, a castle, and *daf*, the river Daf—literally, "The Castle of the Daf." It was built by Morgan Hen as far back as early in the tenth century, but was modernised by subsequent owners, especially by the Bute family, its present possessors.

Morgan is said to have begun building the town of Cardiff on the ruins of an old town built by Didi Gower, a Roman conqueror, and destroyed by the Saxons. Many alterations and improvements have taken place since the time we speak of, and the present Marquis is persevering with the restoration of the most decayed parts, but for all this much of its ancient grandeur is still preserved. Within the Castle enclosure stands the ruins of a keep. The Rev. Thomas Rees, who wrote "The Beauties of Glamorgan," after depreciating the modernising of some parts of the Castle, is delighted with the ancient ditch which surrounded the keep being filled up and made into a green lawn. Along with the many improvements in the grounds of late years this ditch has again been dug out to the depth of 10 or 12 feet and about double that width, which carries the imagination back to the grandest era of feudal days. Close to the gate by which the Court is entered there are the ruins of what is called the "Black Tower." Tradition assigns this as the prison of Robert Curthose, Duke of Normandy, son of William the Conqueror, who died here in the year 1133, after being imprisoned for thirty-six years.

Few places surpass Cardiff Castle in historic interest of the past, and very few will exceed it in gardening renown of the future. No lord ever entered the Castle who did more or was inclined to do more than the present noble proprietor, and it would be difficult to find one better able to carry out improvements than Mr. Pettigrew; but these few notes must not be taken as giving an account anything like equal to what will be afforded in a few years hence. This particularly applies to the pleasure grounds, and my remarks on these for the present will be brief.

The grounds are extensive; many trees have been planted in them lately, and groups and long borders of various kinds of choice shrubs formed, lawns laid down, and narrow and broad walks made. A stone-crushing machine is employed to prepare the metal for these walks, and everything so far as is completed is kept in good order. This applies to the ground close to the Castle. The kitchen gardens and another large piece of pleasure ground is separated from this by a canal and a turnpike road. Crossing this road from the Castle we enter by a door, close to which stands Mr. Pettigrew's house, and a little to the right from this lies one of the kitchen gardens and the principal ranges of glass.

The houses are not arranged in long rows as in some places, but some here and some there; all are, however, convenient for working and heating. The first two houses we enter are vineries 40 feet long each and 16 feet wide. Gros Colman planted three years ago is doing remarkably well here. It is common to say the berries of this variety are as large as Green Gage Plums; but here it is not too much to say they are as large as Kirk's Plum, and surpass in this respect the best I have seen. Some time ago there was a good deal said in the Journal about this Grape; there need be no dispute about the size and fine appearance of its berries, and when thoroughly ripened it will bear comparison with many others. One Vine of Madresfield Court Black Muscat in this house was bearing exceedingly fine bunches. Black Hamburgs were also a most creditable lot. The second division is wholly filled with Black Hamburgs. One Vine is being extended, and in a year or two will fill all this half, Mr. Pettigrew approving of the extension system of Vine-growing. The next house is a large greenhouse, well filled with all kinds of plants belonging to this department. Further along there is a Peach house 60 feet by 14. This house was erected by Messrs. Boyd of Paisley a few years ago. All the rafters and principal bearings are iron; Mr. Pettigrew is delighted with it. It is a lean-to like those

previously described, and the trees are planted along the front. It is only two years since they were planted, and the wood made both this and last year is splendid. The principal sorts here are Barrington, Noblesse, Royal George, and Bellegarde. These ranges are all facing the south.

There are two span-roofed houses with their ends facing north and south. Each is 60 feet long and 30 feet wide. Both are divided in the centre. One division is plant-stove and Melon house combined; plants are grown in the centre bed and on one of the side shelves. There is a narrow bed on the opposite side to this, and here Melons are grown in summer. The Melons here are treated differently to what they generally are. They are watered constantly at the root from the time they are planted until all the fruit is cut. That this is a good plan the plants and fruit bore strong indications. At the time of our visit the fruit was all ripe; many of them had

been cut that morning. The leaves and stems were spotless green and vigorous; and as to the flavour of the fruit, your report of the Cardiff Show states that Mr. Pettigrew was first for the finest-flavoured Melon, and this same fruit was cut from the plants in the damp soil. Mr. Pettigrew has a green-fleshed seedling of his own raising, named Cardiff Castle, which he grows extensively for its large size and superior flavour.

The next division of this house is Pine stove and Cucumber house combined. Pines are grown in the centre bed and Cucumbers at the sides. Some excellent Queens were swelling here, and robust young Smooth Cayennes gave promise of bearing heavy fruit. Winter Cucumbers were newly planted. Telegraph is the favourite here. The next house, the same size as this and in two divisions, is wholly devoted to Grapes. All the Vines are young here, many of them not in full bear-

Fig. 50.—CARDIFF CASTLE.

ing yet. Their health and strength is all that need be desired, and the fruit they are bearing this year is fine in every respect. Black Hamburgh and Black Alicante are the leading sorts in one division, Foster's Seedling and Muscat of Alexandria in the other. One side is wholly planted with Foster's. Mr. Pettigrew speaks and thinks highly of this Grape, and certainly he manages it well. Other pits and frames are devoted to young Pines, Melons, Cucumbers, &c.

Bottom heat is, as a rule, considered absolutely necessary to mature both Melons and Cucumbers, but Melons especially. In a pit here, with a bed in the centre and a row of hot-water pipes around the outside of it, there are both Melons and Cucumbers grown without bottom heat. There are no means of heating the bottom, and no fermenting material of any kind is put in—nothing but the soil, and that is not renewed every year. Last year Melons and Cucumbers were grown in the same place; the soil in which they were was never cleared out. Young plants were again planted in it this season, and the produce, both in point of quantity and quality, was as fine as it possibly could be in the best heated structure. The Melons are watered here until they are ripe, the same as in the house, and yet, although there is no bottom heat to dry up the soil quickly, they never wither up or die off just before

the fruit is ripe, as is often the case. But be it understood Mr. Pettigrew does not hold this as the very best way of growing Melons and Cucumbers.

Passing into the kitchen garden, three acres in extent, the eye is most attracted with the gay flower borders, but these soon lose interest in admiring the fine crops of vegetables. Many of the fruit trees here are young, and all bearing good crops. Outside the walls there are sheds and other such necessities. In the soil yard there is a large heap of decayed vegetables, leaves, grass, and other refuse. Vegetable Marrows are grown on this. At the time they are planted bits of Mushroom spawn are dibbled in all over the heap. These soon move, no doubt with the slight heat that must come from such a compost, and now Mushrooms are coming up thick under the shade of the Vegetable Marrow leaves.

About five minutes' walk across a field from this garden there is another new kitchen garden five acres in extent. This garden is in the corner of a picturesque field, where a high brick wall would not have looked well from the Castle or corresponded with other surroundings. There is, therefore, no wall round this garden, but it is surrounded with a high ornamental iron fence, which makes it quite in character with the park. It might be thought this would be an exposed garden,

having no wall for shelter, but everything appears to do well in it, and the crop of Apples and other fruits here is first-rate, which, unfortunately, is more than can be said of every garden this season. All the vegetables here show the excellency of the soil and management. "Winter stuff" of various kind form the chief crops, and the demand must be great indeed that will exceed such a supply.

As yet there is hardly any flower garden at Cardiff Castle, but this will be in proportion to the rest in a few years. A few beds are laid down on grass not far from Mr. Pettigrew's house. The *Tory Viola*, a splendid purple, raised by Messrs. Dicksons & Co. a few years ago, is very effective here. *Dumfries House Seedling Tropæolum*, raised by Mr. Pettigrew when gardener at a place of this name belonging to the Marquis of Bute in Ayrshire, is grown in quantity against some of the walls. It is a quick climber, and becomes a perfect sheet of orange-scarlet flowers.

There is only one thing to be regretted about Cardiff Castle and the gardens, and that is their closeness to the town of Cardiff, which deprives the place of that seclusion so desirable about such a noble seat. A stone might be thrown out of the Castle windows on to some of the streets, and the kitchen garden containing the glass houses is so close to the town houses that many of the windows overlook the garden.—VISITOR.

ATTAR OF ROSES.

OUR Naval Correspondent, who has been stationed with the Turkish army engaged under Suleiman Pasha in attacking the Russians in the Shipka Pass, takes the opportunity of a pause in the conflict to discuss the very different subject of Rose water. He writes from Kezanlik :—

"Perhaps there are few more fertile valleys in Europe than this once flourishing valley of the Tundja, which lies between the greater and lesser ranges of the Balkans, and stretches east and west far upwards of 130 miles. Although the nature of the soil naturally varies very considerably in such an extensive tract of country, still there is no one part that can be called bad or unprofitable, and, according to the locality, be it sandy slope with a southern exposure, as is the case on the north side of the valley, or alluvial lands in the lower parts, which in winter are converted into swamp by the swollen mountain streams, so whatever toil or labour the husbandman bestows he is repaid tenfold. To climb some of the lower ranges on the north side, which generally rise rather abruptly in rocky terraces immediately behind the villages, and look down on the varied colours of different cultivations, is a great treat for those to whom diversity in landscape has a charm. On the highest slopes grow the hardy Vines with their brilliant green leaves festooning themselves from one short pole to another, or trailing over the ground in the more stony places; as they do on the Lebanon. Next come the duller patches of Tobacco, at this season bearing the rose-coloured flower which spreads a flush over the whole field. Intermingled with these fields are the fields of Roses, the glory of the valley of the Tundja, growing in even rows, forming long lines like hedges, 4 or 5 feet high. Below these again are Wheat and Barley, with strips of pasture-land, dark groves of Elm trees, red-roofed villages, and white minarets.

"As is generally known, this district is the most fertile in the Turkish empire for the production of attar of Roses; and, as little is known of this curious and interesting process, a few words as to how the Roses are grown and how the essence is extracted may be permitted. This district, which is called the district of Kezanlik, produces annually more of the essence than all the other Rose-growing districts of Turkey put together. The whole quantity produced in Turkey may be roughly estimated at 3600 lbs. annually, of which 1800 lbs. are manufactured in this district, and the rest in seven other districts, all alike in the Sandjak, or Province, of Philippopolis.

"The soil best suited for the cultivation of Roses is what we find in such large tracts of land in this neighbourhood—namely, sandy slopes with a southern exposure, and the method of planting and rearing is as follows: In spring and autumn parallel trenches a few inches deep are dug in the soil selected about 1½ yard apart, and in these trenches are placed short branches taken from an old Rose tree. These must not be cut off the old plant, but torn off, so as to carry with them part of the peel or bark of the plant. They are placed in the trench so as to form a continuous line, and the earth with some manure is then filled in. In about six months small plants begin to show above the ground, but bear no Roses until the second year, and these are of no great value. The third year's crop is fit for the production of the essence, and by the fifth year the plant is at its best. It remains in this condition for several years, but after about fourteen or fifteen years the quality of the Roses has so deteriorated and the bushes grown so thick that replanting is necessary. By this time they may be 6 feet high. The Rose tree is a very

delicate plant and requires constant care. The value of the crop varies with the attention that is paid to them, the care in turning the earth, which has to be done three or four times a year, and the quality of the manure used. The frosts of winter do not affect the plants if they are continuous, but any sudden changes, especially towards spring, are most fatal. Hoar frost and fog when the first buds are appearing are also much dreaded. About the way of trimming the plants I could gather no information, but from their appearance it would seem that very little is done in this direction except cutting away dead wood. Budding appears quite unknown to them, nor would there be much use for this delicate art. There are few industries requiring more practical knowledge than the production of attar of Roses. When we take into consideration the immense amount of labour and land that is required to produce a very small bottle of this precious liquid, it will not surprise one to see how few people engage in the cultivation of the Rose. As April draws to an end the cultivator begins carefully studying his field, almost counting the buds, and scrutinising the heavens for any change in the weather which may necessitate his beginning his *récolte* earlier. A sudden burst of warm weather may bring his buds forward so rapidly in a day or two that he stands in danger of losing his whole crop because he cannot gather it all in; or a hoar frost, though not killing the buds, may take all the scent out of them and make his crop comparatively valueless. As the crop of flowers advances towards harvest time the cultivator has to make a kind of rough estimate of the quantity of buds and flowers that he must gather each day. This is limited by the amount of labour he can command to pick the young fresh-blown Roses before sunrise and by the quantity he can distil at one time, for the sun soon dispels the scent, and the flowers must go immediately into the still. Thus supposing he sees or judges that it will take ten days for the whole crop to come to perfection, he must in the first morning gather a tenth of his crop and proceed to distil that quantity, and this will explain why a sudden burst of heat forcing on the whole crop is so disadvantageous. It also appears that any great heat during the time of distillation causes the quality of the essence to deteriorate. The distillation is carried on in the most primitive manner, and yet seems to answer the purpose as effectually as would any more complicated or scientific method. The still itself in form resembles a huge copper bottle, with a neck consisting of a smaller chamber. The height of this still is about 5 feet. From the top a pipe passes into a receiver, through which the distilled water passes. Into this still is placed a quantity of Roses with ten times as much water, and the distillation is carried on until the amount of liquid in the receiver equals in weight the amount of Roses in the still. The Roses are then thrown out and a fresh quantity put in, and the process is repeated until all the water is evaporated, when a fresh operation begins. The liquid thus obtained is Rose water, which is again subjected to distillation, when the real essence is produced in the form of a pale yellow oil. The quantity of essence that a given number of Roses will produce is very uncertain, but a rough average may be taken that to produce 1 lb. weight of the essence it requires the astonishing weight of 28 cwt.

"From this may be gathered some idea of the enormous amount of land occupied and labour bestowed on the cultivation of Roses in this district alone, which annually produces upwards of 1800 lbs. to 2000 lbs. weight of the essence. There are no large farmers of Roses. The rural population have the manufacture entirely in their own hands, and every man that has a small field of Roses has also his distilling apparatus. Very often among the poorer Bulgarians this constitutes their entire capital, with a small field of Maize, a few Plum trees, and a few Vines.

"In this way the inhabitants of the valley of the Tundja passed their lives, in that degree of ease which Turkish extortion and every kind of bad government would permit them, and in comparison with the poor Irish or the country clod in England they were well off and happy.

"But a misfortune of a terrible kind has overtaken Bulgarian and Turk alike, and in the whole length and breadth of that exquisite valley there is hardly a house standing or a crop that has not been destroyed. I am sitting under the verandah of one of the two remaining houses of a large village called Chourloo, about two miles from the entrance of the Shipka Pass. In this village upwards of eighty Turkish women and children were massacred by Bulgarians, and my host, with Turkish *sang froid*, is sitting smoking cross-legged under a pergola of Vines, about 10 feet from a small heap of earth where his wife lies buried. She was massacred a day or two before the army of Suleiman arrived. Behind the house, thrown on to the manure heap, and picked as clean as bones can be by crows and dogs, lies the skeleton of his uncle. Ten minutes' ride carries you to a Bulgarian village, where exactly the same sights are to be seen, though in the proportion of about ten to one of victims. The most impartial cannot but admit that the Bulgarians have suffered far more than the Mahomedan population.

"In pondering over the future of this country, one of the

most difficult matters for solution is the re-distribution of property. To find the rightful owner in cases where a whole family have been destroyed and settle such never-ending conflict of claims will find employment for generations of Turkish lawyers, if the fate of the war leaves it to them to decide; while the additional complication may arise of confiscation for the Bulgarians who have joined the Russians and have become *de facto* rebels, or for the Turks who may be mulcted in their land for indemnities to Bulgarians whose property they have destroyed. Whichever side gains the day, it will open a fruitful field for roguery and rapacity, and the unhappy dwellers in these lands will by no means see their troubles terminate with the war."—(Times.)

NOTES AND GLEANINGS.

THE INTERNATIONAL POTATO EXHIBITION will be held in the Royal Aquarium on Wednesday, Thursday, and Friday next. Considering the peculiarities of the season, the Exhibition should, and we do not doubt will, prove especially useful as illustrative of the relative value of varieties, and methods of cultivation. It is certain that good cultivation is in some degree preventive of disease, for in the worst Potato years the Potato fanciers lift good sound crops.

— THE finest GOLDEN CHAMPION GRAPES we have yet seen have been grown this year by Mr. Mowbray, gardener to the Earl of Leven and Melville at Fulmer, Bucks. A Vine is planted at the back of the vinery and trained a few feet down the roof. It produced splendid fruit last year, and this year it has produced bunches as regular as any Black Hamburgs, while some of the berries measured fully $4\frac{1}{2}$ inches in circumference. They were perfectly free from spot, were of a clear amber colour, and of excellent flavour. They would have gladdened the eyes of Mr. Thomson as they did those of Mr. Solomon, the eminent fruiterer of Covent Garden, who pronounced them superior even to the Clovenfords produce. A small bunch from this Vine was awarded an extra prize at the Crystal Palace Show.

— MR. DOBREE, The Priory, Wellington, Somerset, had the first prize in the amateurs' class for twenty-four DAHLIAS at the Alexandra Show. The other prize-winners in that class were named in our report. In the class for twelve Fancy Dahlias the prizes were awarded to Messrs. Keynes, Dobree, Glascock, Rawlings Brothers, and Saltmarsh & Sons.

— IN last week's Journal a correspondent asks about BEECH-NUTS. We have here some fine specimens of Beeches; they are so loaded with nuts that they have assumed quite a pendant habit, which adds quite a charm to their noble appearance. I never saw them so loaded before; the squirrels are having a jolly time of it among them, but that does not prevent the rascals visiting our choice Filbert plantations.—NORTH YORK.

— ON the 18th inst. the Master (Mr. Samuel Williams), the Wardens (Mr. Henry Bollen and Mr. Alderman Knight), and the Court of the Fruiterers' Company, waited by appointment upon the Lord Mayor in the saloon of the Mansion House, and presented him with an excellent assortment of the choicest FRUITS of the season, including Grapes, Peaches, Apples, Pears, Melons, and Green Gages. Formerly the gift consisted of twelve bushels of Apples, which, neatly packed in clean baskets and covered with linen napkins, were brought from Farringdon Market by porters, escorted by the beadle of the Company, to the Mansion House. On its arrival in former days the Lady Mayoress used to direct the housekeeper to take charge of the fruit and put a bottle of wine in each basket for the use of the carriers, who were "regaled" with a dinner. At the ceremony on the 18th the Lord Mayor was accompanied by Lord Elcho, M.P., Mr. Scott Russell, the Rev. R. J. Simpson, Sir John Bennett, and other gentlemen who had been with him on public business. The Master of the Company in appropriate terms offered the fruit for the Lord Mayor's acceptance, and his lordship suitably acknowledged the gift, and, following the custom, invited the Company to dine with him at the Mansion House later in the year. James I. in the year 1605 instituted the Fruiterers' Company, and granted them arms—these are the Tree of Knowledge entwined by a serpent, and Adam and Eve standing one on each side. The Company's motto is "*Deus dat incrementum*," God gives the increase.

— THE BERKHAMPTSTEAD COTTAGE GARDEN SOCIETY held their Annual Exhibition of flowers, fruit, and vegetables at Berkhamptstead on the 17th inst., under the presidency of

Earl Brownlow. During the afternoon Mr. John Hunter delivered a lecture on bee-culture, accompanied by practical demonstrations with living bees, which much interested the large company assembled.

NOTES ON VILLA AND SUBURBAN GARDENING.

THE changing of colour of Virginian Creepers and various other trees and shrubs which precedes the fall of the leaf only tells too plainly that autumn is near at hand. We must prepare ourselves to meet it. Greenhouses and other structures that have been emptied of their occupants for the purpose of hardening-off or for enabling such houses to have a complete overhaul in the way of repairing, painting, and whitewashing, ought now to be completed, and the plants be returned at once to their various homes.

Cuttings of Geraniums and other plants likely to suffer by frost, and which were recommended some time since to be placed out of doors, will require to be watched. In the case of sudden frost any temporary covering will protect them, but potting them singly in small 60's and housing them must be proceeded with as rapidly as possible. It frequently happens that we have just sufficient frost on one or more nights to turn the more tender plants black and useless, and afterwards a short period of warm and fine weather. We have already heard of frost occurring in several localities, but where French Beans and Vegetable Marrows have not suffered a timely covering over these on unfavourable nights will prolong their supply.

Any Alternantheras or other bedding plants required as stock plants to furnish cuttings in the spring should be taken up, potted, and placed in a warm house at once; but every effort should be made to prolong the attractive beauty of the flower garden for a little while yet by occasionally running the mowing machine over the lawns, picking off decayed flower trusses, clipping the edges of the beds, and sweeping up the wormcasts, which are becoming troublesome.

Note any errors in the arrangement of your flower beds that you wish to remedy for another season before it is too late.

Alterations and making of new borders, beds, and plantations can be now commenced; the weather of late has been very favourable to the lifting and transplanting of all shrubs and for the relaying of turf. It too frequently happens that in laying out villa gardens a great variety of shrubs are planted. Sometimes good specimen plants are planted amongst Laurels and other commoner shrubs; this is a mistake, and nearly always when a garden is first laid out the shrubberies are planted thickly so as to give effect at once. Wherever this is done the shrubs will require timely thinning, otherwise they will grow into each other and become a tangled mass. A judicious thinning becomes absolutely necessary, and if there is room in other parts of the lawn or grounds we advise preparing other borders to receive them, and if this is begun at once the transplanted shrubs will have a chance of making fresh roots before the extreme cold weather is with us.

Rhododendrons remove well at any time; their small fibrous roots are so numerous that a good workman finds no difficulty in lifting them with sufficient balls to ensure their safe removal. Very many of the Conifers have strong coarse roots, particularly the Wellingtonias and Cupressuses, it would therefore be almost certain death to remove any of these that had made rapid growth and become coarse at the roots; it would be far better to root-prune them first for a season and lift them the next. In all our best nurseries from whence specimen shrubs are annually supplied the whole of them are annually lifted to prevent a coarse root-action, and consequently to promote the emission of fibrous roots around the stem, and large shrubs are then lifted and sent safely almost any distance. Yews, Laurels, and many other shrubs will bear lifting better; they may also be out-in with a knife to make space to admit light and air to choice contiguous specimens. In preparing for fresh plantations trench the ground deeply, for shrubs will make much more rapid progress in well-prepared ground than in ground which has had little or no preparation; and it is surprising how well most shrubs will grow in poor stony subsoil if it has once been deeply broken up and become incorporated with the top soil. We have had great experience with poor, light, gravelly soils, and by adopting the above method and keeping down weeds during the summer shrubs of all kinds have grown exceedingly well. Another very important point in removing shrubs is to plant them again as speedily as possible, for the shorter time their roots are exposed to the air the greater is the chance of their taking more speedily to their new quarters.

In the kitchen-garden department continue to plant-out for the spring supply Cabbage plants as they become strong enough. Thin the autumn-sown Onions if there is a likelihood of their being too thick. The thinnings may be transplanted or used young. Continue planting-out fresh breadths of Endive and Lettuce, and tie-up both kinds, if required, to blanch; also earth-up Celery, choosing dry days for this work. The first planted rows will now be ready to receive the final earthing-up.

Thin-out Turnips where they are too thick, they will form the quicker and withstand the winter better, and ply the hoe amongst the myriads of small weeds which have sprung-up during the past damp and dull weather. Remove the weeds to the rubbish heap, together with any decayed vegetation, as the sun after this will not have much power in destroying them, and the heavy dews at night will cause them to take root again.

Expose Tomatoes to the light as much as possible, and any changing colour should be cut and removed under glass, where they will soon ripen.

Chrysanthemums require daily attention to disbudding, training, and watering; and Fuchsias which have ceased blooming should be placed out of doors for a few days to finally ripen-off prior to housing them for the winter.—J. W. MOORMAN.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

KITCHEN GARDEN.

The weather with us has during the last two or three weeks been extremely favourable for out-of-doors operations; very little rain has fallen during that time, and the soil is dry. A good soaking of manure water would very much benefit green crops intended for winter use. Drainage from the farmyard is well adapted for this purpose, but in many cases such useful fertilising material is allowed to run to waste. Sewage water is also very valuable for watering; the late Mr. R. Fish used quantities of it both to water the roots and also over the leaves. He stated that it drove away red spider and green fly, and also prevented insects from settling on the leaves to lay their eggs. Our Brussels Sprouts are not growing so freely this year as they have usually done, and are therefore later than usual. It is well to make two sowings of Sprouts, one in March and the other a month later. The earliest sowing should now be well advanced, but the sprouts do not form well unless the heart is taken out of the plant. We shall be glad of the Coleworts, which will be in use from now until Christmas; after which Savoys will be the best, to be succeeded by Sprouting Broccoli. It has been excellent weather for earthing-up Celery; this is an operation that must be done in a careful manner. It is a good plan to tie the leaves together with a strip of matting, and after breaking down the edge of the trench with a fork or spade hold the Celery plant with the left hand, and with the right place the finely-broken soil round the plant. In this way the finer particles will not choke the centre, and thus prevent the development of the plants. Onion, Cauliflower, and Lettuce seeds sown two weeks ago have germinated very freely. The Lettuce and Cauliflower plants are frequently at this season attacked by slugs, and many of them are destroyed; we shall dust the rows over at night with fine-ground lime, which will prevent the slugs doing much mischief. We have been looking over the Potatoes and find that the disease has destroyed a considerable portion of them. This has been a very trying season for the Potato plant: first the cold east winds in the spring, with frost at night after the leaves were formed, stopped the growth, and in many instances a second growth had to be made; this told very seriously against the crop. Now the disease is likely in many instances to destroy half or more of the crop that has arrived at maturity. Except storing Onions for winter and early spring use, and digging vacant ground, but little other work has been done in this department. Some of the ground now prepared by digging and manuring will be planted presently with Cabbage plants for use in May, June, and even into July. Early York or Atkins's Matchless, planted much closer than usual and in a warm position, will be found very useful for cutting from before the general crop comes in. Those who grow Tomatoes on the walls will do well to take heed that frost may come suddenly, and it would be well to prepare for this by cutting the fruit and placing it on shelves in the vinery or some other structure where it may ripen. In our uncertain climate it is better to grow Tomatoes under glass, but those who have not this convenience will find they do best on a wall facing south or west. Only in very early districts and favourable circumstances will they do well planted in open borders.

VINERIES.

We alluded two weeks ago to the necessity for great care in heating and ventilating houses where Grapes are hanging for use during winter and the early spring months, and also to see that the decaying berries are removed at once to prevent further injury to those which are sound. Another matter connected with forcing Grapes is too often overlooked, and that is the maturation of the wood after the fruit has all been gathered. It does not always follow that because the wood is strong and brown that it is also well ripened; in fact the contrary is often the case, especially if the leaves have been prematurely destroyed with red spider or scorching. The leaves ought to remain in a healthy condition for some time after the fruit has been gathered, and to secure this they must be free from insect pests, and the roots must also be in a healthy growing condition. It is a fact that at this time the roots are much more active than they are in

the earlier stages of the Vine's growth. We have also repeatedly urged the importance of having the borders sufficiently moist to their full extent; and further, it may even be necessary to keep the house closer for a little longer, and also to maintain a higher temperature by artificial means.

Vines in pots intended to be placed in the forcing house early in November must now be cut back, and either be placed out of doors where the pots can be protected from heavy rains, or they may be placed in the house intended for them if it is ready for their reception, and no more water should be given to the roots than is sufficient to keep them from being injured. When starting them a little bottom heat is an advantage, but this must bear some proportion to the temperature of the house. It is not natural and there is nothing gained by plunging the pots in a bottom heat of say 90° and a temperature for the tops of say 45° or 50°. If the bottom heat exceeds 70° we would not plunge the pots very deeply into it. Vines in pots require very much attention as regards watering; if they suffer in this respect the leaves will soon tell the tale of their sufferings.

Strawberry Plants in Pots.—These are now maturing their growth for next season. The crowns are already very full, and give promise of good results next year. All the attention they require at present is to see that the roots do not suffer by want of water, and to remove all runners as fast as they are formed. We are also careful to see that each plant is fully exposed to the action of the sun's rays. If the plants are crowded together it is not possible that they can come to perfect development.

PLANT STOVE AND ORCHID HOUSES.

We have been very busy during the last week or two in thoroughly cleansing the plants and also the wood and glass-work of the houses. During the summer months we are not careful to thoroughly clean and wash the glass very frequently; but now with the shortening days and cold dull weather every ray of sunshine obscured will tell against the health of the plants. We do not expect to do any more potting until the days are about as long in spring as they are now, and our work will now be cleaning plants, and tying-out and preparing specimens for next season. Choice climbing plants, such as *Stephanotis floribunda*, *Dipladenias*, *Clerodendron Balfourii*, &c., are now having their growths trained to strings; these are fastened to the trellis, and the shoots are trained singly along them in the direction of the glass, and also under the glass within about 6 inches of it. It is necessary that the glass should be quite clean over all such plants, and when the wood is ripening not less than 65° of heat should be maintained at night, with a proportionate rise by day. Very important also is it to thin-out the young growths; we not unfrequently see large specimen plants making vigorous growth at this season, and the growths, four or five together, twining firmly round a stout wire; it is not possible to obtain good results if plants are allowed to grow so. Such management, or want of management, reminds one of Allan Ramsey's lines, where he says—

"I love the garden, wild and wide,
Where Oaks have Plum trees by their side;
Where Woodbines and the twisting Vine
Clip round the Pear tree and the Pine;
Where sweet Jonquils and Gowan blow,
And Roses 'midst rank Clover grow."

All very well in its place, and others besides the poet could appreciate it; but this style is quite out of place in well-managed hothouses. The importance of carefully training the young growths of climbing stove plants has been repeatedly urged in these columns, and when they twine round permanent wires it is best to untwine them and arrange the growths out regularly on the trelliswork. The good old *Allamanda Schottii* is a magnificent plant to train to the rafters of large houses, and at the time it is in flower it is best to allow the young growths with the flowers to hang loosely about. Although it may be classed as a climbing plant, the growths do not twine round the wires to which it may be trained. The plants are now profusely in flower. Except on one occasion that the leaves were attacked with red spider where they could not be readily syringed, we have never had any insect pests fasten on it. For smaller houses the species *A. grandiflora* is extremely beautiful; it flowers profusely, and the blooms are quite distinct from any other sort. We have cut-back the young growths of some of the *Dipladenias*, and as the plants are nearly denuded of leaves it gives us a golden opportunity to wash the plants thoroughly and to free them from bug.

Orchids under cultivation must be said to have their season of rest during the months of November, December, January, and February; but it would be a great mistake to dry the plants off indiscriminately, as some species are now in flower, others are throwing up their flower-spikes, and more starting into growth. Those that have completed their growth and are intended to flower during the spring and early summer months must be rested by withholding water, so that the growths may be consolidated. Many of the *Dendrobates* answer to this description, and no water should be applied as long as the growths remain plump; should they begin shrivelling apply water, but

not to the pseudo-bulbs. Cattleyas also enjoy a season of comparative rest if their growths are formed, but those having growths in the course of formation must have water sufficient to prevent any check. Phalenopsis also, although it is not well to allow them to become so dry as is required for Dendrobiums or Cattleyas, must not be gorged with water during the winter months, and it is necessary to be careful that none falls on the leaves. We do not have any water in the evaporating troughs after this time of the year, but it is necessary to sprinkle the paths and stages to maintain a certain degree of moisture.—J. DOUGLAS.

TRADE CATALOGUES RECEIVED.

James Veitch & Sons, Royal Exotic Nursery, King's Road, Chelsea.—*Catalogues of Fruit Trees, Dutch Bulbs, &c.*

James Carter & Co., High Holborn, London, W.O.—*Catalogue of Dutch Flower Roots.*

William Paul & Son, Waltham Cross, London, N.—*Catalogues of Roses and Bulbs.*

E. G. Henderson & Son, Pine-Apple Nursery, Maida Vale, London.—*Catalogue of Dutch Bulbs and other Flower Roots.*

William Barron & Sons, Elvaston Nurseries, Borrowash, Derby.—*Catalogue of Conifers, Fruit Trees, Roses, &c.*

Henry Merryweather, The Nurseries, Southwell, Notts.—*Catalogue of Roses.*

Wm. Clibran & Son, Oldfield Nursery, Altrincham.—*A Descriptive Catalogue of Dutch Flowering Bulbs, Roses, Conifera, Shrubs, Fruit Trees, also Spring Flowering and Herbaceous Plants, &c.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (M. J.).—"The Greenhouse, its Plants and Management," free by post if you enclose eleven postage stamps with your address. (M. B.).—"Our Kitchen Gardening for the Many," free by post from our office if you enclose six postage stamps with your address.

ROSES (Marlow).—It is impossible to name Roses from small specimens. They are too numerous and too nearly alike.

GRAPES (Ibid.).—The Vines probably require more moisture at the roots, and tepid liquid manure occasionally. The bunches of Grapes should be thinned more.

FRENCH MARIGOLDS (H. Cannell).—They are splendid. We never saw finer flowers, nor petals more regularly or brilliantly striped.

DOUBLE PELARGONIUMS (Q. L., Ireland).—We presume your variety is a seedling. It resembles Madame Emilio Baltet (Lemoine), which is the best of the double white varieties. The truss you have sent is of medium size, flowers double and well expanded, petals smooth and pure white. It is worthy of being submitted to the Floral Committee of the Royal Horticultural Society. It is a good variety, but whether it is distinct from the one named can only be ascertained by a comparison of plants in a flowering state.

OLEA EUROPEA, &c. (Willesden).—Neither the Olea nor the others are hardy.

PRIMULAS "FLOWERING PREMATURELY" (Amateur, Bristol).—We do not consider them premature at all. If the plants were not sufficiently strong to flower now, they would not be likely to make a fine display in the spring. Pinch-off the flowers, and as the plants are only in 4-inch pots repot them into 6-inch pots, draining thoroughly and employing a compost of turfy loam, very decayed and dried manure, or failing this, leaf soil and peat in equal parts with a liberal admixture of silver sand. Do not pot the plants deeply; they may be kept in an upright position by three small sticks an inch or two long inserted around each plant. Place them on a shelf in the greenhouse, and with good attention you will have fine plants in the spring.

WINTERING ALTERNANTHERAS (J. M.).—As you have not struck any cuttings, take up some old plants before they are injured by the frost. Pot them in good soil, and winter them in a cool stove—that is, a house having a minimum temperature of 50°. In the spring place them in brisk heat and they will yield an abundance of cuttings, which may be rooted and prepared for planting-out when the weather is favourable. They cannot be safely preserved in a cool vinery or greenhouse.

HARDY APPLE (Clericus).—You have been rightly informed that Cellini has withstood the inclement weather of last spring better than many other varieties. We have seen it in many gardens bearing excellent crops, while the majority of the trees surrounding it were barren. It is a very useful autumn Apple.

CONIFER FOR SMALL LAWN (J., Brixton).—As you require a specimen of "compact growth and conical habit yet less sombre than the Irish Yew," we advise you to plant Cupressus Lawsoniana erecta viridis. It is a cheerful and handsome Conifer for the small grass plot of a villa garden.

RIPENING THE WOOD OF VINES (J. T., Cambridge).—It is most important that the wood be well ripened, and fire heat is seldom more profitably employed than during the autumn. The advice that has been given to you to

remove the lights to "harden" the Vines is erroneous. It is heat, not cold, that matures the wood. As your Vines are still growing and the wood is soft, remove the laterals and apply fire heat—in fact, follow the advice which is given on another page by "A KITCHEN GARDENER," who ranks amongst the most competent Grape growers of the day.

GARDENIAS AFTER FLOWERING (Eve).—After flowering they are benefited by a short season of rest. This means keeping them only moderately moist at the roots, and in a lower temperature than that in which they have made their growth. Casti after flowering also require a season of rest. The plants should be freely exposed to the sun, and not any water applied to the roots.

SEEDLING BRIARS (A. Chapman).—We do not know where Briar seeds are sold, but they can be gathered in plenty in many places in the hedgerows. Sow in beds in the open air in early spring. The plants may be budded the second year close to the surface of the ground. The plants are very small the first year, but may be transplanted in the autumn, and make excellent stocks the next season. Mr. Prince of Oxford can supply seedling Briars at a cheap rate. We bought them last year at 1s. 6d. a hundred, or he can also supply plants worked on the seedling Briar.

TUBEROSES (M. L.).—These roots do best the first year, but if the roots are gradually dried off they will flower a second season. Keep the roots in a dry place during the season of rest in the pots in which they were grown. You should purchase the highest-priced roots if you desire the best results.

RENEWING VINE BORDER (Amateur).—If all the roots are outside we think it would be better not to lift the Vines until November. You might mix the compost for the border at once and place it under cover. If part of the roots had been inside you might have done the work at once. We would not use any manure except about a hundredweight of crushed bones to four cartloads of the turfy loam.

VINES ON WALL (G. A. Douglas).—The lights placed against the wall will very materially aid in ripening the Grapes, and your plan is good. We would leave a space of half an inch or so between the lights, as the air would be confined and cause the Grapes to mould. If you were to place the lights on early in the year it would be a still greater advantage.

HEATING SMALL HOUSE (A. Harrison).—The house might be heated from the kitchen boiler, but not as you propose. The tendency of hot water is to rise, and it would not circulate if the pipe falls from the boiler 6 inches in a short distance. Let the flow pipe be fixed near the top of the boiler and the return at the bottom; but there must be a slight rise of the flow to the point furthest from the boiler, and at that point an air pipe should be fixed. The two pipes may keep the frost out in severe weather, they will not do more.

VINES FOR LATE HOUSE (R. K.).—You might plant eight Vines at 2 feet 9 inches apart. The following sorts are the best for your purpose:—Three Black Hamburgh, two Lady Downe's, one Alicante, one Buckland Sweetwater, one Golden Queen.

LOPPING AUSTRIAN PINE (Dan).—We should do it now, though if the branches shade the Yew hedge much, we should for the sake of the hedge defer the lopping of the Austrian Pine branches until February or March.

GRAPES BURSTING—UNEVEN-SIZED BERRIES (Caught Napping).—The berries crack or burst from an overmoist atmosphere, with probably too much moisture at the roots. The remedy will be to discontinue watering the border, and to maintain a drier atmosphere: have gentle fires by day with efficient ventilation, leaving a little air on all night to prevent moisture being deposited upon the berries. The late summer has been so wet and unless that fire heat became with us a necessity in order to cause a circulation of air, a close moist atmosphere being fatal to the ripening and keeping of Grapes. The application of superphosphate at the rate you name is not only very extravagant but calculated to do more harm than good. We should remove the surface soil an inch or two deep, and replace with turfy loam to which has been added a sixth of charcoal. Uneven-sized berries are chiefly a result of strong wood imperfectly ripened, there being many uneven-sized berries in houses in which fire heat was not employed last autumn for the ripening of the fruit and wood.

WORMS—ANTS—IMPROVING THE TEXTURE OF HEAVY SOIL (J. L., Preston).—The worms would be best destroyed by an application of lime, which would much improve the texture of the soil. Gas lime is a powerful insecticide, requiring to be very carefully employed in gardens. The most that it is safe to use is a peck per rod, and it will not even at that rate be safe to employ it among plants. We should use lime in the fresh slacked state at the rate of six tons per acre, in February or March, though it may be used in October or November, and pointed-in with a fork. The ground would be best thrown-up roughly for the winter, and limed in March. This would destroy the worms. The ants may be driven away by sprinkling their haunts with guano. Ashes would tend to loosen the soil, rendering it more open and easy to work. Soot may be applied during the growth of the plants; it is a powerful fertiliser, and is good against predatory vermin.

DESTROYING ANTS (W. D. P.).—We fear that you will experience considerable difficulty in exterminating the ants from the pit of cocoa-nut fibre refuse in your greenhouse. Sprinkling with Scotch snuff in such a case is not likely to be efficacious. Pouring boiling water on the fibre might destroy many of the ants. We have not had experience with carbolic acid as an ant-destroyer. The plan you propose is worth trying. Try it and let us know the result. (W. C. B.).—We know of no mode of driving them away than sprinkling Scotch snuff or guano over their haunts.

NAMES OF FRUITS (Knutsford).—Devonshire Quarrenden. (Cannon).—Caraway Russet. (Hugh Strahan).—Summer Pearmain.

NAMES OF PLANTS (W. G. A.).—The numbers had slipped off the specimens; send others with numbers firmly attached. (M. E. D.).—Cassia corymbosa. It is a native of Buenos Ayres.

POULTRY, BEE, AND PIGEON CHRONICLE.

MICHAELMAS DAY.

As regards entries the first of the series of metropolitan shows in the number of its poultry entries can hardly be called a success, for it has just been beaten by Ipswich and Bath. It has hardly an average of nine throughout all the poultry classes, which for a London show is a small number, while Ipswich had

just an average of nine, and Bath was just over that number. In the case of the last two mentioned shows, however, we must state that there were other exhibitions of note going on in other places, while besides London there is this week no other meeting that we know of. We can gather from this that the rate of entrance fees is considered too high, and we heard many at Ipswich commenting on the excessive sum charged for entering in proportion to the prizes given at the London shows. We do not suppose any more unfortunate year could have been chosen to try to set four metropolitan shows afloat, for we are sure chickens so far of any merit have been scarce and backward, and are likely to be so for some weeks to come. It was a very late and cold spring, and the chickens did not grow or thrive. We have had opportunities of attending many of the best chicken shows which have been so far held, and also have seen the yards of many fanciers in the past few weeks, and we have found chickens scarce and late. We allow that the specimens so far which have come to the front have been good and quite worthy of their places, but the classes have mostly been small, and some birds would even have been better for a month or two more at home.

We believe there will be by the end of next month many more good birds about, and we daresay Oxford may not find itself with a much smaller number of entries, while at the Palace all will be ready who have any hopes of coming to the front; but we are assured by many breeders that their March and April chickens failed entirely, so that some will have to wait for the old birds' classes and be non-exhibitors of chickens at all this season, save in isolated cases where some chance bird has come forward better than its mates. At Stoke Park the other day we saw Black Cochins pullets, Light Brahmas, and Buff Cochins pullets which will do, probably, great things one of these days; but Mr. Wragg was as late as his friends, and his chickens mostly want more time. And so again with Mr. Cresswell: he has Silver Dorking pullets which we doubt at their age we ever saw excelled, and so with his White Dorking cockerels; but the Crystal Palace will see them in their prime, and no show before, though he may exhibit them at Oxford. The Little Ness birds, too, are all late—Cochins of all colours and the Polands; and Mr. Darby has as yet been quite unable to do the summer and early autumn chicken shows in his usual style. Mrs. Holmes has capital chickens coming on, and so has Mr. Norwood, and so with very many more. From all sides we hear the same stories. "So late," "All behind," "We must wait a bit."

Now how much better would it have been if one or two of the London shows had waited a while. Some time in December, after Birmingham, would have afforded them a good opportunity, and we still think there is a date then which could be taken by an enterprising Committee and made much of. Chickens there must be by then if there is ever to be a display, and after the Palace and Birmingham meetings exhibitors would in all probability go in for one more great show before settling down to the busy time of breeding. Bristol is dead, we fear. The proprietors of the Belle Vue Gardens at Manchester are no longer caterers for the poultry fancy, so we should like to see some party of fanciers in a large town seize upon the date we name, and make a great exhibition on the ashes of the dead. They will never have such another chance perhaps, for it may be years again before the birds are generally so late. We have heard rumours that the Agricultural Hall have in contemplation a monster exhibition of all sorts of fancy stock for that date, but we believe nothing is yet definitely settled, and, as far as we are concerned, we doubt if after the four in prospect it would be wise to start another show in the metropolis. If this Poultry Club which has now attained the management of so able a man as Mr. Cresswell ever intends to hold a show, the Committee can never lay hold of a better year to begin if they meet at the time we name. But though we have in no way abated our interest in this proposed body of fanciers amalgamating together, we do not see that a show is at all necessary to be held by them. In the full hopes of seeing large classes of good quality at the Alexandra, Oxford, and coming shows, we confidently look forward.—W.

WEYMOUTH POULTRY SHOW.

This Exhibition offered good money prizes in each class with a low entry fee, and consequently they got together some of the best chickens extant from the best yards. Mr. Dixon awarded the poultry prizes and gave satisfaction, and we only lament that from the clashing of other exhibitions this Committee did not obtain an even greater return for the prize money offered.

The Dorkings were admirable. The Coloured of Mr. Burnell and the Silvers of Mr. Boissier were most praiseworthy, and in these days when there is so much said against the honesty of egg vendors it may be interesting to many to learn that all the late winning Silvers of Mr. Boissier were hatched from purchased eggs. Mr. Beachey's Dorkings are thoroughly up to the mark, well grown and well shown. Cochins were of capital quality, the Buffs and Whites more especially so. In the latter

class the first pullet (Lang), was good, and also the first and second cockerels (Tindal and Woodgate). In the other Cochins class the Partridges excelled; Black cockerels are, we are afraid, few and late. *Lanashans* had two classes. Mr. Dixon gave Mrs. Lang the cup. In *Hamburghs* the first Spangled (Long), and first Black (also Long's) were good, and the Golden-pencilled of Mr. Cresswell had many merits. In *Polands* the first went to superb Blacks, the hen simply grand (Norwood), and clean through her moult; third also were good Blacks (Darby); and second to Golds (Burrell). *Leghorns* came well to the front, and we thought the awards good. In *Brahmas* the Lights were admirable. Mrs. Drummond exhibited a cockerel, shapely and good in comb, and the pullet of Mr. Crook was a finely-grown chicken. Darks, too, made larger classes than usually they have done of late. In *French* the first Houdans contained a fine old cock (Boissier) mated with a good all-round pullet, and the winning Crêves were Black and large. In the Variety class Silbies were first and third, and Sultans second. The *Bantams* and *Waterfowls* were of great merit, the Booted of Mrs. Holmes being most promising. This lady seems to have quite established the Black-booted, and to have bred out the brassy hackles. We hope Mrs. Crook will be as fortunate with her Light Brahma Bantams, which are journeying along the right road. The Sale classes were well filled, and in *Pigeons* Mr. Jones had a fairly large number to deal with, and performed his work with success. The winning Pouters were good, as, too, were the Turbits. In *Fans* good Whites came first, and the *Dragoons* mustered well, and the winners were highly meritorious. The entries were chiefly made by amateurs, for the great exhibitors were away in Suffolk. We hope this Society will continue to thrive, and that next year they may meet with even greater success than on the present occasion.

THE WESTMINSTER AQUARIUM POULTRY AND PIGEON SHOW.

THIS Show, the second of the kind held in the Aquarium, opened on Tuesday afternoon. The building is admirably adapted to the purpose, and we looked forward to seeing a splendid collection of both poultry and Pigeons. Our expectations were heightened as we read in the train from the advertisement columns of the daily papers, "The greatest Show ever held." We cannot say that the reality quite came up to our anticipation, for neither numerically nor in point of quality is the Poultry Show equal to many provincial shows, though the Pigeons are, indeed, a large and magnificent collection. It is most unfortunate that four great shows should be held in or near London within a few weeks. The season has not been a good one for early chickens, and we much wish that some of these shows could have been deferred to a time when birds of the year can be seen in their proper state of development, instead of being shown now when the pens are filled with a few precociously forced birds and a great many immature chickens. The Bristol Show is, we fear, a thing of the past, and the early days of January in which it was formerly held would be a capital time for an exhibition in London, then full of holiday-makers. This, however, is a suggestion for another year; we must return to the present Show. Its management seems in every respect good, a great improvement on last year. When the doors were opened every bird was in its place, and many classes had their prize cards up, and by five o'clock almost the whole of the awards were announced. The poultry numbered 550 pens, about the number at Ipswich last week.

Dorkings head the list, and are certainly better than the *Dorking* classes at the latter Show. The cup goes to a huge Dark cockerel of Mr. Beachey's, long on the leg, and with a poor comb; we prefer Mr. Burnell's second. Mr. Peel's third-prize birds are square, full-breasted, true Dorkings. The pullet cup goes to a good Coloured bird of Mrs. Lang's; the second Dark pullet looks very antique. The first and second cockerels in the Any other variety *Dorking* class are both good Silver-Greys; the first is the largest; a weedy White is third. The winning pullets are all Silver-Greys, the first very large, and, as well as the second, of the pale-breasted very soft colour.

Cochins.—The cup here goes to Mr. Sidgwick's Buff cockerel, a real canary-coloured bird, young and still chicken-like; second is a very heavily-feathered bird of Mrs. Tindal's; third a rich and evenly-coloured bird, which we thought very good. The first Buff pullet is of the canary hue and well shaped. The cup for pullets goes to a beautiful Partridge belonging to Mrs. A. Tindal. The Any other colour classes are poorly filled, and the specimens by no means equal to some of those we saw at Ipswich. All the winners are White save the third pullet, a good Black.

Brahmas.—The cup Dark cockerel is a massive heavily-feathered bird, rather coarse in head; second will quite be his equal by-and-by. The first Dark pullet is a grand bird, combining exquisite pencilling with fine shape and size; her leg-feathering is a little deficient. The first Light cockerel is a very matured bird, short-legged and of the Cochins type; he

Cock.—1, J. Baker. 2, R. Woods. 3, A. Curtis. *Any other colour or White*.—*Hen*.—1, J. Chandler. 2 and 3, R. Woods. *Young Cock or Hen*.—1, R. Woods. 2 and 3, Withfield. *Blue-chequer*.—*Cock*.—1 and 2, R. Woods. 3, J. Guthrie. *Hen*.—1, J. Guthrie. 2 and 3, R. Woods. *Young Cock or Hen*.—1, 2, and 3, R. Woods.

TUMBLERS.—*Short-faced Almond*.—*Cock*.—Cup, H. C. Henning. 2 and 3, J. Ecroyd. *Hen*.—1, R. Fulton. 2, J. Baker. 3, J. Ecroyd. *Young Cock*.—Cup, H. C. Henning. 2 and 3, R. FOREIGN OWLS.—*Any colour*.—*Cock or Hen*.—1 and Cup, F. Wilde. 2, T. Chambers. 3, J. Ecroyd. 4, J. Sparrow. H. W. Webb. 3, F. P. Bulley.

TURBIDS.—*Blue or Silver*.—*Cock*.—1, E. Walker. 2, R. Woods. 3, S. Salter. *vhe*, P. H. Jones. *Hen*.—1, J. Ecroyd. 2, T. C. Burnell. 3, P. H. Jones. *vhe*, J. T. Herbert. *Red or Yellow*.—*Cock*.—1 and 2, J. Ecroyd. 3, Ridley & Dye. *vhe*, T. C. Burnell. *Any other colour*.—*Cock*.—1 and Cup, J. Ecroyd. 2, O. E. Cresswell. 3, S. Salter. *vhe*, G. Hardy. E. Walker. *Hen*.—1, R. Woods. 2 and 3, J. Ecroyd. *Shell-crowned*.—*Cock or Hen*.—1, J. Ecroyd. 2, O. E. Cresswell. 3, G. Hardy. *Any colour*.—*Cock or Hen*.—1, G. Roper. 2, H. E. Tenney. 3, S. Salter. *vhe*, J. Baker. 4, R. Fulton. G. Hardy. E. Walker. Ridley & Dye.

MAGPIES.—*Black*.—*Cock or Hen*.—1 and Cup, S. Salter. 2, F. P. Bulley. 3, W. Tidd. *Any other colour*.—*Cock or Hen*.—1, G. H. Gregory. 2, S. Salter. 3, R. Fulton.

RUNTS.—*Any colour*.—*Cock*.—1, J. F. Alfaro. 2, J. S. Price. 3, J. Bailly, jun. *Hen*.—Cup, H. Yardley. 2, Lady F. Bushby. 3, H. Stephens.

FLYING TUMBLERS.—*Bald or Beard*.—*Cock or Hen*.—1, J. Brown. 2, C. W. Hobbs. 3, E. Davis. *Any other colour*.—*Cock or Hen*.—1, J. Baker. 2 and 3, H. O. Crane.

BLONDIETTES. *TURBETTES*. *SATINETTES*. &c.—*Cock or Hen*.—Cup, E. Beckwith. 2, H. Yardley. 3, P. H. Jones. *vhe*, R. Fulton.

ANY OTHER VARIETY EXCEPT ANSWERS.—*Cock or Hen*.—1 and 2, E. Beckwith. 3, F. P. Bulley.

SHORT-FACED ANSWER.—*Cock or Hen*.—1 and 3, J. Ecroyd. 2, W. F. Entwistle.

HOMING.—*Cock*.—1, Cox & Norris. 2, J. W. Barker. 3, T. K. Cucksey. *Hen*.—1, J. H. Sparrow. 2, Cox & Norris. 3, T. Comm.

SELLING CLASS.—*Carrier*. *Pouter*. *and Short-faced Tumbler*.—*Cock or Hen*.—1 and *vhe*, H. M. Maynard. 2, K. Cant. 3, J. Baker. *Any other variety*.—*Cock or Hen*.—1 and 2, P. H. Jones. 3, W. Sargeant. *vhe*, J. Baker. *Pair of Birds of any variety*.—1, P. H. Jones. 2, W. Tidd. 3, J. J. Edleston.

FLYING CLASS OF HOMING BIRDS.—*Cock or Hen*.—Cup and 2, J. Edmunds. 3, J. J. Sparrow. 4, G. Carvill. 5, R. S. Pearce.

JUDGES.—Messrs. Hewitt, Teesbay, Nichols, Betty, Hawley, Capt. N. Hill, F. Wiltshire, F. E. Esquilant, and F. Graham.

IPSWICH POULTRY SHOW.

THIS excellent Show of poultry and Pigeons was held in the Corn Exchange. The Ipswich Committee are all real fanciers, and under Mr. Wragg as captain they brought their show to a most successful issue, and as they for the first time introduced the plan of having amateurs as Judges an immense amount of interest was taken in the awards. Mr. Horace Lingwood judged the Brahmas and Sale classes; Mr. Mathews the Malays, Game, and Game Bantams; Mr. Felton the Cochins; and Mr. Cresswell the remainder; and we heartily congratulate each gentleman upon his awards. The Committee were most anxious for the welfare of the birds and exhibitors, and we did not see a bird wrongly penned from any blame of the attendants, and never, we think, saw fewer empty pens.

Dark *Brahma* cockerels opened the catalogue, the winner going to Stoke Park—a well-growing bird of good feathering and sound colour. In Dark pullets the second was perhaps the best in markings and colour, but she had too much hack feather for Mr. Lingwood's fancy. Light cockerels were excellent and the winners admirably chosen, though we doubt if the Judge was as happy in his selection of Light pullets. We did not care for the winner, who was puffy in body and ungainly in her movements. The second and third were very good, as was the pullet of Mr. Dean. Lady Gwydyr showed a good one but younger. Buff *Cochin* cockerels followed. Perhaps second or third were in the best feather and of soundest colour, but the cup bird was very broad and large and pretty in head and feet. This bird, we believe, is to cross the ocean in a few days. We liked the three winning Buff pullets very much, and there was little between them; the third, however, had no tail and a little black in her neck. Partridge cockerels were good, the first the most

up; and in pullets a bird lovely in pencillings walked in first; second was also good, and then came a great difference between her and the remainder. White cockerels were good, the winner the older, or else not very shaven in tail. In White pullets the first won the cup; she was a big bird and good all round. Second a little in need of a bath, or else very good; and the third a neat pullet. Black cockerels were also young, as were the pullets, but the latter class was large and of great merit throughout, the cup bird beautifully feathered and bright in bloom.

Dorking cockerels were all good, the cup bird excelling in head, colour, and shape. In pullets only the two winners deserve notice. The second here again younger than the first, but of more future promise. In White Dorkings we liked the first pullet very much; the first and second cockerels were also good and of nearly equal quality. In *Spanish* only the cup cockerel was good; he had a nice head and smooth face. The first *Minorca* (Black) cockerel was fair, but the class miserably small. In *Game* Mr. Martin's Brown Reds were splendid. This gentleman, too, showed some good *Duckwing* cockerels, one of which was claimed for £10 10s. A good *Pile* was second in the Variety class, and the first Black Red cockerel was stylish and good in feather. In *Malays* the cup went to the cockerel, a good all-round bird, but not very large. The first pullet was big and good in bone, with proper carriage. *Hamburgs* mustered well. The cup went to the Gold-pencilled cockerel, a prettily tailed bird and bright in colour. The first *Silver-pencils*, first *Silver-spangled* cockerel, and the winning *Blacks* were all good, and we quite approved of the Judge's selections; we believe, too, all were satisfied, which in such competition is satisfactory. The *Polands* were very meritorious, the cup going most deservedly to a superb *Silver* pullet, large in crest and perfect in marking. The first cockerel was a Black, a good showy chicken, and we are glad to see how this breed has come to the front of late.

The *French* divisions were large, and on all sides we heard Mr. Cresswell congratulated on his awards. We never remember seeing better *Houdan* pullets than the first and second. They were as excellent in markings as the late Mr. Dring's and Mrs. Vallance's old hens, which won so much. *Crêves* were good, and the awards were well made. We suppose Mr. Horatio Stephens has again bought, for we believe we saw in his pen the first *Bath* pullet of Miss Williams! *Leghorns* were better than usual, and we observed a Cuckoo-coloured specimen which looked rather pretty. The prizes in cockerels all went to Whites, while in pullets a White came in between two exceedingly white-eared Brown pullets. The Variety class contained some good *Silkie*, Cuckoo *Cochins*, and *Sultans*, all of which made their mark in the prize list. *Game Bantams* were meritorious, and in the Variety class a pen of Black-booted won first. Mr. Leno's *Silver-laced* were of high quality and won the cup. The *Waterfowl* were attractive. The *Aylesburys* capital, and useful-looking *Rouens* won the cup, while in the Variety class *Pekins*, *Whistlers*, and *Spotted-bills* won in the order named. *Grey Geese* won all the prizes, and in *Turkeys* we liked all the three prize pens, the third being best in colour though the smallest. In the Selling class were some good Buff *Cochins*—a White pullet shown by Mrs. Holmes, a good *Partridge* cock exhibited by Lady Gwydyr, and several other fair birds, but we did not notice many sales by the time we left, at two o'clock on the last day of the Show. We have only to mention, in conclusion, that the birds were dispatched very quickly at the close of the Show, and we have heard of many birds which reached their owners early on the following day. The prizes for Pigeons were also awarded by amateurs.

MARKET HARBOROUGH POULTRY SHOW.

THE Northamptonshire Agricultural Society met this year at the above town, and the show of poultry was certainly the best we ever remember to have seen at this county's meetings. Mr. Dixon awarded the prizes and gave satisfaction to all. The first class contained nine *Dorking* cockerels, and the chosen one was a large Silver-Grey, a beautiful pullet in the next class of the same colour taking the place of honour from among nine more pullets. White *Dorkings* were very good, the three winning pullets being especially fine. *Spanish* cockerels were moderate, the winner not very firm in his comb, but otherwise good. *Game* made fairly good classes, but beyond the winners there was no striking merit. Buff *Cochin* cockerels only produced a pair, both moderate, but the pullets were better, while the Whites were excellent. The second cockerel was rather white in ears, or else the largest; and in pullets the winner was well in first. Dark *Brahmas* brought but ten entries in two classes, but the first pullet was well marked and of fair size. However, the Lights were of great quality, and we much liked the first cockerel as also the winning pullets. The *Hamburgs* made an average collection. The first Silver-spangled cockerel was very good, as was the first Silver hen. Both seconds in Spangles went to Golds; and in pullets and cockerels (pencilled) Silvers won both firsts, and Golds again the two seconds. In the third Golden-pencilled pullet we believe we recognised the second Bath bird. In the Variety classes a good Black *Hamburg* cockerel very forward in feather came in first, while a capital *Crève* won first in pullets. In *Bantams* excellent Silver-laced won both the firsts and seconds, and Black Reds both the thirds, but there were only three pens in each class. Pekins won first in the Variety class for Waterfowl, and Whistlers were second. The first *Aylesburies* were good in bills and large, and the same remark applies to the *Rouens*. The first *Turkeys* too were excellent, and the catalogue tells us they were only hatched on May morning.

In the *Pigeon* class, which had fourteen entries, a beautiful Almond was first. Third was a White Pouter, which some thought should have gone before the second Barb. An extra prize was given to an Owl, and an extra fourth to a neat Jacobin. The awards were—

POULTRY.—DORINGS.—Silver-Grey or Coloured.—Cockerel.—1, R. A. Bossier. 2, E. Snell. 3, B. Hanbury. **Pullet.**—1, R. A. Bossier. 2, E. Snell. 3, O. E. Cresswell. **Any variety.—Cockerel.**—1, E. PIGEONS.—Cock or Hen.—1 and 4, H. Yardley. 2, L. Watkin. 3, T. Chambers. 5 and 6, T. W. Swallow.

CAYUGA DUCKS.

NEVER having kept Ducks until last year I do not think I am able to give an opinion as to their paying, but I must say the rapidity with which these Cayuga Ducks grow and fatten on very little food (compared with fowls) is marvellous. I was unable to keep a strict account of mine last year, but I gave a pair to a lady, and the Duck laid fifty-two eggs before sitting, and afterwards eighteen more; seventy in all.

For the table I consider they far surpass Aylesbury or any other tame breed of Duck, the flesh being far less oily and flavour more like wild Ducks. Their plumage is extremely beautiful, but any white feathers are a blemish; they should be black with a green metallic lustre.—G. M.

PROLIFIC DUCKS.—Mr. J. Bate, of Michaelstow, Cornwall, has now in his possession two Ducks, a cross between the Aylesbury and Rouen, which by the time they were fourteen months old had laid the following number of eggs:—One laid 189, ten of them being double yolks, and laid six in two days, the shells of all six were hard but not perfect, and laid fifty nights in succession; the other laid 161 eggs during the same time, and fifty-eight nights in succession.

DRIVING AND UNITING SWARMS.

THOUGH the process of driving and uniting bees has been often unfolded and discussed in our columns, I receive private letters from parties who have failed in their attempts to drive bees out of their hives, and in these letters many questions are put as to the cause or causes of their failures. As the process of driving is simple and known to be successfully practised by hundreds of apiarians, the parties who fail in their first efforts naturally want to know why their bees would not run. Whenever and wherever failure happens there has been in some way or other non-compliance with the conditions of success. We can come to no other conclusion. In cold weather bees are loth to leave their hives. Small swarms sitting in the centre of their combs are loth to leave their warm nests, and would rather not touch the outside combs or travel over them. Some hives again are only partially filled with combs. When these hives are inverted their combs stand in their centres like little cones, with their points at the farthest possible remove from the sides of the hives. During the drumming process bees naturally run upwards, and if they be driven to the tops of the pyramids of combs they can find no pathway to a higher region. When bees run up to the points of such combs and can get no higher no amount of drumming will dislodge them; but give them a ladder of some kind by which they can reach the upper hives and a very little drumming will cause them to run up. At certain seasons of the year, and September is one of them, some kinds of hives are damp or wet on their inner surfaces, and bees do not like to travel over them. The empty hives into which bees are to be driven should be dry and warm, for bees are not easily driven into cold damp hives. Other things that hinder bees from running from one hive to another in the driving process might be mentioned, but we think enough has been said to convince the reader that when bees do not run the fault is not in the principle or system, neither is it owing to the stubbornness of the bees: the fault must be in the application of the principle. The conditions of success should be well considered and understood, and whenever driving begins it should be done with vigour and without halting; the drumming should be stunning and startling enough to confound the bees and make them run without halt or hesitation. In cold weather it is advisable to sprinkle the bees with syrup about an hour before they are driven. At the end of an hour after the sprinkling the heat of the hive is much higher, and the bees are full of life and activity and quite ready for action.

In seasons like the present one, when hives are light and easily handled, we shake our bees out of their hives by a speedier process than that of driving. An hour after feeding them the bees are found setting very loosely amongst their combs. We then lift the hive gently off its board and balance it on our hands in its natural position over an empty hive. By giving the hive a sudden jerk or shake the bees are cast into the empty one. The hives have cross sticks in them, and therefore their combs are not easily shaken loose. Often we cast the bees from their hives by lifting them 2 or 3 feet and letting them drop on the mouths of the empty hives. Both hives and bees are put in motion by the law of gravitation, and when the empty hives stop the full ones, the bees go forward and fall on the bottom of the empty hives. We have not once this year resorted to the driving process in removing bees from their hives, save in the time of swarming. The bees of condemned hives were shaken and thumped out in the way described above. With bar-frame hives whose combs are moveable the bees may be easily and speedily removed from their combs by a handbrush. With such hives both driving and shaking are unnecessary. We would lift the combs out one by one and sweep the bees into an empty hive. After the crown board has been removed ten bars of combs covered with bees may be swept clean by a handbrush in a few moments.

After bees are driven or shaken out of their hives they are generally united to other stocks with a view to make them stronger. This practice cannot be too strongly recommended, and the art of uniting bees cannot be too carefully studied, for bees naturally resist invaders, and if fighting begin a fearful slaughter takes place in a very short space of time. I have seen whole swarms, containing I daresay twenty thousand bees, killed in less than an hour. The bees of the hives receiving the swarms are the butchers in these cases; very few of their own ranks are lost in these slaughterings. Failures in efforts made to unite bees result from non-compliance with some necessary preparation or condition. Strategic movements are necessary here as well as on the battlefields of contending armies. If the city is to be invaded the citizens must first be put off their guard; fill them with hilarity and joy, and put all in a state of excitement and merry-making. Good sugar syrup given in a warm state will do this. As bees know strangers by smell, it is well to prevent them from knowing strangers or invaders during the uniting process. This is done by the presence of some over-mastering substance, such as crushed mint or grated nutmeg. By feeding both swarms with syrup strongly scented an hour before uniting them, and sprinkling all after they are cast together, the union may be effected without the loss of a bee. Careful and wise generalship in the union of swarms will prevent all slaughter. The best time to unite bees is after sunset or later in a dark room or cellar, and replacing them in the garden before daylight next morning. If the hive which is to receive the swarm has no brood in it its bees could be driven into an empty hive and there kept for two or three hours. Meanwhile the other swarm could be cast amongst the combs, and afterwards the bees that were driven from them. This is rather a laborious mode of uniting bees, but it is a safe and successful one, for both swarms are cast into the city as strangers and have nothing to defend. A few days ago I had a swarm of bees weighing 4 or 5 lbs., which I divided into three lots with a view to strengthen three hives standing close by. Minted syrup was given to the hives half an hour before the bees were given to them. Two lots were well received, but in the third hive the invaders were attacked at once, and would all have been slaughtered in ten minutes if I had not shaken all the bees out into an empty hive. They were all strangers in the empty hive without disposition to fight. In the empty hive they fraternised and cemented a lasting union, and amid peace and good will they were cast back into the hive of combs from which they were dislodged.—A. PETTIGREW.

BRITISH BEE-KEEPERS' ASSOCIATION.—At the Paris International Exhibition in 1873 a large amount of space has been allotted to the above Association, on which their members may exhibit the British apian manufactures.

OUR LETTER BOX.

BATH, GRAYVILLE, WEYMOUTH, AND IPSWICH SHOWS.—Mr. Tomlinson informs us, that having sold the birds he intended exhibiting at the above Shows, his entries were not filed.

MANAGEMENT OF BRAHMAS (Anxious).—We disapprove your feeding. We dislike sharp, maize meal, and potatoes. The first is not so good as barley-meal. We never could induce our birds to eat the second. The third invariably causes disease of the liver. The grass may lessen these ill effects, and the birds seem to know it. Give them barley-meal slaked in the morning; whole corn, maize, or barley, or, if you can, kitchen scraps at mid-day, and slaked barley-meal in the evening. You will find them improve in weight, feather, and appearance. No mistake is so great as to feed on inferior food for economy's sake. If instead of measure you bought your food by weight you would generally see the most expensive food was the cheapest. You can, of course, try it by weighing, but a test is always at hand.

Take a small quantity of barley and put it in water. The expensive, if it be worth its cost, will almost all sink to the bottom; the cheaper will cover the surface of the water with light grains and rubbish.

DARK BRAHMA AND HONDAN CROSS.—"C." asks, to produce good table fowls, whether to use a Dark Brahma cock for Hondan hens, or a Hondan cock for Brahma hens, having regard both to quality of meat and early maturity for the table, as well as weight?

WASPS ENTERING HIVES (B. S.).—Wasps do not cause bees to leave their hive. Your old hive has been lost from some other cause, probably the loss of its queen. After bees have lost their queen they gradually wander away till none remain. Sometimes both bees and queen leave a hive—go off together as a swarm—from sheer starvation or from the intolerable stench of foul brood. It is not at all likely that the bees of your deserted hive entered any of your other hives. If they had attempted to do so they would probably have been killed at the door. All you can do to prevent wasps from entering your remaining hives is to contract their doors and thus enable the bees to defend their hives. Wasps never master the bees of healthy hives, though they occasionally enter them when sentinels are not on duty. The bees of healthy hives are so large and courageous that wasps dare not meet or face them in open combat.

WEAK HIVE (Norfolk).—The swarm you hived at the end of August, and which has not made much comb, is very weak indeed. If the few combs it has made are not covered with bees you would have great difficulty in keeping it alive till spring. Your better way will be to unite the bees of this weak hive to the other hive, for it, too, is doubtless in a weak state by reason of its swarming so late.

REMARKS.

- 19th.—Dull and grey all day and all night; no sun at any time during the day.
20th.—Dull and rainy at times, very dark all day till 5 P.M.; after that time much finer. Curious radii from the moon between 9 and 9.5 P.M.
21st.—Very bright morning, short sharp shower at 1 P.M., hail at 2.15 P.M.; fine afternoon and evening.
22nd.—Very fine and bright all day, but rather cold.
23rd.—Dull morning, but soon clearing off; dark for a short time about noon, but fine afterwards, though cold.
24th.—A very fine autumnal day, dry and bright, but rather cold.
25th.—Hazy in early morning, bright forenoon, rather dull in afternoon, and hazy after sunset.

Temperature generally about 7° lower than that of last week, partly owing to the absence of sun, and partly to the prevalence of north-westerly winds.—G. J. SYMONS.

COVENT GARDEN MARKET.—SEPTEMBER 26.

A VERY general decline has taken place in the value of foreign goods, owing to the large quantities reaching us consequent upon the high prices realised last week, otherwise there is very little alteration to quote. Kent Cobs have sold well, and with a good supply have maintained their value. Trade generally quiet.

From observations taken near London during forty-three years, the average day temperature of the week is 61.0°; and its night temperature 42.4°.

GENERALISMS ON MILDEW.

CORRESPONDENT on page 191 of our Journal bewails the uncontrollable ravages of mildew among his Roses, and, while asking for further information, gave a number of so-called preventives and cures, which on being put to the test proved in each case, if not complete failures, yet most unsatisfactory in the general result.

The writer of the following lines, as a sufferer year after year from the same widespread cause, gladly hailed the appearance of a paragraph in the Journal headed, "Rose Difficulty." At last, he thought, I shall obtain some practical information—some probable solution of this mysterious visitation, even if a perfect cure were not to be expected; but, alas! no. The "CITY CLERK," an unmistakably zealous but inexperienced brother horticulturist, merely states his grievance, and then puts a varied string of questions, which doubtless some other correspondents will answer *seriatim*.

Perhaps, as no one has taken up as yet the subject, the following generalisms as to the nature, object, prevention, and cure of mildew may not be wholly useless. Few horticulturists of the present day require to be reminded that mildew (called after two Saxon words meaning meal dew) is in its true character a plant, a vegetable parasite; and although at the beginning of the present century its ravages were attributed to blight, honeydew, or diseases in the plant itself—to any source rather than the real one—attacks of myriads of destructive fungi, yet its fearful effects as causes of famine or pestilence both biblical and classical literature in the time of the Jews and Romans, and nearer our own time in the Middle Ages, conclusively hand down to us.

There are three different kinds of mildew—1, affecting superficially the leaf; 2, the interior of the stem or leaf; and 3, the root. It is with the first of these kinds that our gardens are mostly attacked; it may be added *en passant* that, as a rule, though not always, each species of plant has one special species of fungus at least peculiar to it.

It is of melancholy interest to notice here that of the four sub-orders of the great natural order Rosaceæ, three (one is entirely tropical) are specially liable to attacks of fungus or mildew in some form or the other. No. 2 sub-order, Chrysobalanæ, gives us through the Almond tree our Peach and Nectarine, both fruit trees, especially the former, in many situations annual victims to this pest. No. 3 sub-order, Rosæ, gives us (nursed originally in the cradle of the Dog Rose, through Rosa Gallica or Provens Rose and our old Centifolia or Cabbage Rose), the queen of flowers, alas! so often disfigured and injured by the same fell influence. No. 4 sub-order, Pomeæ, gives us among edible fruits the Apple and Pear, which suffer terribly under periodical visitations from several parasitical fungi peculiar to them.

I may mention here, in answer to the "CITY CLERK'S" question as to whether the disease on the back of the

Laurel leaves, very prevalent now in Surrey, is the same as Rose mildew, that, unusual as I believe the circumstance to be, most probably it is; at any rate the same phenomenon was observed last July in Herefordshire by several reliable individuals, where the leading shoots of neighbouring Apple, common Laurel, and White-thorn trees were discovered to be infected with precisely the same parasitical plant or fungus, first appearing as a white, but changing afterwards to a rusty-coloured mildew.

The appearance of mildew takes the form generally of white or black spots on an uneven patchy surface either as a rusty powder or frosty incrustation, in every case spreading unless checked in an early stage, and by preventing respiration crippling the growth of the flower or fruit, and causing the leaves to fall, if not the plant itself to die.

The usual period for the appearance of this widespread pest (for it is co-extensive with all animal life) is in the autumn, as with all other fungi, and it is far easier to speak of the causes that produce them than of their prevention or cure. The rapidity with which they arrive at maturity and the enormous number of seeds they produce is something incredible. One great analytical mycologist (Mr. Worthington Smith) could tell us, so as to allow us to realise some approach to the aggregate number produced, that one Mushroom was sufficient to propagate 250 millions; while only twenty-four hours is necessary with some fungi to intervene between the first springing of the plant and the ripening of the seed.

It should be remembered that it is the first kind, or superficial mildew, alluded to here, which, being as seeds communicated when ripe to the air, establish themselves on one plant after the other wherever they touch, destroying the plant with which they come in contact, as has been stated, by preventing respiration. All this is the unanswerable outcome of observation and experience, and as such matters of fact. Would that the prevention and cure of mildew could be as easily and satisfactorily disposed of.

Dr. Lindley—and his authority carries great weight—considered that as "plants are generally most affected by superficial fungi after a long drought, when the fibres of the roots are unable to imbibe sufficient moisture from the soil, and the plant becomes debilitated and affords an easy prey to the parasite which attacks it," the cure seems to be abundant watering, and assigns as a proof that in Scotland where there are heavy night dews this fungus is unknown. But surely, especially when viewed at such a humid season as the present, the subject is still left open, and many other agencies still to be considered accountable for the production of fungi besides drought. The view which seems to meet more fully the whole circumstances of the phenomena is that changes are undergone, as in the case of the Potato disease, in the cells and vessels of the leaves, say of the Rose, by cultivation (how seldom does one see mildew under any circumstances on the Dog Briar), which render the plant liable to disease: atmospheric influences, such as sudden

transitions from heat to cold, long-continued drought, or wet, as in the present year, are thus enabled to act upon them so as to cause alterations in their condition of health. Thus the attack of fungus accelerates the morbid action of the plants, which practical experience and science are alike unable to prevent or cure. Dr. Greville gives it as his opinion that "as the production of mildew is probably the result of a peculiar state of the atmosphere, there is little chance of any means being found for its prevention."

Close observation for many years leads the writer to dread the ravages of mildew most in the beginning of spring and in autumn—in the rising and ebbing of the sap—seasons when even under normal conditions the Rose under cultivation is peculiarly sensitive of variations of temperature. If healthy but not too strong plants at starting, close pruning, especially Roses on *Manettis* according to sorts, great care in not over-manuring, especially in a wet season like the present, or manuring either under ground or top surface-dressing with raw or green manure; judicious choice of situation, especially as regards free circulation of air; deep trenching, according to the nature of the soil; frequent hoseings, and copious waterings with soft water, and heavy mulchings in arid exhausting soils;—if expedients like these fail to meet the difficulty of the case (and in the writer's case and your correspondent's already alluded to they have failed), then he must confess he knows no other; for such applications as sulphur pulverised or in solution, or soot, he utterly abhors on the ground of the remedy being worse than the disease; so he will content himself with waiting for an occasional propitious season, and meanwhile keep looking through the pages of successive Journals in the fond hope of finding some successful nostrum for the prevention and cure of that hateful pest mildew, certainly not known as yet to the—HEREFORDSHIRE INCUMBENT.

OUR BORDER FLOWERS—LILYWORTS.

THE time is at hand for our selecting bulbs for the decoration of our borders, spring gardens, and other places where we may choose to place them. Various as the kinds of plants are for this purpose, I would invite attention to the family of Grape Hyacinths. They have been far too long in the background. Being natives of more genial climes than ours we may not see them in all their beauty, yet some of them have long been occupants of our borders and done us good service during the spring and early summer. We may not be favoured with such sunny skies as those charming plants enjoy in their native homes, yet we welcome them for their beauty and their fragrance. They are a very accommodating race, equally interesting in bed, border, rockery, or pots, for in or out-door decoration, and are invaluable for bouquets when to be had thriving in any ordinary garden soil. The lovely white colour of some of them, and the beautiful deep sky blue and rosy purple of others, with their delicate perfume, is a sufficient recommendation for their extensive cultivation, and being cheap withal they come within the reach of most cultivators. They may remain in the same place year after year, and will bear a good deal of rough usage into the bargain. If it is desirable to increase them the bulbs may be separated after they have perfected their growth, but they are just as well left alone. Any of our importers' lists will afford a good opportunity for making a selection and forming a collection.

For pot culture they succeed with the same treatment as the Hyacinth. Half a dozen bulbs in a 5-inch pot afford a charming display of flowers. One of the most interesting of the family is the Feathered Hyacinth (*Muscari monstrosum*), its curious frizzled cluster having a very striking appearance; it lasts a long time in flower and ought to be in all collections. *Muscari racemosum* is a very attractive plant; *M. neglectum* is still more beautiful; then we have *M. maritimum* (luteum), a real gem and deliciously perfumed; *M. candicans* with its beautiful white bells in pendant form is also an acquisition; *M. Heil-drichi* (pulchellum) is a charming plant, the queen of the race. There are many others worthy of cultivation, and which will repay any amount of care bestowed upon them.—*VERITAS*.

THE ROSE ELECTION.

THE declaration of the poll has come at last. What will it be? Will it satisfy everyone? Certainly not! Did it achieve this wonderful result, I myself should be the first to say it was useless. The old Latin proverb applies to Roses as to all other things—different men have different opinions, and if in

matters generally, why not in Roses? They suffer according to climate, they are grown in different soils, they have varying treatment. Necessarily under such circumstances the opinion of their merit here and there must differ. The election at any rate has this effect, no insignificant one—it shows from a variety of sources collected together the general opinion of their merit; and now that I have divided the merit into first, second, and third grades, it makes it the more improbable that two Roses will appear bracketed together; and the first forty-eight on the list will represent, at any rate for the present, the general opinion of the best exhibition Roses.

What, it may be asked by some, constitutes a good exhibition Rose? Dare I attempt to answer this? I can only give my own ideas. They are these: In equine matters there is an old saying, that a good horse is never of a bad colour. In Roses I would alter this, and say that the best-coloured Rose cannot compensate for bad form. It is essential, it seems to me, that in a stand say of forty-eight *form* should be the first requisite. Sometimes for the sake of diversity of colour we may, perhaps, give up the greater for the lesser attribute, but to me it would not compensate for deficiency in form. A tyro in Rose culture may perhaps imagine that a good-formed Rose in Devonshire, for instance, with its genial air, would retain its beauty of form in some of the bracing spots to be found in Wiltshire. Differences of soil and climate affect in a great degree the form of our favourites, and so one of the electors writes—"I can never depend here on Comtesse d'Oxford or Eugénie Verdier to exhibit, as they always show their centre sometimes during the day of exhibition, even if they are perfect at the time of judging, so I have not put them in my list." *Maréchal Niel*, one of the grandest-formed Roses when in perfection, has some seasons with me been hopelessly deficient, never, however, to the extent that seems to have attended the efforts of my friend Mr. Parsons of Frome, who writes—"I have now grown that Rose (*Maréchal Niel*) for many years out of doors and under glass, worked on all sorts of stocks, placed in every situation I can command, and yet I can safely say that I never yet had a bloom that was a pleasure to look at, still less one fit for an exhibition stand." This opens-up a subject to which I shall revert presently. To return to a good exhibition Rose. Next to form I should place *substance*. By substance I mean texture of petal. This should be firm and stiff though fine in quality. How many of the lighter-coloured Roses fail here, especially among the Perpetuals! *La France* on some stocks and in some situations; whilst *Comtesse de Serenyi*, *Miss Ingram*, *Duchess of Edinburgh*, and many others are soiled and injured by bad weather. In this particular no light Rose in my opinion equals *Baronne de Rothschild*. Next I would place *colour*, and lastly *stuff*. I only place this last because a good form will often hide deficiency of stuff. Some of our very best Roses would be all the better for additional petals.

And now to the subject alluded to above. Should the lists returned be the experience, each in his own situation, of each elector? or should he be allowed to enter in his lists Roses which, failing in his own, may yet attain the greatest perfection in a neighbour's garden? If another exhibition is ever carried out this point ought to be settled. Personally I consider the former the correct course, but I am afraid that some of the electors have thought differently and acted on it. The utility of these elections, it seems to me, is to show intending purchasers what in all the varying soils and climates of our isles are generally the best. If, then, an elector gives a vote founded on the experience of others this result is in some degree defeated. But I fancy I hear some enthusiastic and ardent worshipper exclaim, Let us have the state of the poll.

This requires a little longer explanation. The first column gives the position of the Rose named; next comes the name of the Rose, its variety, year of introduction, and name of raiser; * then follow the columns headed 1, 2, 3, representing respectively the votes obtained by each Rose in the first and second twelves and next twenty-four given by amateurs, then the total of such votes; the same numbers with an asterisk denote the same votes given by nurserymen; lastly, the grand total represents the whole votes received by each Rose from both sections of voters.

It is only necessary further to add that the position of any

* This list is now very nearly complete. It has been a great addition due to the working-out of the Rev. C. P. Peach's idea, and I think all growers of the Rose are indebted to him for the suggestion. There are still missing links which I should be glad to fill up; and there may be errors, for which I apologise beforehand.

Rose is decided first by the total number of votes it has received. Supposing two are equal here, then by the greater number of first-class (first twelve) votes; if still equal, by the greater number of second-class votes; failing here, they are bracketed together.

I meant to tabulate seventy-two, but the last three named must, to use a Wimbledon phrase, shoot off the tie when the competition opens again. Five Roses received eight votes, three seven votes, three mustered six votes, seven were mentioned five times, twelve four times, amongst these being Cloth of Gold with two first-class votes, eleven found three supporters, no less than twenty-five were only named twice, and to close the list, fifty-two received only a solitary vote.

All the electors are prizetakers; there are yet more whose names we should like to see, especially among the trade. Why the trade stand aloof as a body and decline to help puzzles me. Surely it cannot be that, like a village butcher,

they decline to part with a sirloin unless some of the coarser meat be also taken! I doubt whether this pays in Roses, for a man starting in Rose-growing who obtains a lot of worthless varieties is very apt to be disgusted and "throw up his Rose sponge" at once, and decline to invest further. There is another reason why I consider it bad policy for the trade to hold aloof. It is possible that amateur rosarians may reason thus: "I shall give my orders in future to those who assist us to form an opinion of Roses." It appears to me a natural result. In any case it is not, to my thinking, in accordance with the kindly feeling that the love of flowers should produce, that members of the trade should first decline to assist these elections and then advertise their ability to supply the plants that such elections have brought out as useful.

But having this year obtained our qualified electors, has it given us a more valuable result? It must be remembered in comparing this with previous elections that we have also limited the list of Roses by distinctly requiring the best exhibition varieties. It appears to my thinking that both in the first and second twelve there is no question that we have obtained a first-rate article. Both the twelves are very good, and a good stand either of the twelve or twenty-four would be always a pleasure to look at. I fear the result will scarcely please our good friend "WORLD SAVAGE," because in spite of its being an exhibition election by prizetakers the Teas are but poorly placed—Catherine Mermat No. 20, Marie Van Houtte No. 31 (I tremble as I write it), Devoniensis No. 34, Souvenir d'un Ami 37, and Souvenir d'Elise 39. In last year's election there were eight Teas in the first forty-eight. What will our Tea worshipper, or totaller I had almost written, say to this? It is perfectly true that Marie Van Houtte has made a grand jump from 44 to 31, but as a counterpoise Devoniensis in my eyes and in my soil and climate is worth all the —. But I dare not finish the sentence. I hear the rumble of the distant thunder, and like the Rose I don't like storms. But here a word to my brother amateurs. How is it that that lovely Rose has fared so badly at your hands? Glance at the list. Thirty-two amateurs only give Devoniensis thirteen votes, whilst fourteen nurserymen give it exactly the same number.

Beautiful as are the Teas, especially when partly open, I am heretic enough to say that to my eye (the fault is there, no doubt) when more expanded they often lack form. They want, in fact, to "dress-up in the centre;" many would be improved by more petals, and then, alas! when they have them, like Isabella Gray, America, and others, they often decline to unfold their charms. So I am not surprised at their position on the poll. Dear old Gloire "fat, fair," but, oh! sadly beyond "forty." I like the flavour of Tea enough to regret seeing thee No. 59. It is, indeed, a fall from 23 to 59, a fall which I cannot help saying thou dost not deserve. Query, Given the same amount of attention and care as many other Roses receive that do not give us anything like so bountiful a return, and I cannot help thinking thou art worthy of a place in the forty-eight!

The position attained by François Michelon does not surprise me. I ventured some years back to hazard the opinion that it might wrest the premiership of its year from Etienne Levet. This is the first year it has done so, but it will not surprise me to see it still higher. Some of the late introductions have forced their way early into the forty-eight, notably Mons. E. Y. Teas, Comte de Serenyi, Sir G. Wolesey, and Star of Waltham, and it is pleasant to see to two of these Roses the names of English raisers. Of the raisers it may, perhaps, interest some to analyse the forty-eight. They will find, I think, Lacharme and Eugène Verdier credited with nine each; Guillot fils, five; Guillot père, three; Levet, Pernet, Paul and Son, and Granger with two each; whilst the remainder have each one representative.

Out of the forty-six electors Mr. Walters in his list names forty-three out of the forty-eight that ultimately head the poll, whilst no less than twelve name thirty-five, the numbers gradually diminishing till we end with Mr. Scruby, who names twenty-seven. Altogether 191 Roses have been mentioned.

In concluding this portion I tender my warmest thanks to all who have assisted me by their lists. Many also have thrown out valuable suggestions. To one and all I say fervently, My hearty thanks.—JOSEPH HINTON, *Warminster*.

NEW STRAWBERRIES.

I FRUITED Traveller and Exquisite Strawberries two seasons—namely, in 1876 and 1877, and being such a complete failure

the first year had them layered in pots, and gave them a second trial this season in a different soil with no better result, and was much surprised to see them so highly praised in your Journal. We found them insignificant in size, not of the best flavour, with but a very moderate crop, while other sorts were in all respects excellent. Some other new varieties are so much inferior to many established kinds that we have not inserted them in this season's list, and they will soon follow Traveller and Exquisite.—CHARLES TURNER, *The Royal Nurseries, Slough*.

SHELTER FOR BEDDING PLANTS IN WINTER.

A CORRESPONDENT, "R. F. B.," asks for advice about makeshift contrivances for keeping Geraniums and certain other bedding plants in winter, and wishes to know if they may be wintered in a cellar, as he reads has been done. There are no doubt numerous other readers of the Journal requiring advice of a similar nature at this season of the year; let me therefore try to render this reply as comprehensive as possible, and first as to keeping Geraniums in a cellar. Now, I have seen cellars in which this could be done perfectly, for they were dry, had ample light admitted through glazed windows, and were not more than 7 feet below the surface; the Geraniums planted thickly and firmly in boxes, having no water for months, and requiring no other care than an occasional clearance of decaying foliage, keeping plump and tolerably green, yet losing most of the smallest roots—an evil soon remedied when warm weather returns and water is given again. Will my friends look about them and see if they have a similar apartment?—not necessarily a cellar so long as it is not very damp, is tolerably well lighted, and is either frost-proof or possesses facilities for the exclusion of frost. But if no such place is available I can hold out no hopes of success in a dark cellar, for to tie up Geraniums in bundles and put them aside till spring is, to say the least, a very speculative affair, and I much fear very little vitality would be found in any of them—certainly I cannot recommend the plan.

It is matter for regret that when means for winter shelter are not available undue prominence is given to Geraniums, there being so many other flowers wherewith a garden may be made gay, and which can be kept in a dormant condition throughout winter or easily protected, or, better still, be raised from seed in spring—all three methods answering "R. F. B.'s" wish "to have done with them until spring."

Among plants which may be said to lie dormant, tuberous-rooted Begonias are beginning to take a prominent position. Here in the sunny south they are left undisturbed in the beds with a covering of coal ashes or litter to keep off frost; but as "R. F. B." hails from Windermere, he and others farther north will probably succeed best by removing the bulbs from the beds into a cold frame half filled with coarse sand and coal ashes, in which the bulbs should be buried till spring, the frame being placed upon a high sheltered position where water cannot accumulate, and rough litter thrown over to exclude frost. Next come Fuchsias, sometimes left in the same place for many years. The best plan, however, for general purposes is to take them up in autumn with plenty of soil about the roots, place them close together at the foot of a wall, fence, or any sheltering nook or corner, covering them with a heap of leaves or other rough litter, and leaving them undisturbed till the return of genial weather prompts us to plant them once more in beds of very rich gritty soil for a summer display. Then there are Cannas, holding an important position for a variety of decorative purposes, and which may be treated precisely similarly to Dahlias, or, as is now the general way with the more hardy varieties, be left undisturbed for two years, with some coal ashes thrown upon the surface to exclude frost, only lifting and replanting the roots in fresh rich soil in the spring of the third year.

Calceolarias have been so much written about that it seems superfluous to add anything here, further than to note that now is the time to insert cuttings in any unheated frame or pit, watering well and shading upon bright days for a week or two, afterwards as they begin growing withdrawing the lights and exposing them fully to the air upon every fine day, taking care to cover in frosty weather. Verbenas have been wintered successfully in a similar manner, but it is questionable if it could be done in northern districts, where the snow frequently lays so long that the coverings remain on for weeks. Yet much may be done by having the pit in a snug sunny corner well sheltered from cold winds, so that every hour of genial warmth may be turned to account, it often being possible to

remove the mats and litter and open the lights, even when every surrounding object is covered with snow. The success of any such attempt to winter Verbenas will much depend upon having the plants sturdy and well rooted by October. The scarlet Lobelias are not half so much grown as they deserve, yet nothing can be more striking than the dark crimson stems and foliage surmounted by spikes of brilliant scarlet flowers. They are easily wintered by removing the stems when the flowers fade and transplanting the stools to a frame, excluding frost and keeping a close watch for snails. The crowns are divided in spring. Pentstemons may be wintered as easily as Calceolarias, and do well in the north. And then there are Violas, northern plants *par excellence*; how easily they are grown, and how beautiful they are in a moist cool climate!

Thus much for means of protection, the successful application of which will much depend upon the care and painstaking with which they are carried out. Let me in conclusion urge everybody doing their best in such makeshift fashion to give serious attention to the value of annuals easily raised from seed in spring, affording a succession of the gayest loveliest flowers from spring till winter comes again, requiring no costly glass structures or puzzling makeshift contrivances, involving no outlay for fuel, mats, or straw, and yet when well cultivated are often more really ornamental and attractive than the most costly of our much-vaunted "bedders." Stocks, Asters, Zinnias, Phloxes, Petunias, Nemophilas, Saponaria, Senecio, Marigold, Poppy, Larkspurs, Balsams, and Portulacacas, all are worthy of a place—not one of them should be excluded, and all are perfectly within the means of an amateur.—EDWARD LUCKHURST.

HARDY APPLES.

By hardy Apples I mean those which appear to have hardy blossom or which are late in blossoming, and so escape injury from the frosts of an inclement spring. The spring of the present year was one of the most unpropitious that I have

Fig. 51.—Cellini.

experienced, and the Apple crop is consequently almost a complete failure. In your answers to correspondents you mention that Cellini has proved one of the most fruitful of Apples during the present year. I am able to confirm that statement. A few years ago I planted a considerable collection of Apples. Amongst them were three trees of Cellini, and so fruitful have these trees proved that I regret that I had not planted three dozen trees of an Apple so valuable. The three trees have produced more fruit than have a hundred other trees in the same collection. This Apple is as handsome and as good as it is prolific. I send a section of a fair-sized specimen and ask you to give the prominence to it which I consider it merits by figuring it, so as to impress it the more fully on the public mind as a serviceable Apple both for home use and for market purposes. It succeeds admirably on the Paradise stock, and makes a handsome bush or pyramid.

Another Apple deserving equally honourable mention is the old Court-Pendu-Plat: this is the latest-blossoming of all Apples, and I have never known it fail to set a full crop of fruit. As there is more than one variety cultivated under the same name, I ask you to engrave the section of the true old short-stalked variety as one of the most distinct, certain, and valuable of late dessert Apples.

Fig. 52.—Court-Pendu-Plat.

Other Apples which have proved exceptionally hardy during the present trying season are Cox's Orange Pippin, King of the Pippins, Stirling Castle, and Hawthornden.

I did not include Hawthornden in the list sent to Mr. Killick on account of its liability to canker on light soil; but on good soils it is extremely useful. I now ask Mr. Killick to place a double asterisk against the five sorts now named which are included in the list which I forwarded some months ago to Mount Pleasant, Langley, Maidstone.

This is the worst of all seasons for an Apple election, and I do not anticipate a large number of entries; still I hope if those who are able to do so will send lists to the address named of the best fifteen kitchen and fifteen dessert Apples valuable information will be forthcoming, especially if the sorts are marked which have best resisted the destructive frosts of the late inclement spring.—A NORTHERN GARDENER.

ROYAL HORTICULTURAL SOCIETY.

OCTOBER 2ND.

WE have to report an extensive, varied, and excellent meeting—one of the best that has been held for some time. Plants were not largely exhibited, but a collection of *Nepenthes* and insectivorous plants from Messrs. James Veitch & Sons afforded a rich treat by their great variety, singular forms, and excellent condition. Tuberous *Begonias*, Tree *Carnations*, double *Primulas*, bud blooms of *Roses*, *Dahlias*, and *Gladioli* contributed brightness to the Council-room. Fruit was also exhibited in superior condition, notably *Grapes* and *Pine Apples*, while *Cucumbers*, *Potatoes*, *Cauliflowers*, and *Watercress* in pans were well represented amongst vegetables.

FRUIT COMMITTEE.—Henry Webb, Esq., Vice-President, in the chair. Three splendid Smooth-leaved *Cayenne Pine Apples*, weighing respectively 9½, 9½, and 9½ lbs., were sent from Her Majesty's Gardens, Frogmore, and the Committee recommended that a silver Banksian medal be awarded to Mr. Jones the gardener. Mr. R. Hutton, The Gardens, Crown House, Southampton, sent two fairly grown *Providence Pines* under the name of *Charlotte Rothschild*; a vote of thanks was awarded. A cultural commendation was awarded to Mr. Jones, Bentley Priory, Stanmore, for a very good *Charlotte Rothschild Pine*, weighing 8½ lbs., from a plant not eleven months old.

A very fine collection of eight sorts of *Grapes* was sent from Messrs. Lane & Sons, Great Berkhamsted, Herts. It comprised fine examples of *Muscat Hamburg*, *Black Hamburg*, *Muscat of Alexandria*, *Gros Colman*, *Golden Queen*, *Mrs. Pince*, *Alicants*, and *Trebbiano*. The Committee unanimously recommended that a silver-gilt medal be awarded for them. Mr. R. Gilbert, The Gardens, Burghley, Stamford, sent two very fine bunches of *Gros Colman* with immensely large berries; a bronze medal was voted for them. Mr. Harrison Weir, Weirleigh, Brechley, Kent, sent *Muscat Champion* and *Venn's Black Muscat Grapes*, grown without the aid of fire heat. The specimens of *Muscat Champion* were very fine indeed, and they were recommended to the Council for a medal. From the Society's garden, Chiswick, came very good examples of *Frankenthal Blanc*; the berries were similar to the black sort, and the flavour sweet and refreshing. Mr. Barron also sent a collection of *Peaches* from the open wall; the fruit was remark-

ably well grown. *Belle Imperiale* was handsome and well flavoured. *Desse Tardive* is also an excellent late sort, but was not so well flavoured. *Osprey* is a yellow-fleshed sort, but of indifferent flavour. Mr. J. Tranter, Upper Assenden, Henley-on-Thames, sent a seedling *Gooseberry*, the fruit almost black, but the flavour was quite gone.

Mr. C. Tyler, gardener to R. Gosling, Esq., Hassobury, Bishop Stortford, sent a green-fleshed *Melon* named *Exquisite*. It was very fine indeed, and the Committee asked to see it again when quite ripe. Mr. E. Bennett, The Nurseries, Rabley, Herts, sent a scarlet-fleshed *Melon*, a cross between *Little Heath* and *Read's Scarlet-flesh*. It is a fine-looking *Melon* and will be a good market variety. Mr. Allan, The Gardens, Gunton Park, sent a scarlet fleshed *Melon* named *Royal Ascot*, of fair flavour. Messrs. Carter & Co., 237 and 238, High Holborn, London, sent a new type of *Melon*, deeply ribbed and with long-shaped fruit. The flavour was very good, and the flesh scarlet. It is very promising. The Committee wished to see it again. The same firm sent a new *Capsicum* with fruit as large as a medium-sized *Mangold Wurtzel*, and of a very rich scarlet colour. It was named *Giant Emperor*. Besides this there was a large collection of other sorts, comprising *Yellow Tomato*, the *Large Bell* or *Bull Nose*, *Purple*, &c. The Committee voted a letter of thanks and a cultural commendation.

A dish of *Garibaldi Strawberry* was sent by Mr. E. Bennett, and a dish of *Vicomtesse Héricart de Thury* from Mr. Allen; both dishes received a cultural commendation, and in all respects they appeared identical. A seedling *Apple*, *Lord Home*, was sent from Messrs. Harrison of Leicester; it is a kitchen sort of no apparent merit. Mr. Louis Killick, Mount Pleasant, Maidstone, sent examples of a kitchen *Apple* named *Stone Apple*. The fruit is of large size, and well merited the first-class certificate awarded to it. A dish of *Swanley Pippin* was sent from Mr. H. Cannell of Swanley, but it was not thought worthy of an award. Mr. Howle, Eleanor Road, Waltham, sent a dessert *Apple* named *Howle's Seedling*, but it was not thought an improvement on established sorts.

Mr. J. Lovey, gardener to G. Dixon, Esq., Gothenburg, Sweden, sent a very fine collection of *Pears* which had been grown in pots under glass. The fruit was very fine indeed, and equal to the best *Jersey Pears*. The collection comprised thirty varieties of all the most approved English varieties; also a collection of *Apples* splendidly grown, and two dishes of *Grapes*. The Committee unanimously agreed in recommending the collections for a gold medal. One hundred varieties of *Apples* were sent from the nurseries of Messrs. W. Paul & Son, Waltham Cross, comprising the usual well-grown examples for which this firm is noted. A letter of thanks was voted, and a bronze medal was recommended to be given for the collection.

A seedling *Onion* resembling *Bedfordshire Champion* was sent by Mr. Allen, but was not considered to be sufficiently distinct. A basket of very fine *Brussels Sprouts* was sent by Mr. Gilbert, but the Committee expressed a wish to see the sprouts as grown on the stem. Mr. C. Turner, The Royal Nurseries, Slough, sent a new white kidney *Potato* named *Early Bird*. The tubers were very clear on the skin, and remarkably handsome in shape, but it is a rule not to certificate *Potatoes* as shown in small dishes; it was therefore voted to be sent to Chiswick. A collection of *Cucumbers* was sent by Messrs. Kelway of Langport, but none of them were in condition. Mr. Miles, gardener to Lord Carington, Wycombe Abbey, exhibited ripe and well-coloured *Black Hamburg Grapes* from the same Vines from which ripe fruit was cut and exhibited in January of the present year. Col. Trevor Clarke exhibited a seedling *Grape* resembling the *Black Hamburg*; and a collection of upwards of forty varieties of *Nuts* was sent from the Society's Gardens at Chiswick.

FLORAL COMMITTEE.—G. F. Wilson, Esq., F.R.S., in the chair. Messrs. Veitch's grand collection of *Nepenthes* and insectivorous plants first merits notice. It was composed of about twenty species and varieties of *Nepenthes*, besides a remarkable display of *Darlingtonias*, *Sarracenias*, *Droseras*, *Cephalotes*, &c. Among the *Nepenthes* were admirably grown specimens of *N. Hookeri*, *N. Rafflesiana*, and *N. Cheloni*, with smaller plants of the *Chelsea* hybrids and some rare species. First-class certificates were unanimously awarded to three new varieties—namely, *N. hybrida maculata elongata*, its splendid long dark pitchers being very striking; *N. Courtii*, distinct and extremely fine; *N. rubra maculata*, dwarf, sturdy, free, and richly marked. We noticed also *N. intermedia*, very rich; *N. zeylanica rubra* from Ceylon; *N. Kennedyana* from North Australia, and the small but distinct *N. albo-marginata*. Amongst the *Sarracenias* *S. Cheloni*, the result of a cross between *S. rubra* and *S. purpurea*, was extremely rich and distinct. This valuable and unique collection was recommended for a gold medal, a distinction that it fully merited, for novelty was combined with rarity and grotesque beauty, and skilful cultivation was stamped on every plant.

Mr. Turner, The Royal Nurseries, Slough, exhibited winter-flowering *Carnations* in 5 and 6-inch pots. Too much praise

cannot be given to these plants for conservatory decoration, they are both beautiful and sweet. A first-class certificate was awarded to Osman Pasha, vermillion scarlet, smooth, and extra fine. The other varieties were Rose Perfection, Red Dragon, Mazeppa, Miss Joliffe, and Sir Garnet Wolseley. A vote of thanks was awarded. Mr. Turner also exhibited a splendid collection of Pompon Dahlias in upwards of fifty varieties. A glass stand in three tiers was also arranged with these miniature Dahlias and Ferns, showing how admirably they are adapted for that purpose of decoration. A vote of thanks was awarded for this arrangement. These early, free-flowering, and attractive Dahlias are not sufficiently grown in gardens. The collection was highly commended by the Committee. Messrs. Rawlings, Brothers, Romford, received first-class certificates for show Dahlias James Willing, crimson maroon, rich, and of excellent form; and Mrs. Shirley Hibberd, creamy white, faintly tipped with rosy purple, also of good form.

Messrs. William Paul & Son, Waltham Cross, Herts, exhibited an admirable collection of Roses in nearly a hundred varieties, including the new Rose May Quennell, very fine, and was awarded a vote of thanks.

Mr. Gilbert, Burghley Gardens, Stamford, exhibited four of his fine double Primulas, to three of which—Mrs. Barron, French white mottled with rose; Princess, pinkish white mottled and faintly striped with purple and white; Lady, fine pure white—first-class certificates were awarded. Lady Louisa, purplish crimson, was also very fine. These Primulas are remarkable for their fine flowers and the free and vigorous growth of the plants.

Messrs. Kelway & Sons, Langport, Somerset, exhibited a collection of Gladioli in varied colours and with the fulness of spike which characterises the best varieties of this renowned firm. A first-class certificate was awarded to Rhamnes, rich full scarlet with maroon bar and purplish rayed throat; very striking.

Mr. Roberts, gardener to Baron Rothschild, Gunnersbury Park, Acton, exhibited *Odontoglossum Rothschildi*, a richly spotted variety of *O. crispum*, distinct on account of the blue tint which suffused the flowers. A vote of thanks was awarded.

Messrs. Bell & Son, The Nurseries, Norwich, exhibited tuberos Begonias with bright flowers and the veined foliage of *B. Pearcei*; also a crested *Adiantum*—*A. Capillus-Veneris corymbiferum*. Messrs. Froebel & Co., Zurich, also sent tuberos Begonias. Mr. Cannell exhibited a compact plant of his Perfection French Marigold and bedding *Lobelia Defiance*, reddish purple in colour and very promising. Mr. Noble, Bagshot, submitted trusses of his new Rose Queen of Bedders, very rich and floriferous. Mr. Woollett, nurseryman, Caterham, sent *Cupressus Lawsoniana plumosa argentea*; Messrs. Stewart and Sons, Dundee, a purple-leaved Norway Maple. Mr. G. F. Wilson exhibited sprays of *Escallonia Pterocladon*, a white-flowered species, very attractive; Mr. Green, gardener to Sir G. Macleay, Pendell Court, Bletchingley, sent a plant of *Eryngium serra*; and from the gardens of Viscount Bridport, Cricket St. Thomas, Somerset, was sent the stem of an *Heliotropium peruvianum*. The plant was planted in 1837, and covered 700 square feet of the conservatory wall. The stem was about 4 inches in diameter and covered with rough bark. The meeting was largely attended by horticulturists.

INTERNATIONAL POTATO SHOW,

ROYAL AQUARIUM, WESTMINSTER, OCTOBER 3RD, 4TH, AND 5TH.

In extent the Show is perhaps not equal to the Exhibition of last year. The collections are arranged in the south and end galleries of the building, but the space is too limited for such a large exhibition being inspected with comfort. In quality—that is, uniformity of size of the tubers, and that size generally acceptable for table purposes, and for excellent shape, we unhesitatingly pronounce the Show a great advance on previous displays: it is, in fact, the best Exhibition of Potatoes that has probably ever been arranged. A few coarse tubers there undoubtedly are, and others not clear in the skin, but they are much less numerous than on former occasions. The Show opened in a dense London fog; the arrangements also appeared to be a little "foggy," for they were not completed for some hours after the appointed time. Time only permits our giving the awards and the names of the first-prize varieties.

The first class in the schedule is a somewhat imposing one, the prizes given by the Royal Aquarium Company being £12 12s., £8 8s., £5 5s., £3 3s., and £2 2s. for twenty-four varieties of Potatoes, nine tubers of each. There are thirteen competitors, the awards going as follows:—First to Mr. Peter McKinlay, Woodbine House, Beckenham; second to Mr. W. Finlay, gardener to Col. North, Banbury; third to Mr. Pink, gardener to Lord Soude, Faversham; fourth to Mr. Ironside, Keith Hall, Inverurie; and fifth to Mr. R. Dean, Ealing. Mr. McKinlay's splendid collection consists of Porter's Excelsior, Onwards, King of Potatoes, Climax, Brownell's Superior, Breadfruit, Purple Ashleaf, Early King, Grampian, Early Rose, International Kidney, Schoolmaster, Model, Salmon Kidney, Rector of Wood-

stock, Blanchard, Taylor's Seedling, Garibaldi, Alexandra Kidney, Late Rose, Snowflake, Emperor, Ashtop Fluke, and last but not least, a fine new kidney named Royal Aquarium.

In the next class Messrs. Sutton & Sons, Reading, provide a silver cup value £10 10s. as the first prize for eighteen varieties, nine tubers of each, open to gentlemen's gardeners and amateurs only. The second prize of £6 6s. is given by Mr. John Coutte, James Street, Covent Garden, and the third prize of £4 4s. by Mr. James Crute, Watling Street, London. Eighteen collections are staged, the awards being as follows:—First to Mr. W. Porter, King Street, Old Meldrum; second to Mr. Donaldson, Inverurie, Aberdeenshire; third to Mr. G. Bagerley, Syerstone Lodge, Newark; fourth to Mr. James Pink, Faversham. The cup collection contains splendid dishes of kidneys Bountiful, Improved Ashtop, Fluke Crimson Walnutleaf, International Kidney, Napoleon, Snowflake, Meldrum Conqueror, Blue Ashleaf, Albion Kidney; and of rounds—Blanchard, Rector of Woodstock, Grampian, Climax, Early Emperor, Blue Prince, Bresee's Prolific, and Porter's Excelsior.

Messrs. James Carter & Co., High Holborn, give all the prizes in the class for twelve varieties. The first prize of £6 6s. is secured by Mr. James Pink; the second, third, and fourth prizes going respectively to Mr. Charles Ross, gardener to C. Eyre, Esq., Newbury; Mr. William Finlay, gardener to Col. North, Banbury; and Mr. C. C. Cornfoot, gardener to J. Tassell, Esq., Faversham. There are seventeen competitors. The first-prize collection contains handsome dishes of Berkshire Kidney, Garibaldi, Snowflake, Bresee's Prolific, Early Rose, Coldstream, Waterloo Kidney, Red Emperor, Ruby, Birmingham Prizetaker, Early Goodrich, and Schoolmaster.

The Lawson Seed Company, Edinburgh and London, provide the first prize of £6 6s. in the class for nine varieties, which is won by Mr. R. Dean, Ealing, the remaining prizes going to Mr. Peter McKinlay; Mr. Ellington, Mildenhall, Soham; and Messrs. Lott & Hart, Whitehill Nursery, Faversham, in the order of their names. Mr. Dean's collection contains Climax, Blanchard, Salmon Kidney, International Kidney, Excelsior Kidney, Grampian, Extra Early Vermont, Purple Ashleaf, and King of the Potatoes, all of great excellence. Eighteen competitors.

The first prize in the class for six dishes is a silver cup value £5 5s., provided by Messrs. Daniells Brothers, Norwich. It is won by Mr. W. Finlay, Banbury. The second prize, given by Mr. C. Quincey, Peterborough, is secured by Mr. Ellington; Mr. Ironside, Keith Hall, Inverurie, being placed third; and Mr. Miller, Newbury, fourth. The winning dishes are extremely fine. They comprise Snowflake, Scotch Blue, Edgcott Seedling, Blanchard, Magnum Bonum, and Walnut Kidney; a fine class of twenty-three competitors. Mr. Pink's collection is highly commended; and Mr. Jones, Broughton House, Mr. Osman, Sutton, Surrey, and Mr. Gilbert, Burghley, are commended in this class.

Messrs. Wheeler & Sons, Gloucester, provide the first prize of £3 3s. in the class for four dishes, two of round and two of kidney varieties; and Mr. Cockburn, Falkirk, the second prize. There are twenty-three competitors, the awards going as follows:—First Mr. F. Miller, gardener to J. F. Friend, Esq., Margate; second Mr. J. Denyer, Penge Road, Beckenham; third Mr. George Donaldson, Inverurie, Aberdeenshire; fourth Messrs. Lott & Hart, Faversham. The first-prize collection consists of Ashtop Fluke, Breadfruit, Blanchard, and Snowflake.

In the class for four dishes, distinct, new varieties not in commerce, or in commerce for the first time this year, all the prizes are provided by Messrs. Hooper & Co., Covent Garden. There are twelve competitors, the first prize being won by Mr. James Pink with Superior, a fine red variety; Handsworth Superior, Seedling No. 2, and Covent Garden Perfection; second Mr. R. Dean with International Kidney, Radstock Beauty, Bedford Prolific, and Garibaldi; third Messrs. Lott and Hart. No name was attached to the fourth-prize collection, which consists of very fine examples of Ice Cream, Centennial, Telescope, and Heather-bell.

Messrs. Charles Lee & Son, Hammermith, provide the prizes in the class for two dishes, one round and one kidney. There are twenty-six competitors. Mr. R. Dean is placed first with International and Schoolmaster, very fine indeed; Mr. Miller second, and Mr. W. Howerd, Bridge, Canterbury, third; and Mr. R. Farquhar fourth; all exhibiting well.

All the prizes for the best dish of any white round Potato are given by Messrs. Harrison & Sons, Leicester. There are twenty-three competitors, the prizes being awarded in the following order. First, Mr. Robert Ironside, Ingleston, Inverurie, N.B., with Rector of Woodstock; second, Mr. Pink with Early Goodrich; third, Mr. J. B. Hall with the same variety.

Mr. B. S. Williams, Holloway, provides the prizes in the class for the best dish of any coloured round Potato, and they are awarded in the following order—first to Mr. Pink with Red Emperor, second to Mr. R. Dean with Radstock Beauty, and third to Messrs. Lott & Hart. Twenty-eight competitors.

In the class for the best dish of any white kidney Potato the

prizes are provided by Mr. Charles Turner, Slough, and are won—first by Mr. Miller with Yorkshire Hero, second Mr. W. Finlay with Lapstone Kidney, third Mr. Thos. Wraight, gardener to Major Curtess, Rye, Sussex, with Jackson's Kidney. Twenty-one competitors.

Messrs. James Cutbush & Son, Highgate, give the prizes in the class for the best dish of any coloured kidney variety. There are twenty-one competitors, with the following result:—First, Mr. J. S. Evenden, Longfield, Dartford, with Superior; second, Messrs. Virgo & Son, nurserymen, Guildford, with Early Vermont; third, Mr. James Pink, also with Early Vermont.

In the class for the best dish of Snowflake the prizes are given by Messrs. Edward Webb & Sons, Wordsley, Stourbridge. The awards are—first, Mr. Pink; second, Messrs. Bliss & Sons; third, Mr. R. Farquhar, gardener to Col. W. C. Gordon of Fyvie. Twenty-one competitors.

Mr. J. Cattell, Westerham, provides prizes for the best dish of Ruby Potato, which are won as follows:—First, Mr. Chas. Ross, gardener to C. Eyre, Esq., Newbury; second, Messrs. Lott & Hart; third, Mr. Pink. There are ten competitors.

For the best dish of Porter's Excelsior the prizes are given by Messrs. Thomas Gibbs & Sons, Down Street, Piccadilly. The successful competitors are—first, Mr. Pink; second, Mr. Ross; third, Mr. John Belliss, gardener to Major Thoyts, Reading. Nine exhibitors.

The last class in the schedule is for the best dish of Schoolmaster, the prizes being given by Messrs. Barr & Sugden, 12, King Street, Covent Garden. There are eight competitors, with the following result:—First, Mr. J. B. Hall, Gillingham, Kent; second, Mr. E. Bennett, Enville, Stourbridge; third, Mr. T. Worsfold, Horsham.

The varieties named in the four last classes are for some reason or other excluded from competing in the other classes for single dishes.

In the Miscellaneous classes Messrs. Sutton & Sons, Reading, exhibit a fine collection of Magnum Bonum; Messrs. James Carter an imposing stand of 180 varieties, including some superior produce from Sandringham; Mr. Turner, Slough, splendid examples of Schoolmaster; and Messrs. Daniels, Bros., Norwich, a sensational stand containing five hundred named varieties. Mr. Porter, Old Meldrum, also stages a fine miscellaneous collection. Messrs. Kelway exhibit Gladioli, and Mr. Turner Pompon Dahlias. The Exhibition, which continues until Friday evening, is highly worthy of extensive patronage.

NOTES AND GLEANINGS.

A FULHAM CORRESPONDENT writes:—"On the morning of the 25th ult. we had a foretaste of winter; the thermometer registered 6° of frost, and the gardens about here presented the aspect of Christmas. We have recently had dense fogs until about midday. Crops are beginning to show symptoms of drought—for instance, Savoy, Spinach, and other green crops are suffering for want of rain."

It may be interesting to some of your readers to know that quite one-half of the enormous crop of Tomatoes in the market gardens about Fulham were destroyed by the disease, which seems to be becoming an annual occurrence. But with this loss the firm of Messrs. Bagley have been sending to the market one thousand baskets of Tomatoes per week, three baskets being equivalent to a bushel. The plants are grown in the open fields and are trained to short stakes.

A CORRESPONDENT, "G. C.," states that for the last three years he has washed his Potatoes at the time of taking them up, as he can then pick out the bad tubers much better. When the sound tubers are thoroughly dry he stores them away, and has not found 1 per cent. go bad afterwards. The kinds grown are Haigh's Kidney, Mona's Pride, and Paterson's Victoria.

We have received from Mr. Joseph Bentley, Lincoln, heads of VEITCH'S AUTUMN GIANT CAULIFLOWER. They are admirable examples of culture of one of the most valuable of autumn vegetables.

WATERCRESSES.—At the meeting of the Royal Horticultural Society on Tuesday Mr. Shirley Hibberd of Stoke Newington exhibited a dozen pans of Watercresses, grown in the manner he has practised and recommended for some years past. One of the advantages of this system is that the plants are under complete control to be placed in the sun or the shade, or during winter in heated plant houses, and can at all times be supplied with pure water, and thus be preserved from contamination by the pollutions common to rivers, brooks, and even Watercress beds. The pans in which the Cress is grown measure from 15 to 20 inches across, and from 6 to 9 inches deep. The pans are filled with rich loamy soil intermixed with lumps of chalk or old mortar, and then very small

cuttings are inserted. These soon become strong plants, and in from fifteen to twenty days they may be gathered from, the produce being tender and delicate in flavour, and of the most beautiful appearance. The twelve pans shown have been regularly gathered from for the table for a period of six weeks, and their fresh and robust appearance indicated that they might be cut from for another six weeks without being exhausted.

ONE of the most attractive and elegant of variegated plants of easy culture is *HEMEROCALLIS FLAVA VARIEGATA*. We recently observed it at the Crystal Palace, where Mr. Thomson had it in excellent condition and regarded it favourably as a table and general decorative plant. Its leaves are clearly striped and arch in a pleasing manner. It was growing in a warm greenhouse, and the temperature appeared to suit it admirably.

In the south of Devon the BEECH TREES are loaded down to the ground with nuts. I never saw such a bearing before. The trees have an elegant appearance, and the squirrels have a fine time of it, for not only the Beech-nuts but the Hazel-nuts are abundant; but acorns are very scarce.—SOUTH DEVON.

MR. HARDING, gardener to the Rev. W. Arthur, Clapham Common, has, we are informed, been appointed to the charge of the Dowager Marchioness of Huntley's garden at Orton Langueville. Mr. Harding is known as a successful exhibitor of Chrysanthemums and vegetables at the Royal Horticultural Society and other metropolitan shows, and he is an occasional contributor to the columns of this Journal.

NOTES FROM CORNISH GARDENS.

TREGOTHNAN, THE SEAT OF VISCOUNT FALMOUTH.

"DOWN a shady vale" passes the road by which I went to Tregothnan. Lofty trees shut it in and overhang it; not those awe-inspiring "monarchs of the forest" which we admire—almost worship, but a motley crowd of wildings with just enough fine trees among them to show that neither soil, climate, nor trees are at fault, but that man's fostering care is wanting; not that we should like to see an ardent improver let loose upon the woods, for the trees are so lofty and so old that sound judgment, practical skill, and an artistic eye are now more requisite for their treatment than when they were younger. They afford proof that a judicious clearance of weakly growth is a fundamental rule of forestry to which due weight is not given, although it is fraught with such momentous consequences. Why do I dwell upon this wooded valley, and not hasten at once to the gardens to which it leads? Because it is literally a garden itself—just one vast fernery, such as I had never seen before. On all sides—from the road down to the margin of the stream, away up the steep and undulating slopes far as the eye can reach among the soft light of Nature's arcades—there are thousands of Ferns, most of them magnificent specimens of elegant form and extraordinary size, for they are not all crowded together in one continuous mass, but are dispersed in clumps and singly in a wild but charming manner, sometimes clothing an entire slope with their charming frondage, and frequently, much more so than is usual, standing out alone on little hillocks and promontories, showing their large size and graceful proportions in a way as striking as it is singular and pleasing. I had no idea that Scolopendriums would grow to such a size as I saw them here by hundreds. The plants were doubtless very old, each having some dozens of glossy green fronds—long, broad, and recurved—springing from the crown in circles, drooping gracefully outwards tier above tier, forming such large bold tufts as to worthily rival the grand old specimens of *Laetrea Filix-mas*, the *Polystichums*, and *Osmundas* with which they are intermingled. Right up the stems of many of the trees and along the branches 50 or 60 feet from the ground *Polypodium vulgare* was growing in perfect health, imparting to the trees an odd sort of Jack-in-the-green appearance, more curious than beautiful.

Well, my walk from Lamorran to the gardens of Tregothnan was among those wonderful Ferns for the greater part of the way; it was therefore a pleasant walk, and when I reached the gardens another extraordinary sight awaited me at the very entrance—an avenue of Camellias, or rather a double row of them standing out upon the turf on each side of the path which swept onwards into the interior of the shrubbery. Every plant was a perfect specimen—globular in outline with the foliage large, green, glistening with health, and so dense as to conceal every trace of branch and stem. I have applied

the common term of plant to them, but it is inappropriate, for they are veritable shrubs 4 or 5 feet high and as much in diameter. So perfect in every point are they that one hesitates to criticise, but duty compels me to say that the arrangement is a mistake; the formal aspect of such long lines robs the scene of that grace which it ought to possess, and which might be so easily imparted to it by throwing the Camellias into clumps—some standing out in large circles upon the turf, others spreading backwards in long flowing curves to meet and blend with the shrub borders behind. The scene would then be magnificent and unique, few if any gardens in this country containing such a number of Camellias growing in the open air.

Beyond the rows of Camellias the lawn opens out into a bold ascending semicircular expanse on one hand and downwards over slopes on the other. Numerous shrubs and trees fringe the boundaries and stand out upon the turf. Many of them

are excellent specimens, notably some Camellias arranged with the happiest effect in a bold group upon the semicircular lawn. Here too are Rhododendrons, many of them seedlings of arboreum and other species raised by Mr. Boscawen, and bearing the impress of his handiwork in the large foliage and vigorous growth peculiar to all the Lamorran seedlings. Some dwarf Fan Palms planted out here are in excellent health, and are evidently making steady progress upwards. One day they will no doubt be regarded as a feature of prime importance. They are worthy of all care, and it is matter for regret that the largest of them all—a really fine *Chamærops Fortunei*—is almost lost to view in an odd angular nook, which might easily be opened out and converted into a semicircle. A much more prominent position has been given to a remarkable specimen of what I believe to be *Acacia dealbata*, nearly 30 feet high. In making this statement I am well aware that

Fig. 23.—TREBOTHNAN.

exception will probably be taken to it; there, however, stands the tree—an undoubted *Acacia*, and my attention was called to it as a fine example of the Green Wattle *Mimosa*—*A. affinis*. Whether it may ever be proved to be another variety is not, I think, so important as the actual fact of an Antipodean *Acacia* having attained to such proportions in the open air.

Many varieties of Conifers planted near this lawn with choice deciduous trees have thriven, but the growth is becoming sadly crowded. Another evil that is telling upon some of the best specimens is a want of adequate shelter, the growth being perfectly healthy till it gets above the surrounding trees and then it dies—killed by cold winds, and, of course, the tree is spoilt. *Picea Nordmanniana*, still unscathed, is very handsome; *Picea Webbiana* is not healthy, and is bearing cones freely; *Pinus pseudo-strobus*, with pendant clusters of very long foliage, is distinct and striking; it is worthy of culture wherever it will grow as it does here, but unfortunately it is rather tender, which accounts for it being so seldom seen. A *Pinus Montezumæ* exhibited in a striking degree the effects of frequent removal in its stunted, weakly, shrub-like growth. When a tree of 12 feet and upwards is transplanted it requires four or five years before it is thoroughly established in its new quarters, repeated liftings affecting it so much as to gradually change its character from a fast-growing timber tree to a stunted shrubby nondescript, hence the importance of care and sound

judgment in the selection of the permanent position of a tree and in planting it there when quite young.

A walk winding among shrubs leads upwards and onwards to one of the most important features of the gardens—an extensive lawn on a gentle slope with enclosing belts of shrubs, which sweep downwards from a broad walk at the top in bold curves, gradually converging till they meet and blend with other shrubs, clothing the side of a valley which this lawn commands. The broad walk along the top is a quarter of a mile in length in a straight line, having a seat of massive slabs of granite at one end, and at the other a piece of statuary, very ineffective when viewed from the seat, and which might advantageously be replaced by an obelisk or a group of statuary bolder and more massive in character. Midway and slightly back from the walk stands a rustic cottage overlooking the whole of the lawn and the valley down to which it trends. The valley forms a charming vista, stretching away for a considerable distance with wooded slopes rising in the form of an irregular semicircle at its lower extremity; its only blemish a clump of timber stretching across the valley, spoiling the grace of its flowing lines, and causing one to turn with regret from the contemplation of a scene that but for it would be most beautiful. It was a happy thought which prompted the artist to put no shrub groups on this lawn, the wide unbroken expanse of turf imparting a dignified aspect that is eminently

in keeping with its commanding position, with which also the noble promenade along the top is in perfect harmony. It is a masterly conception well wrought out, worthy of unqualified praise and admiration.—EDWARD LUCKHURST.

(To be continued.)

THE GRAPE SPOT.

JUDGING from the many answers to correspondents on the subject of Grapes spotting and scalding which appear in the Journal from time to time, it is pretty plain that if the secret of prevention of the injury is found out and turned to account by some cultivators, there are still a goodly number who seem to be in the dark as to how to deal with it. The cause of the spot may probably be traced to more than one source; at the same time I am thoroughly convinced that a sudden change of temperature is the main cause. Some Grape growers advise a high temperature with dry atmosphere, while others prefer a low or medium temperature with a little moisture.

I know no varieties so subject to spot as Madresfield Court and Lady Downe's, especially the latter. I have had a good deal to do with this variety, and my experience is that much depends on the state and condition of the Vines. The Vines being in perfect health, I would advise the following treatment: As soon as the buds begin swelling provide a little fire heat, keeping the house moist till the Grapes are in flower; then increase the heat and lessen the moisture, admitting air as required, always leaving the top ventilators slightly open. As the berries approach the critical or stoning period endeavour to maintain an equilibrium of heat and moisture, for I am an advocate of both. If the mornings are bright admit more air as soon as the sun strikes theinery, continuing to increase the ventilation till near noon. Damp twice before noon and once after. If we happen to have a bright spell of weather just when stoning is going on mix some lime putty with water, and with this syringe the glass outside; it breaks the scorching rays of the sun, and at the same time does not make the house too dark. Still all this trouble will not insure success if all else is not right. An overcrop on delicate Vines is a great and rather a common danger: on such Vines the berries will spot in spite of all we can do. I know of two houses of Lady Downe's. The Vines in one house have a very light crop on them, and yet have many spotted berries although they have received careful treatment, while the Vines in the other house have an extra heavy crop with little or none of the berries spotted. My theory is that the lightly cropped Vines, although to all appearance healthy and strong, have not the sound constitutional qualities essential to fruitfulness, while the more heavily fruited Vines have by their real health and vigour not only been able to bear a good crop, but have been able to cope with the spot under the good treatment which I believe they received; and I observed that what few spotted berries were on the Vines were all on the rods bearing the heaviest crop, and scarcely any on a rod which carried a light one.

I believe I have seen it somewhere stated that the cause of spot is the sun's rays coming in direct contact with the berries. This theory will not stand, for I have often observed that bunches entirely shaded by leaves were sometimes quite as much spotted as those exposed to the sun, and my neighbour, a nobleman's gardener, has pointed the same fact out to me on Vines under his charge. A proper equilibrium of heat and moisture, I suggest, is the best preventive of the spot. The subject is worthy of notice, and I hope to hear more about it from those who have been taught in the school of experience.—B. G., Co. Down.

FLORAL CONCERT DECORATIONS.

THE promenade floral concerts which were inaugurated a month ago at the Agricultural Hall, Islington, appear to have been very popular. It will be remembered that large prizes were offered and were won chiefly by Mr. Wills and Mr. B. S. Williams. At the expiration of the period of the exhibition—a week—the two floral decorators were engaged to embellish the Hall for a longer period. They have done their work well, and have sustained a really extensive and artistic exhibition for the period of a month. It is estimated that sixteen thousand visitors were present at the last concert, when it was noticeable that the visitors appeared to derive as much pleasure by inspecting the flowers as by listening to the music. An

avenue of fine standard and pyramid Bays was formed in the covered approach to the Hall. In the auditorium tall specimen Cordylines were placed at wide intervals, and the margin of the promenade was rendered attractive by valuable ornamental-foliaged plants and flowers; large raised flower beds were also formed in various parts of the Hall. The flowering plants employed were chiefly Lilliums, Tritomas, and Gladioluses. The plants which have endured their long sojourn with the least injury are Palms. Crotons have suffered somewhat, as have some of the Tree Ferns, although *Dicksonia antarctica* and *Cyathea medullaris* appear about as fresh as ever. The general condition of the plants, however, denotes that they have not only received good attention, but that the Hall is well adapted for displays of this nature. Amongst the decorations were examples of artificial rockeries and rustic work. The

Fig. 54.—Artificial Rockery.

accompanying figure represents the exhibit of Messrs. Dick Radclyffe & Co., which was awarded the first prize in this section of the decorations. Mr. Wilson, ex Crystal Palace, remained "on duty" throughout the period, and is now engaged on a show of another nature—dairy produce and poultry.

CEMENT WALKS AND EDGINGS.

SOME three years ago when I took charge of these gardens it became necessary to entirely remodel them. We commenced first with the kitchen garden, which was to be solely confined to fruit and vegetables—no flowers were to be permitted in it. There was one especial subject I was to try to effect something original in, and that was the edgings of the walks, the old favourites Box, Thrift, Grass, Gentians, &c., and also the fancy earthenware edgings, not meeting my employer's wishes. I therefore proposed plain cement edgings; and then the idea struck me, Why not have cement walks too? Having received my employer's sanction to this, and after three years' experience of them, I wish to state briefly my opinion of these walks.

Firstly, they are a great saving of labour throughout the year; secondly, they always have a clean and neat appearance; thirdly, when once made they require no repairing, no keeping up, and therefore the first cost is the only expense; fourthly, where a quantity of heavy wheeling is done it is done much easier, as half the propelling power is not required on them that is necessary on ordinary gravel walks. The only attention these walks require is the sweeping of them. For this purpose we use a fine hair brush, as it removes all the dust from them. When any adhesive dirt gets on them, which sometimes happens after a quantity of wheeling, all that is required is to apply a bucket of water and a hard whalebone brush, and it soon all comes off; in fact even that much trouble is scarcely

ever required, as the first subsequent shower invariably cleans the walks sufficiently.

The garden here is oblong in form with a walk through the centre, and the other walks running parallel on the north and south sides respectively. Pyramid Apples and Pears are planted on both sides of the central walk; each tree corresponds in height and form as nearly as possible with its opposite neighbour, and behind the rows of trees and the walk there are two rows of Strawberries planted, and the dark green foliage of the Strawberries contrasts effectively with the white appearance of the cement. When this avenue of trees is in bloom in the month of May the effect is very pleasing; but perhaps there is no time these walks have a more striking effect than during moonlight, they are certainly most picturesque then. Some of the walks have marginal rows of Beet and Parsley. These walks make a pleasant promenade which can be used at all times; it matters not how wet it may have been, so long as it is dry overhead. They will scarcely damp the sole of any lady or gentleman's dress boot—in fact water perfectly passes off them, and there are openings scarcely visible left at the sides of the walks near the edge, where the water makes a quick exit.

Now as regards their making, it is quite simple: 8 inches of excavation will do, then the cement edging is laid. About 4 inches of rubble does for a foundation. Anything will do for this, either broken stones or bricks, and act well. We use clinkers from the colliery, which is close at hand. On this the cement is laid, which is composed of Portland cement and ground bricks mixed together. The workman fashions it into the shape required, and just before it dries he shakes pure cement on, which gives that charming white appearance so highly prizeable here. The cement is spread in blocks of 8 feet long, and every alternate one is done first, so as to allow of expansion in setting. In winter weather the walks are apt in very severe weather to become slippery; we then use silver sand and salt and keep the walk well swept, and we then experience little if any inconvenience on that account.

The walks were laid by Messrs. W. B. Wilkinson & Co., Newcastle, at a cost of 3s. 6d. per square yard for the walk and 1s. 9d. per lineal yard for the edging. This perhaps to some may be considered expensive, but it is the first and last cost.

I may here mention that the gardens and the estate likewise are swarming with ants. When these walks were first made the ants perfectly covered them, so much so that we could have swept them up by shovelfuls, and so did worms after rain too.—B. COWAN, *Aswell Park Gardens, Blaydon-on-Tyne.*

IN THE NORTH.—No. 2.

ABNEY HALL, CHEADLE, THE RESIDENCE OF
SIR JAMES WATTS.

THE President of the Manchester Botanical Society has long been known for the energy with which he has entered into the pursuit of horticulture, and his residence (within about six miles of Manchester) has deservedly acquired a high renown for the excellence of its cultures and the careful manner in which it is kept. To those of us who live far from the busy haunts of men it sounds somewhat startling that it is only on the verge of the zone within which the Oak will thrive round a Cottonopolis. You meet with other trees in some degrees of luxuriant growth, but until you pass the boundary you meet with no Oaks of any degree of vigour. I saw none on my way here, and I am told it is the same on other sides of the city; but once within the gates of Abney Hall you may fancy yourself at any distance from the noise and bustle you have just left behind you. There is a diversified character in the grounds of which the most has been made, and a fine avenue of *Cupressus Lawsoniana* is a feature which you do not see in many places of much greater size, while specimens of other Conifers and other shrubs are scattered throughout the grounds.

An exhibitor Sir James Watts has made his mark; and although now he has withdrawn from the contest, you meet in going through the houses the plants which have won for him the distinction he has acquired. At the last Manchester Exhibition some of these plants occupied a conspicuous place, although he no longer enters the lists as a competitor. Here, for instance, are plants of *Genetyllis fuchsoides* and *tulipifera* some 4 feet through; then, again, there is a fine plant of *Boronia pinnata* quite as large. The Azaleas also were very fine; they were not fully trained but allowed partly to grow naturally, and the effect was exceedingly good. Then the Orchids were excellent, more especially the *Deadrobiums*; such sorts as

densiflorum, *Fraserii*, &c., being huge masses 3 to 4 feet through and as full of bloom as they could possibly be. Heathas, too, were exceedingly well done, some large specimens 3 to 4 feet in diameter exhibiting great skill in their treatment.

But after all the grand feature of the place is the conservatory, and of the conservatory the Camellias. The conservatory adjoins the mansion and is a well-designed and ornamental building, but once inside it all this is forgotten in the glorious specimens of the lovely flowers with which it is filled. Although I have seen a good many Camellia houses—notably do I recollect one many years ago at Lord Middleton's at Wollaton near Nottingham—yet I do not recollect anywhere to have seen grander or more healthy plants than those. They were planted out, and some of them could not have been less than 20 feet high. At the period of my visit they had long passed out of flower and were making rapid growth for next season, but when at their height of bloom the sight must have been grand. The sorts were nearly all of the best and most useful kinds grown, such as the old Double White, which still retains its position as the most useful of all the pure white kinds. Then there was *Fimbriata Alba*, a most lovely kind; *Imbricata*, of which there were two plants fully 20 feet high; *Countess of Derby*, *Contessa Lavinia Maggi*, *Cup of Beauty*, *Sarah Frost*, *Jubilee*, ever vigorous and free-blooming, and many others. Another house was also devoted to Camellias, which were brought in here to bloom, while the Orchids and other flowering plants added great gaiety and beauty to the house.

Of course under the care of so experienced a gardener as Mr. McKellar every department of the garden was in excellent order. Bedding plants were in immense quantities and in fine condition; Vines were healthy and full of fruit; the Peach house also afforded a remarkable contrast to the condition of trees on walls everywhere this untoward season. But it seems to be useless to expatiate on these, which are to be found in every well-ordered establishment. I have indicated what seem to me to be the chief features of the place and what make it well worth a visit. Sir James Watts himself is now unable to do as he was always ready to do, but his courtesy is the same as ever, and permission is readily accorded to view the grounds.—D., *Deal.*

GRAPES CRACKING.

ON page 230 "A KITCHEN GARDENER" informs us that he has succeeded this season in preventing the cracking of his Grapes by letting three or four of the laterals on the tops of the Vines grow at will. He does not inform us what sorts the Vines are. "A KITCHEN GARDENER" may be right and I may be wrong, but I do not feel satisfied that by allowing three or four of the laterals on the top of a Vine to grow and not pinch them will prevent the cracking of Grapes; or why should one sort crack more than another? Some Grapes never crack, while others grown under precisely the same circumstances always crack. Why is this?

Last year a writer in the Journal said that he had succeeded in preventing his Grapes cracking by denuding the Vines of some of their foliage. His practice was quite the opposite of "A KITCHEN GARDENER's," and yet both state they succeeded in preventing their Grapes cracking. "A KITCHEN GARDENER's" practice would certainly lessen the flow of sap into the berries, but the practice of your other correspondent would, according to my ideas, force more into them, and cause them to crack worse. This leads me to believe that it was not the means adopted by your correspondents that prevented their Grapes cracking.

About two years ago we potted a Vine of Madresfield Court to see if by growing it in a pot we could prevent it from cracking its berries. It grew well and ripened a good cane, which the following season showed fruit. One very fine-shaped bunch was allowed to remain, all the others being removed. It set its berries well, and all went as well as could be desired until the berries commenced colouring, when they as usual began to crack. On the first signs of cracking less water was given to the roots to lessen the flow of sap into the berries. To such an extent was the water withheld that the Vine would often flag. Still cracking went on until scarcely a sound berry was left. There was at the same time abundance of foliage on the Vine. Another instance: Last spring we planted out in the vinery a Vine of the same sort, which grew well and ripened a shoot to the top of the rafter. It was last winter cut-back to within 5 feet of the border. This spring it broke

well, and every bud showed several bunches, and as the Vine was very vigorous two bunches were left. This Vine has been allowed to grow with very little restriction, and has a thoroughly ripened shoot as thick as a man's thumb, with laterals in abundance. It set its berries well, and all went as before until the berries began to colour, then they began to crack. So soon as it was noticed that the berries were cracking, the shoots which bore the bunches were cut half through to try and prevent more berries going, still they went till the bunches were good for nothing. Why was this? If the restricting of the flow of sap prevents the berries cracking, why did it not do so in my case? Certainly everything was done to lessen the flow of sap into the berries, but it did not prevent them cracking. This leads me to believe that it was not the practice adopted by your correspondents that prevented their Grapes cracking, neither do I believe that anyone can be certain what causes Grapes to crack.—W. HARRIS.

WINDOW GARDENING.

THE possibilities of window gardening are various and great, much more various and far greater than those unaccustomed to close observation would imagine. Even within the circuit of the metropolis, smoke-begrimed and foggy though the atmosphere be, great things may be, indeed are, done—greater things indeed than are to be seen in any other town in England. This is in measure owing to the fact that the population of London is cosmopolitan, and immigrants from sunny Italy or buoyant France not unnaturally desire to surround themselves with as many mementos as possible of the flowery lands they have left. Strangely enough it is not among the mansions of the upper ten that the possibilities of window gardening are carried out to their utmost, although here and there we see an example of what might be done: such for instance is the area of a house in Grosvenor Square, where Geraniums, Fuchsias, Calceolarias, evergreens, Ferns, climbing plants, and even Palms are employed with such effect as to convert a few feet of paved yard into a pretty garden.

Middle-class dwellings have as a rule the best display of window gardens, here and there the arrangement being so novel and so artistic as to prove that they are the emanation of personal taste, not a slavish following of a too prevalent fashion. Nor do we find this only among the well-to-do. Here and there amid the very poorest class of dwellings in the suburbs, aye, even in the metropolis itself, there crops up a palpable outburst of that universal love of the beauties of nature which has been implanted in man by his Creator, and which, crushed down and repressed by the hard necessities of daily existence, never becomes wholly extinct.

In taking our walks abroad we have lately seen several noticeable features in window gardening, details of which we subjoin. A terrace house with an underground parlour, the front garden rising in a slope from the house, the first-floor room having a projecting bay-window: from the garden up to this window is a screen of octagon wire, over which are trained *Tropæolum canariense* and *Convolvulus major*. These two plants form a beautiful flowery screen to the window of the ground-floor sitting-room, and being annuals the apartment is again open to the light in winter. The restricted space of the front garden is laid out to the best advantage and with excellent taste, the ever-popular and brilliant colours of red, blue, and yellow of Geraniums, Lobelia, and Calceolaria being toned down by a judicious admixture of less showy subjects, the whole presenting a refreshing relief to the sight from the preponderance of good foliage and freshly green turf, forming a pleasant contrast to the generally glaring dusty appearance of the white-stone-fronted houses on this, the sunny side of the Grove Road, Hammersmith. Another novel and pretty arrangement of a miniature garden in the same neighbourhood is as follows: Along the railing against the road a healthy Virginia Creeper is trained, also over the dividing wall between this and the adjoining premises, and right up one side of the house and along the balcony of the lower windows, from which it hangs in light and graceful festoons. The green of the creeper and the beautiful smooth sward of the liliputian lawn form an excellent groundwork for the well-arranged bedding-out plants, which are of the usual order, the special feature of the garden consisting in the employment of the profuse-flowering rich deep purple hardy Clematis, for covering a series of low arches across the end of the garden nearest the windows of the house, the growth of the climber being so dense that the wire is completely hidden, and the flowers so

numerous and closely set together that the whole forms a striking mass of bloom. The introduction of some tall free-flowering orange-coloured Nasturtium would make the picture perfect.

These are gardens of the well-to-do, and to keep them up a certain if not very large amount of expenditure is necessary. A flat-fronted one-storeyed shop in a little back street off Hammersmith Broadway scarcely seems an eligible place for a garden, yet one has been made of such a spot. As before stated, the front of the house is perfectly flat, but above the shop-front a wooden stage has been hung; on this are placed as many Fuchsias and Geraniums, Calceolarias, &c., as can be crowded in a miscellaneous but no less pleasing collection. The plants are full of flower, and the blooms of the Fuchsias hanging in such clusters that stage and pots are both entirely masked. On either side of the stage are pots of blue Lobelia and Creeping Jenny. A string fastened below the rim of the pot and tied to a nail holds them in place; and this hanging garden is, it is almost needless to say, a delightful picture in a poor neighbourhood.

Before leaving the subject, the employment of virgin cork, now becoming so general for window decoration, deserves a word. No one can deny how readily and beautifully this substance lends itself to garden decoration, but it must be in suitable situations. The effect of its employment for facing window balconies to stuccoed or flat-brick houses is incongruous and inartistic in the extreme. For conservatories and picturesque country cottages it is invaluable. Those who would see how well it may be used under cover should pay a visit to the "Grotto," Villiers Street, Strand, where an entire ground floor has been converted into a perfect cavern of coolness and beauty, fresh green feathery Ferns and other plants growing freely from the fissures of the cork.—T. S. J.

FUCHSIA PROCUMBENS.

"This curious little plant," states the "Botanical Magazine," t. 6189, "so unlike a Fuchsia in habit and colour of the flower, was discovered in 1834 by Richard Cunningham in the northern island of New Zealand, on the shores of the east coast, opposite the Cavalbos Islands, growing on the sandy beach, where it has since been gathered by Colenso. It has also been found on the Great Barrier Island by Mr. Kirk in two localities both near the sea."

The above extract shows it to be a seaside plant, yet, like our Asparagus, it thrives wonderfully well inland without any application of saline matter beyond that found in turfy loam and leaf soil.

Its habit is prostrate or trailing, having small wiry stems, alternate small leaves bearing some resemblance to the Fuchsia, but very much smaller; its habit reminding of *Linaria Cymbalaria* rather than a Fuchsia, running along the ground scarcely an inch in height, covering it with a close carpet of green, though the young leaves have a reddish tint when young, also the stems, which latter change to reddish purple. It is about as much like a Fuchsia as *Ficus repens* is like a Fig or India-rubber Plant. Unlike *Ficus repens* and some other trailers, it does not emit, so far as I have noticed, roots at the joints; therefore it is not disposed to climb, but grows straight away. I had a few cuttings in spring—it being very readily increased that way—which grew so rapidly and hung down the sides of the pot so gracefully as to suggest, What an admirable basket plant it would make! We put three small plants in a basket, and suspended it about 8 feet from the floor. It grew so fast that in August depending all around were shoots and foliage 3 to 4 feet, and they would evidently have grown had it been allowed until they had reached the floor. Clearly it is a good addition to the very few really good basket plants we possess for the greenhouse.

The flowers are produced at the axils of the leaves, and unlike a Fuchsia, have the tubes upright—no drooping in this case, for if the shoots depend the flowers are reared directly upward, and very curious and pretty they are—green, yellow, and purple—having the form of a Fuchsia. The flowers of this Fuchsia being inconspicuous, it may be asked, What is there about the plant to recommend it? Well, the flowers are followed by berries, oblong or elliptical in shape, about an inch long and two-thirds that in diameter in the middle, which at first are greenish-yellow or whitish, changing to rosy-purple, which render the plant attractive. Eggs, indeed, they would be; and is it not stated in the "Gardener's Dictionary" (Johnson's), that "when gardeners discover the way to im-

prove the size and flavour of fruits we cannot doubt but that those of the *Fuchsia* . . . will be amongst the first novelties in the dessert?" Dr. Hogg, in "Vegetable Kingdom," page 358, says, "*Fuchsia exorticata*, a native of New Zealand, yields fruit which is pleasant, very sweet, and eaten with great avidity by birds." Is this species in cultivation?—G. ABBEY.

KITCHEN GARDEN CROPS IN THE SOUTH OF IRELAND.

WE have now come to the close of another active season, and perhaps a few notes relating to my experience may be acceptable to some of your numerous readers, especially to those who, like myself, have to contend with an extremely wet and cold climate. We have had an exceedingly unfavourable year, and I am sorry to say that in many cases the results were anything but satisfactory. The spring was hard and bitter, the summer cold and wet with a great deficiency of sun heat, so that excellence among many crops of the kitchen garden might be sought for in vain; however, I will give a few stray notes on those vegetables which in my experience best suit a damp soil and a heavy dripping climate.

PEAS.—Those which I find do best in our climate are as follow:—First sowings.—Dickson's First and Best, Carter's First Crop, Sangster's No. 1, and Laxton's Prolific; these, when sown at the same time form a good succession. For second sowings Laxton's Prolific, Laxton's Supreme, and McLean's Little Gem; these also follow in well. Third and general sowings.—Ne Plus Ultra, Williams's Emperor of Marrows which is a splendid Pea, Veitch's Perfection, British Queen, Hundredfold, and Hair's Dwarf Marrow. Fourth and last sowings.—British Queen, Champion of England, and Laxton's Omega. Those, if sown as described and at proper intervals, give a long and plentiful supply, coming in well in succession from the 20th of May till the middle of October. Everything considered our crops of Peas have been very good. The last two sowings particularly present a beautiful prospect, but are just now at a standstill, waiting for some sun to aid them to fill their pods.

BROAD BEANS.—These have produced capital crops this year. Those which I find do best in a damp climate are the Early Mazagan, Green Long Pod, Green Windsor, and Beck's Little Gem.

DWARF KIDNEY BEANS.—In the early part of the year this vegetable proved nearly a failure on account of the severity of the spring. To replace those lost I found it necessary to sow a quantity in pots and forward them by artificial means, which after hardening off well I planted out to supply blanks, and this answered the purpose well, giving a supply about the 25th of June. Those with which I have been most successful are Williams' Early Prolific, Negro Long-podded, and Canadian Wonder, which is excellent both for exhibition and table purposes. For the taller sorts I prefer the Champion, Scarlet Runner, and Painted Lady.

CAULIFLOWERS.—Our spring crop was a thorough failure owing to the severity of the weather. The only heads which we expect to turn in now are the Walcheren and Veitch's Autumn Giant, which we hope will be closely followed by Grange's Autumn Broccoli.

BROCCOLI in general does not come to perfection in this locality. I give the preference to Grange's Autumn Giant, Snow's Winter White, and Backhouse's Winter Broccoli, and for spring and early summer use Frogmore Protecting, Veitch's Protecting, Williams' Alexandra, Carter's Summer, and an exceedingly good variety, a cross between Cattell's Eclipse and Knight's Protecting, this coming into use through May and continuing until the middle of June; it is quite dwarf and compact.

BRUSSELS SPROUTS do very well here, especially when planted early. I am quite content with Dickson's Improved. It is a splendid variety, and suits our soil and climate well.

BORECOLE.—I find this to be a most useful vegetable for winter use, growing luxuriantly with us, Dwarf Green Curled or Scotch being our favourite.

CABBAGES.—I may mention a few of the very many useful varieties of the Cabbage family. The Early Dwarf York is very early, and consequently very useful; Wheeler's Imperial comes next, it is a splendid variety; Cocoa-nut is also very good; so is Enfield Market, notwithstanding it being a late variety.

SAVOY.—In this class our favourites are Dwarf Green Curled and Drumhead.

SPINACH.—This useful vegetable when sown in succession can be had at all seasons. I find for winter use none to equal the prickly variety, and for summer use the round suits best, sowings of which I make every eighth day during the summer months. The New Zealand or Flanders is very useful, but not a favourite with some consumers.

TURNIPS.—We had much anxiety this season concerning the welfare of the Turnip crop, all early sowings having bolted and were consequently useless; but those sown about the end of March and subsequently maintained the character for which the south of Ireland is celebrated, having grown to a good size and superior quality. The sorts which thrive best are the Early White Stone, Early Snowball, and Robertson's Golden Ball. For late sowings, Orange Jelly, Chirk Castle Black Stone, and American Red Stone. When sown at proper intervals these sorts give a good succession.

CARROTS.—For early sowings in frames the French Short Horn, and for sowing out of doors the Early Scarlet Horn, James's Intermediate, and Long Red Surrey. But the Carrot requires much attention to bring it to perfection in our climate, the wireworm being its greatest enemy. However, all have done well this year; but I may add that in the preparation of the ground I applied gas lime liberally, and to this I attribute the success of the Carrot crop.

PARSNIP.—This has been an unusually heavy crop with us this season. Parsnips like a deep soil, consequently I trenched to the depth of 3 feet, introduced plenty of manure to the depth of 15 inches under the surface, with a good layer of quicklime over all, which I had forked-in. The sorts I grow are Student and Hollow Crown.

BESTROOT.—This has been anything but a success this year, the seed being unusually slow in germinating, and those plants which succeeded in making their appearance above ground showed a great desire to run to seed. The sorts grown here are Cattell's Blood Red and Dell's Crimson.

ONIONS have fallen far short of being an average crop this year. The Globe Tripoli has not turned out as well as usual, growing luxuriant tops, but little bulb. Spring sowings are rather small, but of good quality. The sorts which suit us best I find to be Globe Tripoli for early use, and for general use James's Keeping, Bedfordshire Champion, Banbury Improved, and Williams's Magnum Bonum.

LEEKS are very good this season, Henry's Prize Leek being a capital variety.

CELERY is quite a success with us this year. I have been able to supply Celery of the very best quality since the 12th of August. The plan which I adopt for blanching in the early part of the season is to surround the plants with a quantity of sawdust, and then bank-up in the usual way. The sorts I grow being Williams's Matchless White and Williams's Matchless Red, and for latest Laing's Solid Red. I would recommend the above mode of blanching early Celery.

SALADS in general have given every satisfaction. A damp season like that just passed suits this class of vegetables well.

—A. CAMPBELL.

(To be continued.)

NEW BOOK.

The Clematis as a Garden Flower; being descriptions of the hardy kinds, directions for cultivation, and the purposes for which they are adapted in modern gardening. By THOMAS MOORE, F.L.S., &c., and GEORGE JACKMAN, F.R.H.S. New and revised edition. 1877.

THE title page from which the above is copied tells the purpose of the volume, and we readily record that the purpose is thoroughly effected. The *Clematis* is now one of the most ornamental and popular of our garden plants, but it took nearly three centuries to establish it in its present position, as is told in this extract from the introduction of the volume.

About half a dozen species of *Clematis*—all European—found their way to this country about the end of the sixteenth century—namely, *C. flammula*, *C. viticella*, *C. cirrhosa*, and *C. integrifolia*, all in 1596, and *C. erecta* in 1597. The two former still hold an honourable position amongst the ornamental species, though eclipsed by later introductions, and more especially by recent acquisitions of hybrid origin. The catalogues do not credit the seventeenth century with any additions to our garden *Clematises*; but in the course of the eighteenth century some few are recorded—*C. crispa*, *C. viorna*, and *C. orientalis* in the former half, and *C. virginiana*, *C. ochroleuca*, *C. florida*, *C. calycina*, *C. angustifolia*, and *C. paniculata* in the latter half.

Since the beginning of the present century the acquisitions

have been not only more numerous but more important; and to the introduction from China and Japan of *C. patens* and its varieties, of *C. lanuginosa*, *C. Fortunei*, and *C. Standishii*, we must ascribe the vast improvements which we now see in the Clematis—improvements which are probably unprecedented in the history of any of our popular flowers, when we take into account the number and variety of the acquisitions on the one hand, and the short space of time which has elapsed on the other. Taking them in chronological order, we find that this century gave us in its first decade *C. cylindrica*, *C. triterminalis* and *C. campaniflora*, plants now seldom heard of. In the second decade we find recorded *C. Simsii* and *C. reticulata*, both rather doubtful plants, and *C. chinensis*, now never seen. The third decade gave us *C. dahurica*, *C. lineariloba*, *C. biterminalis*, *C. terniflora*, and *C. japonica*. *C. grata* and *C. montana* were introduced in 1831, followed by *C. patens*, *C. Sieboldii*, and *C. latyrrifolia*, all in the fourth decade. Then came *C. graveolens* and *C. tubulosa* in 1845, and *C. Grahmi* in 1846; in 1851 the glorious *C. lanuginosa* was obtained; in 1854 *C. barbellata*; and finally, *C. Fortunei* and *C. Standishii* in 1863.

It is from these materials, or rather from a small proportion of the later introductions—*C. patens*, *C. lanuginosa*, *C. Fortunei*, and *C. Standishii* especially—that the magnificent varieties of Clematis now within reach of cultivators have been obtained.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

CARISSA GRANDIFLORA. *Nat. ord.*, Apocynaceæ. *Linn.*, Pentandria Monogynia.—“A very pretty evergreen bush, with white fragrant flowers and deep green leaves, of easy culture in a moderate stove or warm greenhouse during winter, and in a greenhouse or the open air in summer. It is a native of Natal, where it was discovered by Drege, and has been since collected by Peddie, Krauss, and other travellers. We have also seen specimens from St. Helena, where it is cultivated. *Carissa grandiflora* was introduced by Cooper when collecting for Mr. Wilson Saunders; in a note to the herbarium specimen which he sent home he gives it the native name of ‘Amatungula,’ adding, ‘fruit used for jam, tarts, &c.’ Harvey states of the African *Carissas* generally, that the fruit is plum-like and delicious. That of the Indian *C. Carandas* is eaten both raw and cooked. It flowers in the Palm house at the Royal Gardens in May. It has narrower leaves and much larger flowers than the native specimens and that figured in the ‘Refugium,’ which has also a greenish corolla, ours being pure white.”—(*Bot. Mag.*, t. 6307.)

TULIPA ORPHANIDEA. *Nat. ord.*, Liliaceæ. *Linn.*, Hexandria Monogynia.—“For garden purposes this is the finest of all the Tulips of the sylvestris group. It has flowers as large as those of sylvestris itself, but flushed on the outside with red instead of green. It is quite hardy, being an inhabitant of the mountains of Greece, at an elevation of from 3000 to 4000 feet above sea level. It has been for some time in cultivation under various names, having been discovered in 1857 on Mount Malevo in Eastern Læonia by Dr. Orphanides, Professor of Botany in the University of Athens, after whom it is named. Our drawing was taken from a plant which flowered with the Rev. H. Harpur-Crewe at Drayton-Beauchamp in June of this present year. In its native stations it flowers as early as April, or even the latter end of March.”—(*Ibid.*, t. 6310.)

NOTYLIA ALBIDA. *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—“It is a native of South America, from Mexico to Brazil. This species is one of the largest-flowered ones, though inferior in this respect to some others as it is in colour. Reichenbach well remarks that it resembles an *Eria* in habit and colour, or a small-flowered *Angraecum*. It was discovered by Warszewicz in Central America, and sent by him to the Royal Horticultural Society's gardens many years ago, since which time it has been re-imported by Messrs. Veitch, and first flowered April, 1872, in Messrs. Veitch's nursery.”—(*Ibid.*, t. 6311.)

MESEMBRYANTHEMUM COOPERI. *Nat. ord.*, Ficoidæ. *Linn.*, Icosandria Di-Pentagynia.—“This is a very handsome and free-growing species of *Mesembryanthemum*, filling a large pot with its blue-glaucous glistening stems and foliage, and bearing a handsome purple flower. It belongs to the *Crasulina* group of the *Papulosa* division, but differs very much from all previously described species, all of which have very slender stems. Its precise habitat is unknown; it was sent by Mr. Cooper when collecting in South Africa for Mr. Wilson Saunders, who, with his usual liberality, presented specimens to Kew, which flower annually in the month of June.”—(*Ibid.*, t. 6312.)

TOVARIA OLERACEA. *Nat. ord.*, Liliaceæ. *Linn.*, Hexandria

Monogynia.—“This is far the most striking of the eighteen species of *Tovaria*, a genus better known by its much later name of *Smilacina*. It is an inhabitant of the temperate region of Sikkim, at an elevation of from 8000 to 12,000 feet above sea level, and, as might be expected, proves to be perfectly hardy in English gardens. It was gathered first by Griffith, in 1849 by Sir Joseph Hooker, whose sketch made on the spot from the living plant is now in the Kew collection of drawings, and recently by Dr. Treutler and Mr. C. B. Clarke. It is the *Smilacina* described without a name by the latter gentleman in the account of his journey from Darjeeling to Tonglo, printed in the fifteenth volume of the Journal of the Linnean Society. We owe its introduction into cultivation to Dr. Treutler, who presented some of the rhizomes which he brought home to the Kew collection, where they flowered in the herbaceous ground this present summer. According to Dr. Hooker's note (see his Himalayan journals, vol. ii., p. 48) it is called ‘Chokli-bi’ by the natives of Sikkim, and its young flower heads, sheathed in tender green leaves, form an excellent vegetable, and it is to this that the specific name ‘*oleracea*’ alludes.”—(*Ibid.*, t. 6313.)

EPIDENDRUM SOPHRONITIS. *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—“Perhaps the most curious characters of *E. Sophronitis* are the broad honeyed area of the lip, and the most singular pale glaucous greenish waxy secretion that clothes both surfaces of the leaves. *E. Sophronitis* is a native of Loxa in Peru, where it has been collected by Wallis and others. The specimen here figured flowered in the Royal Gardens in May and June of the present year, and was received from Mr. Linden.”—(*Ibid.*, t. 6314.)

CEROPEGIA BARKLEYI.—“This is one of many undescribed species of *Ceropegia* which seem to abound in the dry regions of South Africa. *Ceropegia Barkleyi* flowered at the Royal Gardens, Kew, in May of the present year, from tubers sent to H.E. Sir Henry Barkly, K.C.B. (late Governor of the Cape Colony), from the Morley mission station in the Transkei district, by Mr. Bowker. It is allied perhaps most nearly to *C. africana*.”—(*Ibid.*, t. 6315.)

BORONIA ELATIOR.—“It is a tall shrub with hirsute branches, having pinnate dark green leaves, the flat linear rigid leaflets varying in number from five to thirteen or more. The flowers are axillary and pedunculate, bell-shaped, of a lively rosy-carmine hue, fragrant and very attractive, profusely decorating the branches. It is, indeed, one of the most beautiful of the *Boronias*, and is, as we learn from the Messrs. Veitch & Sons, by whom it has been introduced to public notice, a plant of remarkably easy cultivation. It was awarded a first-class certificate when exhibited by them at South Kensington in May, 1876. *Boronia elatior* is a native of Western Australia, in which colony it is found at King George's Sound, on the Darling Range, and at the Franklin River. It was formerly named *B. semifertilis* by Von Mueller. The colour of the flowers is much richer and more striking than that of the other *Boronias* already in cultivation.”—(*Flor. and Pom.*, 3 s., x., 145.)

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

HARDY FRUIT GARDEN.

OUR main work has been gathering fruit and storing it for late use. Nearly the whole of the Apples may now be gathered except the very late sorts. There are some sorts too that are not so late in ripening, that are very liable to shrivel if they are gathered from the trees as soon as the pips change to a brown tint. Of sorts liable to shrivel may be named Court-Pendul-Plat, Pitmaston Golden Pippin, Mannington's Pearmain, Reinette du Canada, and Earn's Pippin. There may be other sorts, but those named are better to hang on the trees as long as they will do so without injury. It is rather difficult, too, to know the right time to gather Pears. We usually gather them at intervals of a week or ten days from the same trees, and this prolongs the season in which they are fit for use. It is best to handle all fruits very carefully intended to keep, placing them one at a time into the baskets and also lifting them out by hand. A little clean hay or straw should be placed in the bottom of the basket into which the fruit is gathered.

We have already urged the importance of purchasing early in the season all fruit trees intended to be planted, and if the advice has been taken the trees will be ready to be sent home early in November, which is as early as they ought to be moved, especially as it may be necessary to send them a considerable distance. If the places have not been prepared for them this ought to be seen to before the ground is saturated with the usual rains we

have at this season. When the ground is wet it not only requires more labour to wheel the barrows, but moving very wet soil if it can possibly be prevented is a great mistake. The amount of preparation must be determined by the state of the ground. We have sometimes had to dig out a foot in depth of gravel under the trees in order to obtain sufficient depth of soil; at other times it has been necessary to dig out stiff clay and mix sandy material with the compost. Some soils must be well drained, others would not be benefited at all by draining. Usually the stiffer the soil the more necessity there is for draining. Something also depends on the district, whether it is high or low; the rainfall also must be estimated, as this ranges from 20 inches on the east coasts to 36 inches or more annually on the western. Lichens and Mosses of sorts covering the stems of the old trees is a sign of stagnant water in the soil.

Gooseberry and Currant bushes which have been covered over to preserve the fruit for as long a period as possible should have the coverings removed on fine days to allow the fruit to dry, and at the same time all mouldy berries should be removed.

No time should be lost in getting Strawberry plants out before the severe weather, which we may soon expect, sets in. If they are planted at once they will grow considerably before the winter, and would even bear a few fruits next year, but they cannot be expected to carry a full crop when they are planted late. Our own plants are now of large size, and the ground between the rows has been frequently hoed. The beds ought to be free from weeds at this season, for it is difficult to hoe them later.

PINE HOUSES.

It is now a good time to re-arrange the plants for the winter, and to take the opportunity to thoroughly clean the glass outside and inside, as also the woodwork of the houses. The tan beds should also be turned over, and if necessary a little fresh tan may be added; but this ought only to be done in the case of those plants that require to be incited into root-action, which includes recently-potted suckers and plants which are now throwing-up their fruit, or where the Pines are swelling. Plants intended to be started about three months hence should be kept quiet in a temperature of 60° at night, or even 55° in very cold nights, and the bottom heat should not exceed 80° or 85°. Pines are not unfrequently crowded too closely together, and added to this the plants may be too far removed from the glass; good fruit cannot under such circumstances be produced. The plants like plenty of light and with it as much air as possible. During the late autumn and winter months the Pine houses must be kept in a proper condition as regards atmospheric moisture. After this time it is better not to have moisture evaporate from the troughs fixed on the pipes. Sprinkling the paths and possibly the walls of the houses twice a-day will be sufficient. In fine weather admit as much air as possible. We would rather have more heat in the daytime from the pipes so as to admit a circulation of air, than to maintain the same temperature with closed lights and no artificial heat. Watering at the roots requires to be done with caution.

ORCHARD HOUSE.

The trees were repotted some time ago and are now fairly well established in their pots. Some of those not potted have been top-dressed. Mr. Rivers was the first to distinguish between top-dressing and surface-dressing, and it is a distinction with this difference, that at this season a large portion of the surface soil in the pots is removed with a piece of iron resembling the tine of a fork. This is replaced with rich soil composed of equal parts of loam and decayed manure. It is pressed down firmly with a wooden rammer similar to that used in potting the trees. Surface-dressing is merely adding a little rich compost to the surface in June and July without disturbing the roots at a time when the trees are in full growth. To form handsome trees it is necessary to purchase "maidens," and to pot them in 10-inch pots as early as the trees will bear removal. It is frequently necessary to cut a considerable portion of the roots off in order that the tree may be easily potted, and we have not found the trees suffer from this severe cutting-in. The potting material is very simple, merely good turfy loam four parts to one of decayed manure. We drain the pots well and press the compost in quite firmly, working the soil in amongst the roots. It ought to be noted, that if the trees are sent from the nursery they should be carefully lifted, and some damp moss or something similar should be placed round the roots. We have often wondered whether the fruit trees sold at auctions in London ever succeed well; they lay about in draughty places for days together with nothing round the roots until every fibre is shrivelled. Such trees may be sold cheaply, but they must be dear in the long run.

GREENHOUSE AND CONSERVATORY.

A frosty night or two came as a warning to remove all the Cape and New Holland plants into their winter quarters, as they not only suffer from frosts but we may expect continuous rains, which will do much injury by saturating the soil and causing the death of the small fibrous roots. There are scarcely finer plants at this or any other season of the year than the *Lapagerias*

alba and *rosea*, and after their culture is understood few plants are easier managed. We have been potting layers which were pegged down rather more than twelve months ago. The young plants had formed quite a mass of roots, many of them as thick as a goosequill; these were carefully preserved, and the plants were potted into pots that seemed large for the size of the plants, but were necessary to preserve the thick brittle roots. The pots were well drained, and the potting material employed was simply light fibrous peat; in this the roots luxuriate with the greatest freedom. *Lapagerias* are sometimes placed in heat: this is a mistake, as the plant is almost hardy and will suffer from too much heat. To grow it well it must be kept rather cool during summer. In our hot dry district a house facing north is the best place for it, and when it is grown in a house well exposed to the sun it is best to shade the plant from it. We syringe the leaves twice a day, and keep the roots always in a moist medium.

A few aphides had settled on the stage *Pelargoniums*, but two nights fumigating with tobacco smoke checked their further progress. *Cinerarias* were also fumigated for the same reason. This pest must be destroyed on its first appearance, or, what is better, fumigate when the plants seem quite clear, as preventing is better than destroying them after they have gained a footing. Where plenty of flowers are wanted at this season Zonal *Pelargoniums* and *Fuchsias* are suitable plants to grow, as they may be kept in flower until the *Chrysanthemums* are ready to take their place. In a week or ten days it will be necessary to take all the *Chrysanthemums* under glass, as the frost, should it set in severe, will damage the buds, especially those that show colour.

FLORIST FLOWERS.

Dahlias are still in great beauty where the frost has not touched them. This grand old flower when planted in a suitable position is still a very king amongst autumn flowers. The great many coloured globes nodding on their slender stalks have always an imposing effect. They are best either planted as a background to other flowers or as a foreground to a shrubby border; but those who grow for exhibition generally prepare a piece of ground by trenching and manuring, and plant the *Dahlias* in beds with about 4 feet between the plants. The flowering growths must be thinned out at this season, and all flowers which are past their best should be promptly cut off.

Hollyhocks have now mostly finished flowering; if so, the stems must be cut off near the surface of the ground—just above where the young growths are likely to come out. About the end of October the plants should be lifted, varieties that are scarce should be potted, and the ordinary stock may be planted-out close together where they may be protected from too much wet, which causes more injury to the plants than severe frost.

We have looked over the *Auriculas*, and have picked-off the withered leaves and any trusses of flowers that are coming up. If these are picked off at once the spring bloom will not suffer much from it, although it is certainly better when no autumn bloom requires picking off. Young offsets are potted off as they require it, but we shall not pot any after the middle of this month; it is better to allow them to remain until the spring, say the end of February or the first week in March.

Many of the *Pinks* have longer stems this year than usual, but they are now branching-out freely. We have placed small sticks to them to prevent the stems from snapping off at the surface of the ground; this they will do in high winds if not supported. *Carnations* and *Picotees* are now fairly established in pots, and we remove the lights, except during high winds and heavy rains. The plants require a fair supply of water at the roots.—J. DOUGLAS.

TRADE CATALOGUES RECEIVED.

H. Cannell, Swanley Nurseries, Kent.—*Autumn Catalogue of Plants and Bulbs.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

CALEBOLARIA SOIL (*An Old Subscriber*).—We could find no insects in the soil.

PLANTAINS ON LAWN (J. S.).—We know of no mode of destroying them except by cutting them out with a knife or dropping oil of vitriol into the centre of each weed.

GRAPE CULTURE (E. C.).—Our "Vine Manual," free by post if you enclose thirty-two postage stamps with your address.

GERANIUMS (C. P. Bolton).—There are hundreds of varieties so nearly alike that they cannot be named from mere trusses.

FRUIT TREES FOR SOUTH-ASPECTED WOODEN FENCE (T. G.).—Of Pears, Beurré Diel, Glou Morceau, Passe Colmar, and Winter Nellis. Of Plums, Green Gage and Cos's Golden Drop.

GRAPES SHRIVELLING (Mrs. Thorneycroft).—The premature shrivelling of the berries of which you complain arises from insufficient moisture at the roots. Have the border thoroughly drenched with sewage when the fruit commences colouring, giving at the same time a surface-dressing of manure, and you will soon perceive a material improvement in branches, foliage, and fruit.

IVY NOT CLINGING—CLIMBING PLANTS FOR A NORTH ASPECT (F. J.).—Some kinds of Ivy do not cling readily to walls of any description, the leading shoots having to be fastened with shreds and nails. A cemented wall can be covered with Ivy in this way, but the branch roots never take very strong hold of such a surface because of its dryness, a porous surface capable of absorbing much moisture, as brick or stone, inducing a quick strong root-growth, which enters every crevice and spreads over the entire surface. Mr. Luckhurst has *Lonicera flucosa* upon a north aspect, and finds it answers admirably. You cannot do better than train it upon a trellis against your wall as you propose. A few other good climbers for such a position are *Cotoneaster microphylla*, *C. Simonsii*, *Crataegus Pyracantha*, *Escallonia macrantha*, *Ampelopsis hederacea*, *Berberis Darwini*, and *Ligustrum japonicum*. The address which you require is Messrs. Barr & Sugden, 12, King Street, Covent Garden.

PRUNING SUMMER GROWTHS OF FRUIT TREES (F. M. S.).—It is good practice not to prune yet, but to give each shoot a twist about 2 inches from its base, not breaking it, but turning it downwards so as to direct the full flow of the sap from the upper part of the shoot into the buds at its base, which thus become large and full without starting into premature growth. Prune when the leaf falls, leaving your spurs short or long as may be best suited to their position on the tree, from one to six buds being left on as is found necessary.

SEEDLINGS OF PANSIES, SWEET WILLIAMS, AND ANTIRRHINUMS (Idem).—Transplant from the seed beds immediately, in order that the plants may be well established before severe weather sets in.

GLOIRE DE DIJON ROSE NOT FLOWERING (Idem).—You need have no fear that this very free-flowering variety will not develop its true character eventually. As you wish your flourishing young plants to come early into flower avoid hard pruning, simply cutting off a few inches of the long shoots and nailing them horizontally along the wall to induce every bud to give growth next season. Continue your liberal treatment; it is hardly possible to overfeed a Rose so robust as this is.

BONE DUST FOR ROSES (Amateur).—It is a "good thing" for Roses, a large handful mixed with the soil employed in planting each plant, or it may be given in March, a handful sprinkled around the plant for a distance of 1 foot to 18 inches from the stem, pointing in lightly with a fork. Seedling Briars will require to make two years' growth, and in the third be budded, or so soon as strong enough.

FUNGUS ON WATER LILY LEAVES (W. J. C.).—We know of no means of destroying the jelly-like substance except to sponge it off. Probably some newts placed in the water would tend to lessen the evil by purifying the water.

LETTUCES AND RADISHES IN WINTER (E. R. P.).—A rich friable loamy soil is most suitable with about a fourth of well-decayed manure well incorporated. The soil should be placed about 8 inches thick over a hotbed formed of sweetened dung, over which is to be placed a frame, the seed of Radishes being sown in the early part of November. The temperature of the bed should be 65° to 75°, and the lights may be put on but withdrawn when the plants appear, the object being to prevent them from drawing and yet keeping them slowly growing. If the weather be frosty the lights must be kept on and frost excluded by a covering of mats over the lights in severe weather, the opportunity to give air being carefully attended to whenever the mildness of the weather permits. The temperature of the frame should be 55°. Gentle waterings will occasionally be required, also linings of fresh dung to maintain the requisite temperature of the bed. A sowing should be made every three weeks until the middle of February. The best kinds for forcing are Wood's Frame, French Breakfast, and White Forcing Turnip. We sow the kinds named on a border of light soil in a sheltered situation at the end of September, and they come in in early November, and give a supply until near Christmas, they being covered with straw in severe weather, removing it when mild. The China Rose and Black Spanish, sown at the end of August or early September, are fine for winter, they being protected from frost or taken up in case of severe frost and stored in sand. Rampons are also useful for winter salading, the seed being sown in May, the roots taken up in autumn and stored in sand. Lettuces should be sown for winter use about the end of July or early August, which will give plants if properly cultivated which may be transplanted in frames during November; they, being well ventilated and kept from frost, will give a supply until Christmas. They cannot be kept too cool, only exclude frost and wet. For plants to succeed them sow the third week in August on a warm border in rows 3 inches apart, and the length of the frames the plants are to be covered with. Thin the plants to 6 inches distance apart in the rows, and place on the frames in November. Air to be given very freely, and the plants kept from frost by litter placed against the sides of the frame, and mats with straw over the lights, removing in mild weather. They will succeed those transplanted in frames, and continue until the autumn-sown outdoor plants come in. Every other plant should be cut, which will give more room to the plants left. The best kinds for winter use are Cabbage—All the Year Round, Early Paris Market, and Stanstead Park; Cos—Brown Sugarloaf, Hicks's Hardy White, and Bath (black-seeded).

SOIL FOR FERNS (M.).—The bog peat is not suitable. Kent peat answers well, and so will the heath peat if brown, fibrous, and sandy. The brown fibrous bog peat will grow the stronger-growing kinds especially "tree" kinds well. We find a majority of Ferns to do well in turfy loam; indeed, the home of most Ferns is a loamy soil overlaid with vegetable matter, the debris of their own or previous vegetation. We advise, however, two-thirds of brown, fibrous, sandy peat, one-third of yellow turfy loam, and a sixth of silver sand, which will suit most kinds, whilst for the strong-growing sorts

we should not scruple to use the "brown, fibrous, bog peat," which as it grows Rhododendrons very well would grow Ferns; yet we have used black bog peat, and it became a soapy mass in which nothing flourished for a long period. Leaf soil from decayed leaves is objectionable for the same reason.

POTTING LILIUM ABRATUM (S. E.).—Mr. Wood cuts down the stems of his Lilliums at the same time that he pots them. He also gives each stem a slight twist and it comes out of the bulb; then there is no part left in the bulb to cause it to decay. Mr. Wood's bulbs have been potted rather more than a fortnight. The pots are plunged in leaf soil on a dry bottom, not in ashes, which when employed fresh contain sulphur, which is washed out of the ashes with rain and is injurious to the Lilliums. The plants are watered with liquid manure water as soon as the pots are full of roots until the flowers are ready to open, then soft water only is given. The bulbs are placed half way down the pots, good drainage being provided.

RENEWING VINE BORDER (C. W.).—We are situated where the subsoil and other surroundings are the same as yours, and have also had the Vines to shank similar to yours. Our plan, which has been successful, has been to dig a trench at that part of the border furthest removed from the Vines, the trench to be as deep as the bottom of the border; then with forks remove the old compost and raise the roots nearer the surface. Our Vines are planted inside, and the borders are both outside and inside. We only do one border at a time, and generally find all the best roots in the gravel underneath. We renew the border with a compost of good turfy loam eight parts, decayed manure one part, and to each cartload add a bushel of charcoal and a peck of crushed bones. Our borders are not concreted. Messrs. Backhouse of York could supply you with plants of the Campanula you require, but not very likely with seeds.

GREENHOUSE CLIMBER (R. M.).—Any of the London firms can supply the creeper you want, or will obtain it for you. *Bignonia Chamberlayne* with yellow flowers, or *Passiflora cinnabarina* with bright red flowers, would suit you. The common large-leaved Ivy is the best for covering walls quickly. We cannot recommend dealers in such plants.

SNOW PANSIES (C. J. B.).—It is best to propagate young plants annually. You will find a number of slender growths springing from the base of the plants; these are the best to make into cuttings, which strike freely now, or, indeed, at any season under hand-lights.

CHERRY TREE UNFRUITFUL (Idem).—It is not uncommon for the fruit to drop off as you describe. Root-pruning or lifting the tree altogether would not mend matters. Indeed, there is no help for it, as nearly all the varieties of Cherry trees throw off part of their fruit in a green state, some more than others. Governor Wood, May Duke, Elton, and Black Tartarian are free-bearing sorts.

CULTURE OF TYDEAS (J. A., Croydon).—These plants require similar treatment to Achimenes. Pot them in peat and leaf soil with a good proportion of silver sand. The plants like plenty of heat when growing. They also require a short season of rest, but the roots must not be too much dried, as they do not form tubers similar to *Genesiras* and *Achimenes*. After a short season of rest it is best to start them again.

HOLLYHOCKS (Quiz).—For treatment see "Doings of Last Week." Frank Gibb Dougal, James Laing, Mrs. Laing, and John Stewart, are good varieties. Six fine Dahlias are—*Artiste*, *Christopher Ridley*, *Canary*, *John Sandish*, *Ovid*, and *Herbert Turner*; and three of the best *Fuchsias* are *Avalanche* (Smith), *Mrs. Marshall*, and *Mrs. Cannell*.

LENGTH OF GREENHOUSE LIGHTS (L. F. C.).—You do not inform us whether the width of the house includes the side walls or is the interior width only. The back lights being 4 feet 8 inches you will need lights for the front part of the roof 5 feet 6 inches in length, presuming the whole width to be 9 feet, including the side walls, which should not be less than 9 inches thick, but should the width be 9 feet clear of the walls inside you will require lights for the front part of the roof 7 feet long. The lights should project 1 to 1½ inch beyond the walls. We should have the front of the house above 2 feet 8 inches from the floor line cased for glass, and every other light made to open, with corresponding lights in the upper part of the roof also to open for ventilation. As your house is not to be heated we should be content with such plans as will be useful to you in future years for forcing, such as *Deutzia gracilis*, *Dielyria spectabilis*, *Spiraea japonica*, *Prunus sinensis alba flore-pleno*, *Helleborus niger*, and *Tea-seeded* Roses. Clematises *Lady Londesborough*, *Miss Bateman*, and *Albert Victor* are very fine. With these and bulbs—*Hyacinths*, *Narcissuses*, *Tuipis*, and *Crocuses*, you may have an effective display in spring, especially if you add a few of the early-flowering *Rhododendrons*, and a *zalea pontica* in variety.

CANON HALL MUSCAT GRAPES STONELESS (Alfred Powell).—Stoneless Grapes betoken a want of vigour in the Vine. Is the soil thin and poor? If so, lose no time in applying a liberal surface-dressing of manure, to which add any such substances as wood ashes, mortar rubbish, burnt weeds, or chopped turf. How about the drainage and watering? Any defect or want in either respect does harm. If nothing is wanting in any of the points indicated, and the crop is abundant and fine, then we can only suggest careful impregnation next season with pollen of this or any other Grape, taking care to remove the globe of moisture so frequently found upon the pistil of the flowers of this Grape before you apply the pollen. Our reply to your inquiry is necessarily suggestive rather than conclusive, for you tell us nothing about the condition of the Vines.

HEATING A PLANT PROTECTOR (An Old Subscriber).—If you have any hot-water apparatus the best plan would be to run a 3-inch pipe round the sides. Such a pipe could, of course, be attached to an ordinary kitchen boiler. Failing the pipe, a small furnace and brick flue would answer very well, letting the flue pass through or rather under the centre in an open trench of brickwork, the top of the flue being a few inches below the bottom of the protector, with a grating or strips of wood over it, whereon plants might be placed, as the heat need never be so violent as to parch the roots, your object being only to exclude frost. One flue would suffice, the furnace being at one end, and the chimney with a damper near the bottom at the other end.

VENTILATION OF A CONSERVATORY (A Subscriber).—If by drawing down the blind and opening all the ventilators you cannot reduce the temperature to within a few degrees of that outside the house, then more openings must be made in the roof, where in any case there should be some ventilators near the ridge on the south slope, or how can you admit air when a cold north or north-east wind is blowing on a clear day? We are inclined to think there is something wrong in the watering. Do you give enough water during hot days? All the plants do not require water at the same time, and in hot weather they must be inspected three times a day, taking care that all neces-

sary watering is thorough. If any doubts exist about a plant, submerge the pot in water, and if bubbles come freely to the surface it is a certain sign that the centre of the ball is dry, and the pot must remain under water till bubbles cease rising.

REMOVING ROSE CUTTINGS AND BEDDING PLANTS IN WINTER (S. B.).—Take up the Rose cuttings and pot them immediately, and they will be well established in the soil by the time of your removal. Bedding plants may be taken out of the pots, the loose soil removed, the plants packed in hampers, and repotted at the end of the journey with perfect success. Especial care must be taken to pad the sides of the hampers with moss or hay to exclude frost, and not to overwater the plants when they are repotted.

VARIEGATED ASH AND CORCHORUS JAPONICA (Idem).—Both the yellow and white variegated forms of the Ash are now well known and widely distributed. The first is *Fraxinus aucubefolia*, and the other *F. argentea* variegata. *Corchorus japonica* variegata is also quite common. It will be better recognised under the more familiar name of Kerria. It is readily propagated by cuttings, young plants often being turned to good account in flower beds and borders, the slender growth and variegated foliage having a sprightly and very ornamental appearance.

TERRA COTTA STOVE (J. C. B.).—Our correspondent asks for information from any reader who has used one successfully without piping to heat a very small greenhouse.

CELOSIA (E. R.).—The roots must be kept active. Apply a little tepid liquid manure.

SEA SAND FOR GARDENS (An Old Subscriber).—The value and usefulness of such sand for the propagation of cuttings and raising seedlings altogether depends upon the proportion of saline particles which it contains, a superabundance being likely to prove fatal to tender growth of seedlings. You can, however, readily test it before accumulating any quantity, and we shall be glad to learn the result. Sand impregnated with oxide of iron is fatal to most, but not quite all seedlings. The seed vegetates freely enough in it, but the cuticle of the seedlings is destroyed so quickly that every plant disappears in a few days. The sand and half-decayed mussel shells will undoubtedly prove highly beneficial to your stiff loam.

NAMES OF FRUITS.—Our best authority being absent our correspondents must wait a week or two for the identification of fruits they have sent.

NAMES OF PLANTS (J. G. G.).—1, *Aspidium angulare*; 2, *Asplenium flaccidum*; 3, *A. Hookerianum* (?); 4, *Dicksonia antarctica* or a close ally; 5, *Blechnum occidentale*; 6, *Onychium japonicum*. (*E. A. P.*)—5, *Cystopteris fragilis*; 6, *Polypodium Phegopteris*. (*John*).—1, *Pteris serrulata*; 2, *Pteris cretica*; 3, *Lygodium japonicum*; 4, *Selaginella uncinata*. (*W. W. A.*)—*Ceratopteris thalictroides*. (*E. H. B.*)—*Tritonia aurea*. (*Grilloote*).—*Hedychium*. (*J. C.*)—1 and 3, *Nephrodium dilatatum*; 4, Probably *Nephrodium molle*; 2, Indeterminable. (*J. P.*)—1, *Veronica spicata*; 2, *Isolepis gracilis*; 3, *Achillea millefolium*. (*H.*)—*Aster Tradescanti*? (*I. E.*)—*Nicanthera physaloides*. (*M. B.*)—*Lysimachia vulgaris*. (*John Horton*).—It is probably a *Cotoneaster*. (*Murck*).—The Field Sow Thistle (*Sonchus arvensis*).

POULTRY, BEE, AND PIGEON CHRONICLE.

THE OXFORD POULTRY SHOW SCHEDULE.

The sixth Oxford Show is to take place on October 24th and 25th. The career of this favourite Show has been a successful one. It has increased in popularity and strength until now it has become nearly the second in importance. We hope Oxford has not yet gained the summit of its success, and that when it does reach it that there it may remain. Too large a committee generally do more harm than good, but when only the names of two or three gentlemen appear upon a schedule as the committee many wonder why more neighbouring fanciers have not embarked in the enterprise, and are wont to fear that some sort of private speculation has been the cause. We can tell of one or two great shows which began with a certain number of committeemen, and allowed that number from various causes to decrease until only two or three gentlemen remained, who, having the reins in their own hands, tried to ride roughshod over exhibitors, and they failed. We trust this may never occur to Oxford. There are many good fanciers in the city and its environs, and we hope that, as the number from any cause lessens of the present Committee, the ranks may be replenished. It has not been done hitherto, for we can remember other names in the list which do not now exist; some because removed by death, and others from resignation; and now we learn that two more of the number intend to take their names from the list of the Committee after this Show. We have even heard that the Secretary has in contemplation the removal of his name as well. For the sake of this Exhibition we must here publicly beg him to continue, for there is no other gentleman connected with the Show who could manage the working of this Exhibition.

The schedule this year is better than ever. Its excellent classification is remarkable, for nearly every existing breed is here provided for. There are as many cups for the poultry as there are weeks in the year, while Pigeons have also a very large number; and for all these pieces of plate, liberal prizes, and the entry fee is only 6s. a pen for poultry and 3s. 6d. for Pigeons. We do trust all exhibitors will note this, for in these days of frightfully exorbitant entrance fees a show whose prize money is large and the opportunities of obtaining it so inexpensive requires hearty support. Among the rules we note that all the modern improvements are in vogue here, and we see that the Committee rightly reserve the power to refuse any entries and to elect an additional Judge if required, but we confess we

see with regret that the price of a catalogue is raised to 1s. It is far too much, and we heard at Ipswich loud and frequent complaints of the price of the catalogues, though they were, as they are at Oxford, got up in first-class style. Among the various classes for poultry we will only touch upon the particular ones. Black Cochins breeders will hail their class surely with gladness after the insult they have received at the Alexandra Palace, where they are entirely omitted, while their cross-bred allies the "Long-shins" have a class and a cup. Black Red Game cockerels here have a £10 cup and pullets a £5 5s. one, while there is also a £3 one for undubbed cockerels. Polands, Blacks, Silvers, and Golds, each have a cup, and so have Brown and White Leghorns, Silkies, Sultans, Andalusians, and Malays. For the Variety class there remain only La Flèche, Minorcas, Chamois, Polands, and such odds and ends. The Waterfowl have grand opportunities of showing themselves. There are classes for Aylesburies, Rouens, Black East Indians, Pekins, Call, Mandarin, and Carolinas, and any other variety not before mentioned. Pheasants, too, have a class, and Turkeys and Geese each a cup. Six selling classes with an entrance fee of 5s. per pen and twenty-three prizes finish this section, where the awards will be made by Messrs. Hewitt and Teebay; and the various classes each gentleman will adjudicate upon, as well as the allotted portions in the Pigeons to Messrs. Allsopp, Esquilant, and Jones, will be next week announced in these columns. The entries will close on Saturday, October 6th, but entries posted on that day will be in time. The Pigeons have seventy-five classes, of which Dragons have eighteen, Carriers eight, Tumblers six, Antwerps seven, Owls five, Jacks five, Pouters five, Turbits four, Magpies three, Fantails two, and Nuns, Archangels, Swallows, and the Variety class one each.—W.

THE AQUARIUM PIGEON SHOW.

SECOND NOTICE.

In resuming the subject of the Aquarium Show I would begin by stating that I never at any show saw the birds better looked after. Food supply, water supply, sand, all excellent. There are some occupations—would there were more—suited to women, and among them the care of birds, but until recently I never saw this work in the hands of a woman; but at the last Show, as at this, the chief feeder was a daughter of the late Mr. Cummins, a fancier of former years. Well did Miss Cummins do her work; she delights in the birds, and loves to be among them. Such a good feeder is a gain to fanciers, and I hope to see her employed at other shows.

In future poultry exhibitions at the Aquarium I hope the Pigeons will have the gallery, where they could be well seen and no pens be one above another. I now am standing in front of the Blue Pied Pouter cocks. Here the chief object of interest is the bird who wins Captain Hill's challenge cup value fifteen guineas, the same bird to win it three times. The same owner and bird have won it twice—Mr. McCulloch of Belfast; but Mr. Baker's bird won this time. Both on Tuesday and Wednesday this bird was so hopelessly out of show when I saw it—a mere mass of misery, with its crop hanging, that I could not judge of its merits; as show, or even move, it would not. "Sick and sad" was my verdict. The other bird of Mr. Baker's does not call for particular notice; but, as recorded last week, the very highly commended of Mr. Fulton will be the bird of the future. The Black Pied—These are getting more slender, but are they quite as good in colour by the crossing to get the slenderness? This first was also, with shape and half-moon, also of a good colour. The Yellow and Red cocks.—First a Yellow, second Yellow also, but poor in colour; third a Red; very highly commended (567) capital as a Pouter, but too gay in crop. The White Pouter cocks formed an excellent class, one getting cup. The third (Mrs. Ladd) was sadly in moult. If the White cocks were good the White hens were even better. Messrs. Ridley and Dye were the most successful. The Blue Pied hens were less to be remarked, while the Black Pied shot clear above them, the cup hen having limb, colour, and shape, and being altogether excellent. The Yellow hens—first Ridley & Dye, the best Yellow in the Show. The other colour and marking cock or hen had as Al a good Mealy of the true colour, with the usual Mealy excellence in shape, good globe, and great length. The Pigmies were in both classes very numerous, and the effort to breed them of standard markings seems to be more and more successful. The first hen was really a good Blue Pouter in miniature colour, bars, and shape; and the third cock was the same, but not so good; while the third hen was a fair Blue but bishoped.

Passing on I reach the Carriers. As showing how rare is very great excellence in fancy birds, as in everything else, here were only three to compete properly qualified as having won not less than three first prizes of value. Mr. Ecroyd's bird, which cost him £100, was winner, but the two next were close upon his heels, particularly the Dun. There the three birds stood, the cream of the Carrier world. Among the old Black cocks Mr. Hedley's, though ragged with moult, was first, as he deserved to be; a fine three-year-old bird. As a class the old Black cocks were excel-

lent; Cucksey second, Stretch third. The Dun cup bird (Mr. Hedley's) all he should be save in colour. The Blue cocks.—First a good wattled bird, and in build, &c., no Dragon; second cloudy in colour but a fine Carrier. White or Pied cocks.—First White, too short in face; second White, a capital shape; third an old friend, Mr. Ord's Mottle. Carrier hens, Black.—Cup (Fulton) a very rag from moult, but grand though a rag. Dun hens better than Blacks. Blue hens.—First a bird of shape, second strong and large.

Young Black Cocks.—Last week spoke against the cup cock, so I see no reason to reconsider my words. The first Dun was good in colour, narrow in head, and very promising. In Black hens the Judge was all right in giving the cup to Mr. Heritage's bird. The Dun and Blue hens call for no comment.

Dragoons.—Blue and Silver cocks good, especially the former, but the great praise must be reserved to the Red and Yellows. The cup Red (Sargent's) was simply splendid, in deep colour and proper Dragon formation; an excellent Yellow came second, and a good one third. The White cocks very few. There was a class for Blue-chequer, and Red-chequers also appeared. These colours are too much associated with Antwerps to be very pleasing in Dragoons. I think special Chequer classes a mistake; better to keep to the established colours, admitting, however, Grizzles to a class. The Dragon hens, Blues.—Second a very charming bird, but as a class very inferior indeed. Silvers.—First really good. Red and Yellow, however, the queens among the old Dragoons. Cup an excellent Yellow in colour and properties. Blue-chequers better absent. Among the Dragoons of 1877 the Silver-cup bird (Mr. Wood's) much the best. I come now to the Short-faced Tumblers. Almond cocks.—First and cup (Henning)—head, beak, carriage, a gem; second good carriage; third old and rich in colour. The old Almond hens not remarkable. Now I come to the birds hidden under the upper tier, and these were unfortunately such birds as require a strong light to see their full beauty, such as Almonds and other delicately-shaped Tumblers. Among these latter Agates seem now to bear the bell, and very good and pretty birds were shown. The Black Mottles were, as always, few but very choice, and the cup bird charming. As to Balds, where were Mr. Woodhouse's birds? None shown were quite up to the mark. Barbs next, and the old ones certainly good, both in Blacks, Reds, and Yellows. Mr. Frith's cup Black cock was supreme in excellence, though Mr. Hedley's Red pressed him close. Among Barb hens Fulton's Yellow (1080) pleased me best. The young Barb cup hen (1092) was alone much distinguished.

Next Jacobins, which appeared to give the Judges much trouble, and in spite of the moult, and the pens of some were carpeted, were excellent in all classes. We get now in Jacobins "lots of stuff," length of feather; but there is, yes there is, oh! fanciers, too great coarseness in the Reds and Yellows. This fault needs removal. Red cocks a very good class. First long in feather but not fully moulted in tail, not quite as dark in thigh as he ought to have been for his high position. The Red Jacks have now become very good in colour. Colour of Yellows as a rule good also. First Yellow cock a little too long-faced and not down-faced, second in miserable moult, third a first-rate bird, though placed third. But if Reds and Yellows good, Blacks much better. I quite agree with Mr. Fulton that the Black Jacobin is the Jacobin from contrast of feather. Cup bird a very gem in hood, eye, face, and colour; a great credit to Mr. Heritage's loft. Third better than second, except that it was short in flights. Red, Yellow, and Black hens good. Then came those most charming Pigeons the Whites, at present shown cock or hen. Of all fancy Pigeons these and the African Owls best deserve the title of "pretty." Mr. Salter's cup bird a very exquisite Jacobin; his second good; so also Mr. Baker's third.

Any other Colours, Cock or Hen.—An interesting class. Here were Mottles from which the Whites are made, and the pearl eyes kept up. First a Mottle, second a Dun, third a Strawberry. The two latter the result of crosses, but as Jacobins excellent. Fantails, prizes for both English and Scotch birds. I hope one style only would be shown everywhere, the compound of English and Scotch. The cup English bird all that is wanted, shape and motion without super-motion. Fantails, any other Colour.—The winners as usual being all Blue. Nuns.—A neat nice lot, and as I recorded with pleasure last week, a Red one won a prize. Trumpeters.—Ten pens, and eight of them good. Swallows.—First a Black, second a Red, third a Blue. These are great ornaments to a show. Archangels.—Cup bird alone in great superiority. The champion class of English Owls brought of course few, but the best in the fancy, four birds only, and all noticed. Mr. John Ecroyd, the champion Carrier winner was champion winner here too. The next classes of English, Blue or Powdered Blue, and Silver or Powdered Silver, brought only one real Powdered Blue and one real Powdered Silver, but as Owls these classes were capital, and more than half were noticed, but semi-powdering is not enough. The other classes of English Owls were, too, very good, and a Silver hen (Salter's)

took cup No. 45. Foreign Owls much less numerous. A beautiful Blue (Wilde's), took the cup. The other winners were White. Turbits a show of themselves, pretty Pigeons now seem thoroughly appreciated; 119 Turbits to sixty-five Pouters. Never before so many Turbits seen together. The cup went to a Black (Mr. Ecroyd). Altogether nearly sixty Turbits received some notice. N.B.—I am glad the Shell-crowned had a class.

Maggies made-up in goodness what they lacked in numbers. A Black bird won cup No. 48. Runts a little more numerous, and as one had a cup we may expect to see more next time. The Flying Tumblers, Balds and Beards.—The former the best. Then the Any other colour brought Mottles and whole colours of great beauty. These two classes give humble fanciers a chance.

A beautiful class of Short-faced Frilled varieties followed, such as Satinets, Turbites, &c., and attracted much attention from non-fanciers, and more than half being noticed showed their excellence. Antwerps of the two varieties and the Selling classes brought up the rear, together with a special Flying class.

Such was this beautiful Pigeon Show of nearly 1200 birds. It was held a little too soon in the season, especially such a season as this, but it was very beautiful nevertheless. The time has now come, I think, for, in London, the Pigeon Shows to be separated from the poultry; there is not sufficient room for both. Then, again, a very large proportion of Pigeon fanciers reside near London. The Pigeons can now stand by themselves, and are more pleasing to London visitors than poultry. —WILTSHIRE RECTOR.

OUR DUTY TO OUR FOUR-FOOTED AND FEATHERED NEIGHBOURS.—No. 5.

CRUELTY TO PIGEONS—THE SHOOTING MATCH.

In speaking of the cruelty to Pigeons entailed by a shooting match I will not draw upon fancy in the least degree, but upon memory. A group of boys in an east of England school—an old-fashioned grammar school, and strange to say held in the south transept of the parish church (transept then walled off, now properly thrown into the church at a recent restoration). These boys were debating one cold winter's morning upon the news of a Pigeon match and the desirability of asking for a holiday. The poor master—worn with troubles and ill health, never loth to give a holiday unless he thought the parents would be offended—after a show of resistance to the request soon yielded; then followed the brief and hearty thanks, then a rush was made to the door, and away the lads run—waving their caps, shouting their joy. Boys must make a noise if happy; the buoyant spirit must break out in cheering, and laughing, and shouting. Is not a nursery with healthy children in it always a noisy place? By the way, is there any pleasure so great on this old earth as that of a schoolboy's holiday? Only a day, a brief day, and then back to desks, and books, and slates; yet all are forgotten, all disappear as by magic. The arithmetic dunces forgets even the hated rule of threes. To-morrow the school work will begin again; but that will be to-morrow. To-morrow in a light-hearted boy's mind is a hundred years hence. To-day is life, and life to be enjoyed. Oh! early days, when the blood is quicksilver.

"Bliss was it in those days to be alive,
And to be young was very heaven."

No competitive examinations then in my day, no priggish lads who were all work and no play. We didn't like work, and we did like play; and oh! we did enjoy a holiday. No city clerk enjoys his bank holiday more; not so much, poor fellow, I wish he did; but his happiness is dashed by the thought of the mill and its same dreary round which will begin again to-morrow. It is only the boy forgets the coming morrow.

But how about the Pigeon match? We joined the concourse of men and boys who, a thick-packed crowd, were going to the place of meeting, hampers full of Pigeons preceding us. I soon began to feel ashamed. All the rascality of the town were in the crowd. It was a beer-and-tobacco-smelling crowd, even at that early hour. It was a cursing swearing crowd and a betting crowd. No girl or woman was there, whose presence has a wonderfully restraining influence; they absent, bad men grow worse. The ground for the shooting is reached, the trap set up, and I hasten to the baskets—I, a young Pigeon fancier—to see the Pigeons. There they are, crammed into hampers with no room to move; but crowded many deep, so deep that afterwards it was found several at the bottom were dead. There are the poor birds wing over wing, head over head, pecking each other and struggling. Then they are not even the so-called Blue Rocks, not even the Blue Dovehouse Pigeons got from the farmers' dovecotes in the country, but any mongrel. Here a feather or two on the neck showing a Jacobin cross, there a long beak showing a Dragon cross. A little man in a fur cap supplied the trap. Why is it that a fur cap is a sure indication of a scamp? But so it is. Dickens has represented the blackguard in "Our Mutual Friend" with that head-covering. When the poor wicked wretch of the story had been nearly drowned and

was slowly recovered by the doctor his first words were, "Where's my fur cap?"

Beware of a man who wears a fur cap, especially if he has little leering red eyes. If he is an undersized man he is a crafty rogue, if a big man he is burglariously inclined. "Fur cap" puts the first bird into the trap, which being suddenly opened reveals the poor scared thing standing on the little platform and too frightened to move. Driven away with stones it flies straight towards the shooter, and towards death; happy bird, one shot and dead. Not so other birds. They are not so fortunate, the shooter misses or he wounds only; a few feathers fall, but the bird flies on. Was there but one gun the matter would not have been so bad and the contest not so unfair, but out of the marked ground in fields all round were scouts—hobble-de-hoys armed with all sorts of rusty guns. The poor escaped or wounded birds have to run the gauntlet of these; bang, bang all round, and continuously. Some of the birds that were out of reach get across back again, and are again into the fire, so confused are they; of course, there are some Pigeons—the cleverer fliers, probably half-bred Dragons or Skinnams—who, on being missed by the shooter, rise clear up, and being above the shot of the scouts go off straight to their homes. I knew one such bird in another part of England who was sold every winter for the shooting, and always came back untouched. The farmer used to look out for him soon after the shooting began and watch him fly back, and call the children with, "Here's our old Tom back again." But such luck is very rare.

But to return to the match at which I was present. I stood usually near to the shooters, two of whom were very much the observed of us all. One—a low class man who had married a widow with good means, and whose "get up" was of most elaborate sporting style then in vogue; poor fellow! he soon after got to his regular pint of brandy a-day besides other drinks, and of course he died. But another, and the very best shot there, was still more noticed by us boys, for some years before he had been at our school. He was now just of age, and had come in for a considerable property, soon alas! to be all run through. Then there were the sporting tailors and shoemakers, &c., who were betting pence on either gun or bird; and quarrels consequent upon the betting till the whole air rang with bad language. As to pleasure, nobody seemed pleased unless it was some scout who had managed to bag a Pigeon or two. Towards afternoon the cold and damp with the wind came up from the fens, and we boys, even with hands in pocket and jackets buttoned-up, shivered to the bone. Oh! those dreary ugly old fens! how the cold damp of them seemed to enter into one's limbs, how the water mills turned by the wind seemed as evening came on (I have counted twenty-five from one site) to grow bigger until they had a weird, uncanny, ghostly look, and I go home hungry, cold, and unhappy. Why unhappy? Because I had witnessed cruelty to poor birds—shameful cruelty, unfairness to the poor things; and then what had I heard and seen around?—bad language, drunken blood-shot eyes, and bloated faces.

Are Pigeon matches now-a-days as bad as this? Some may be, though manners and morals are better than formerly. But there has come another feature—women attend them. Ladies, dainty ladies, whom a drop of blood affrights, give their presence, and they go to what has been called in refined words "a tournament of Doves." A wrong title, for a tournament means a mock encounter, and it is the reverse to the poor Pigeons. Legitimate sport there is among the stubbles on an English September on the hills after the grouse; but a Pigeon match is not fair sport—cruelty before it begins in the crowded hampers, cruelty at the time, and cruel suffering to the poor wounded birds afterwards as they sit moping and miserable in their lofts. Would that all felt what I a boy felt—shame and disgust; and did as I did, never be present at another match.—WILTSHIRE RECTOR.

BEES AT FLOWER SHOWS.

THE experiment of holding a bee and honey exhibition in conjunction with flowers and fruit has during the present year been tried with unvarying success at Weston-super-Mare, Taunton, Dorchester, Wolverhampton, Sherborne, Carlisle, Grantham, Berkhamsted, and at least half a dozen other places, and has tended not a little to add to the interest and enjoyment of the day; and it is astonishing what a great attraction an observatory hive of living bees is to the general public. I may safely say not surpassed by the finest dish of fruit or flowers. In many prize schedules of small provincial shows it is customary to offer a trifling prize for honey, rightly considered a floral production; and if the committees would extend their honey prizes and open them to all comers I feel sure they would make a move in the right direction, and, with an exhibition of hives added, do much towards placing before their poorer neighbours a means of increasing the family income. At most of the shows I have mentioned practical demonstrations of driving, artificial swarming, transferring, &c., have been given, the spectators being fenced off from the flying bees by a gauze screen; but in some instances, so eager has been the curiosity of the crowd, that the

slight barrier has been demolished without any apparent penalty being enforced by the disturbed bees. Indeed at Berkhamsted, where I was the manipulator, we had no screen whatever. I drove the bees from their full hive to an empty one and afterwards returned them, closely surrounded on all sides by an eager and curious crowd, some of whom readily became my assistants unprotected by either veil or gloves, and I heard no single complaint of a sting being used. After my exposition an old man remarked to me, "Well, sir, I have taken up bees many years with brimstone, but after what you have shown us I hope to try next time to do as you have done to-day."

Country gentlemen who have learnt to handle bees fearlessly are now numerous and widely scattered. They would do much in the cause of bee culture if they would inaugurate bee shows, in conjunction with flower shows or not, in their various localities; and if the want of funds stands in the way, then let a small charge for the bees be made, and it will be found readily met. At Ealing Horticultural Show this season no provision had been made for bees, but I placed an observatory hive on the table, and such was the interest excited that before the day closed the Committee resolved to have a bee show next year as an auxiliary to that of the fruit and flowers.—JOHN HUNTER, *Eaton Rise, Ealing.*

OUR LETTER BOX.

ADDRESSES (A. B. C.).—We do not know those which you ask for. Write to the Secretary of the show.

UNITING STOCKS (Anxious).—You have nothing to fear, as both the hives you name are in pretty good condition for the winter. Contract their doors, keep them warm and dry, and look forward to next year for a good return from them. The best way of uniting swarms is occasionally discussed in our columns.

REMARKS.

26th.—Grey early, but fine forenoon, and bright all day; rather less so at night.
27th.—Dense fog all the forenoon, clearing off about 1 P.M.; very pleasant afternoon and evening.
28th.—Very fine all day, though slightly cloudy about 1 P.M.
29th.—Very bright and fine all day.
30th.—Bright, fine, and fresh all day.
1st.—Another bright autumnal day.
2nd.—Hazy at 9 A.M., but soon followed by bright sunshine all day.
Fine autumnal week. Slight fogs in morning and evening, but not a drop of rain.—G. J. SYMONS.

COVENT GARDEN MARKET.—OCTOBER 3.

THERE is scarcely anything of importance to quote this week, the supply of goods being much the same as previously, and trade quiet.

From observations taken near London during forty-three years, the average day temperature of the week is 58.3°; and its night temperature 41.0°.

INSIDE VERSUS OUTSIDE VINE BORDERS.

NEARLY all Grape growers of experience agree that Vines succeed better with their roots in an outside border than under glass. At first this might appear singular, because Vines are generally understood to do much better under artificial treatment in this country than in a natural state, and certainly their roots are growing naturally when running unrestricted in the open ground. Why this difference should exist is an interesting

subject, and after considerable experience and thought on the matter I am convinced it is produced by a very plain cause. We will go no further than this season for a comparison between the two. Look at Vines now with their roots wholly inside and the fruit hanging on the rods. With the idea of improving the flavour of this fruit the border is kept nearly dust-dry. Many of the leaves are changing colour, but not the colour of slow maturity; they appear rather as if shrivelled and scorched. Can this be otherwise than injurious to the future well-being of the Vines? Take other Vines with their roots all outside: from the great amount of rain we have had the border cannot be otherwise than wet—actually saturated, and the roots plump, the foliage green, and the fruit swelled to its fullest extent. This is part of the difference between the outside and inside. Some might say the fruit must be deficient in flavour with the roots in a moist border. It is nothing of the sort; quite the reverse. I have tasted Grapes—all kinds of Grapes—over and over again from Vines with their roots outside, and in flavour they were in every respect equal, and in juiciness far superior to the half-raisin-like fruit of the inside Vines.

But it is not a small matter of good or bad flavour for one year that is of most importance. This is the chief question, Will the Vines succeed much better through all their existence with their roots outside than in? They will, or all my observations, and many others' besides mine, are wrong. Vines with their roots outside I have always observed as starting stronger into growth, remaining more healthy through the season, swelling their fruit better, colouring it better, and keeping it better from shrivelling, shanking, and other diseases than Vines having their roots inside.

I once saw a great many vineries planted in succession—two or three one year, the same number next, and so on. The vineries were made so that the whole of the Vines had to be planted inside, but at the same time they could reach the outside border after a year or two. During the time the roots were inside the Vines did not make the most satisfactory progress, and the first and second crops shanked; but after this, and as soon as the roots were plentiful in the outside border, the Vines made a more vigorous start than ever they had done, and since then shanking has been unknown, and the Vines have always been much freer from insects than formerly. Now, nothing whatever was changed inside from what it originally was, the only difference being the roots out-

side, and, curious to say, the soil and other ingredients in the outside border were the same in every respect to that inside. All the difference was the outside border was never covered, but was always moist, especially in the winter time, while the inside one was dry as being supplied with no water for five or six months in autumn and winter could make it. This would certainly lead one to suppose that Vines do better with their roots outside than in, because the outside Vines are never dry at the root. This I believe is the whole secret; and I believe further, that it is one of the greatest mistakes that can be made to let Vines become so dry at the root at any time as many think is advantageous to them. No young roots are more easily injured than Vine roots. I have seen them quite fresh at the outside of the ball of a Vine grown in a pot in the morning, and after the leaves have flagged for want of water during the day every one of the young fibres were dead at night. When the leaves are off the Vines of course it cannot be seen how the foliage might go down for want of water; but the roots will perish as quickly when the leaves are off as on, and there cannot be the slightest doubt that many young roots die in inside borders in the winter time: hence their deficiency of root-action, shanking, and other evils the following season.

Vine-border-making is included in the work to be done with us this winter. The outside will receive our very best attention, but the inside we will have nothing to do with.—A KITCHEN GARDENER.

THE ROSE ELECTION.—No. 2.

It is rather interesting to note the position of some of the Roses which have attained their place in the forty-eight, not by superlative merits, but I imagine rather by all-round good qualities. Such I consider those to be that have comparatively few first or even second-class votes, and yet find a place amongst the *élite* of the selected forty-eight—notably No. 13, Mdle. Marie Rady, has only five first-class votes; Edouard Morren, again, No. 19, has but two. It cannot, in fact, be said that there are a dozen Roses so generally excellent as to obtain two-thirds of the first-class votes. This is rather extraordinary, neither do I think it would have been suspected beforehand. Let us see.

Marie Baumann	} 43	Charles Lefebvre	} 42
Alfred Colomb.		La France	
Maréchal Niel and Baronne de Rothschild..		41	

Then comes even thus early a great drop, François Michelin obtaining only thirty-seven, a number that must increase if its constitution prove good, the only point I think of doubt about this great acquisition to our Rose list; then Marquise de Castellane rises above Etienne Levet, scoring twenty-four votes to the latter's twenty-three. In previous elections I have been surprised at this Rose being invariably placed over François Michelin, as in form it is so very inferior, at least as it comes with me, though I grant exceptional blooms are of rare beauty in other characteristics. Louis Van Houtte received

twenty votes, Duke of Edinburgh seventeen, Madame Victor Verdier fourteen. It is astonishing that in the first twelve Roses there should be a drop so large as this, the twelfth Rose failing to reach one-third the number of first-class votes. It may interest "WYLD SAVAGE" to note that, continuing this test, Catherine Mermet becomes fifteenth with nine votes, Dr. Andry and Eugénie Verdier tying at one vote above her; but to look down the second twelve tried by this test it would seem that our first-class Roses are but few. Contrasted with this some of the newer Roses, especially those of 1875, have proportionately a far larger number of first-class votes, though, probably from want of thorough trial, they have only a small number in the grand total; notably amongst these we may mention Mons. E. Y. Teas with four first-class votes, Comtesse de Serenyi with five, Duchesse de Vallombrosa with five first-class votes out of a total of fifteen; indeed it would seem very probable that these Roses with another season would stand considerably higher.

I now add the greater number of the amateur lists, and propose when completing this portion to make a few remarks on Roses that greatly resemble each other—a subject that has already excited some comment and that the list of one of our most esteemed rosarians brings again prominently forward.—JOSEPH HINTON, *Warminster*.

VOTES IN ELECTION.

In the following returns the Roses are placed in the order of merit—in twelve, twenty-four, and forty-eight varieties:—

R. N. G. BAKER, Esq., *Heavitree, Exeter*.

GREEN VEGETATION ON WALLS.

WHITWASHED walls in vineries and other glass structures are very apt to become green from the constant syringing required to keep these houses cool and moist. For many years I could not overcome this difficulty. An old mason seeing the wall of a large vinery covered with green matter offered to cure it. He took a pint of common vitriol (sulphuric acid)

and mixed it in a pail of water, and with this brushed the wall. This was done with the idea of destroying the germs or seeds of this green mould. A few days after this the wall was whitewashed, the limewash combining with the sulphuric acid on the wall forming sulphate of lime. This operation took place five years and a half ago; the wall has not been discoloured nor whitewashed since.—OBSERVER.

CUCUMBERS.

HAVING resolved in my mind that our requirements could be met by two kinds—one for everyday use, a cut-and-come-again sort about 12 inches in length, short neck, symmetrical in shape, swelling quickly, good flavoured, free-bearing, and hardy constitution; the other having the good properties of the former but twice the length—I had fixed upon Munro's Duke of Edinburgh as the everyday kind, and Tender-and-True for beauty and good quality. Experience had shown them to be all that could be desired. Why give space to others which would take up room that might, as hardy fruits were likely to be scarce, be more profitably employed with Melons? Ruminating—seeing space not wanted for Cucumbers devoted to Melons—I was interrupted by receiving seed of a new Cucumber—viz., Montrose Seedling, from Colonel Taylor, Montrose, Weston Park, Bath, described as a cross between Sion House and Lord Kenyon's Freebearer, pedigree sufficient to convince it must be an everyday kind; and seeds of a new frame Cucumber were also received from Messrs. Suttons, Reading, simply marked "a new frame Cucumber." Why not pit these against the favourites; give them a chance, devote a frame to each? It only represented so many Melons less per light for every one set apart for Cucumbers, and why not crop the Melon plants more heavily? An extra fruit per plant would balance the loss. Who knew but what I might have winners in the untied? Of course, as Burns puts it—

"The best-laid schemes o' mice and men gang aft aglee,"

the space might be wasted, the Cucumbers would probably disappoint, as new things often do; and how well the Melons would be appreciated, particularly when the luscious Peach is wanting! Only by trial could a satisfactory conclusion be arrived at, and if the opportunity were let slip it might never recur.

Never have I let an opportunity pass of making an experiment when it would not interfere with the supply. Experiment is the key of information. More is to be gained by experiment than a theoretical knowledge of all the ologies. There is no denying the fact that experiments, if to be of use, must be conducted upon such a scale as to show a correct issue. A plant in comparison with a dozen stands no chance, for there is great diversity in subjects of the same kind. The experiment must be comparative—an equal number of plants under the same climatic and cultural conditions, with the same amount of space. Give a plant twice the space of another equally requiring that essential and there is no comparing the doings of the two, as justice is only done to one, which in a great measure accounts for the great doings of new subjects. Seed is scarce, and they are thinly cast upon the ground. The plants do wonderfully well, but when subjected to ordinary culture, that of the standard older kinds, their doings are not nearly so satisfactory as in the year of trial. They come out at first all right, but after a few years it is very uncertain what kind it will have degenerated into; of course it is all due to the difficulty in keeping the stock pure. They have been so often and long crossed that they degenerate or sport. I am fully acquainted with the great difficulty of procuring seeds of some kinds true to name, but that it is due to degeneracy is only an excuse for negligence in the selection of stock. I have this year Early Longpod Bean for Seville Longpod, a Pea about 2 feet high for G. F. Wilson, a short white spine Cucumber for Munro's Duke of Edinburgh, and I am to accept them as due to degeneration. Fortunately some seed of the true stocks pronounce very decidedly against such reasoning, and we must accept the fact, unpalatable as it may be, that there had been a substitution—a very different word from degeneration, and having a decidedly contrary meaning.

I will endeavour to describe Montrose Seedling Cucumber. Plant hardy, succeeding in a cold frame with a slight warmth at commencement from a bed of leaves and a little old litter to hold the leaves together; foliage moderate, the leaves not large, the bine not strong; fruit at almost every joint—five, six, or more joints consecutively, not a great number of fruit

at a joint, which is no advantage, as one takes the lead and the others are mostly crooked and otherwise ill-shapen from irregularity of swelling, this having the character of swelling quickly, regularly, and certainly. Fruit deep green, 12 to 15 inches in length, skin smooth or very few spines, very symmetrical in shape, very short neck, flower borne well at the nose, altogether a handsome fruit and good; core or seed space small, no seeds found in any fruit cut, the flesh well flavoured, free from bitterness or any unpleasant taste. Very prolific, my two plants in a two-light frame giving sixty fruits in a month, and though the plants have been fruiting four months none of the fruit have shown a disposition to "knob" at the end, which is not unusual with most kinds late in the season. Its Sion House type is very marked, bearing some resemblance to Munro's Duke of Edinburgh, having a hardy constitution. It will displace those I have hitherto grown for "everyday" use.

"New Frame" Cucumber is a rather strong grower, but not so strong as Marquis of Lorne; foliage rather large, good constitution, succeeding in a cold frame with a slight warmth from leaves held together in a bed by stale long litter. Fruit 20 to 24 inches in length, neck short—scarcely any—remarkably regular in thickness from neck to nose, the flower well carried, skin deep green covered with "blue" bloom, very beautiful in symmetry and bloom; spines white, sparingly but regularly disposed, render it very attractive. The fruit had little core, no seed found in any, and capital flavour. It swells freely, fruits freely, and certainly is the handsomest fruit I have seen. I only regret that I have not been able to secure any fruit at all like seedling as yet. If only it would "knob" I should feel satisfied, for I have no object in growing these things other than to possess myself of the best kinds. I have tried my hand at crossing Cucumbers, but I get nothing for my pains except disappointment.

I do not know whether it has been noticed before or not—viz., that new kinds have at first, for two or three seasons, better constitutions than they afterwards exhibit. Can it be due to the influence of foreign pollen—fresh blood giving increased vigour? In-and-in breeding is well known as a source of weakness if not barrenness in cattle, why not in plants?—G. ABBEY.

BEDDING GERANIUMS AT CHILWELL.

THE season of 1877 will long be remembered in the annals of flower gardening as a most unpropitious one. The perpetual downpour of rain accompanied with extreme cold has told considerably against the beauty of the flower garden. Where *Alternantheras* will succeed carpet bedding has been in the ascendancy this season, but in many places they have not moved since they were bedded-out in June, and since the middle of August they have "grown small by degrees and miserably less;" and the Geraniums and other half-hardy blooming plants have been no improvement on the *Alternantheras*, for in many places they have presented a woe-begone appearance. However, in some favoured spots they have behaved themselves differently, and especially at Chilwell. The Geraniums in this nursery are standing monuments to Mr. Pearson's memory. His genial converse is missed now, but three sons who manage the business under the leading spirit (Mrs. Pearson) promise to walk in their father's footsteps, and to Mr. Charles Pearson I am particularly indebted for much courtesy. The Geraniums on the 19th of September were bright and beautiful, those under glass were more gorgeous than ever, and those in the open flower garden were in very good condition.

In the top garden nearest Mr. Pearson's house a number of circular beds were filled with Geraniums of one sort for trial. The very best in the garden was Mrs. Gregory, with beautiful rose-coloured flowers, large truss, dark foliage, stout footstalks, and an abundant bloomer; it appeared as if there had not been a drop of rain on it for weeks. The next in order of merit was Mary Pearson, a similar shade of colour to Mrs. Gregory; a free bloomer, fine flowers, the shape of the truss all that could be desired. These were sent out in 1876. Of the crimsons, the Rev. A. Atkinson stood pre-eminent, in colour a glowing crimson, the trusses fine; an improvement on Bayard, Mrs. Mellows, and Brutus. David Thomson, sent out last year, is much of the same shade of colour as the Rev. A. Atkinson, has immense trusses, very stiff footstalks, and the flowers well up above the foliage. In the lilac pink section the well-known Mrs. Turner was most beautiful. We

had always thought that the trusses of Mrs. Turner were too large for bedding purposes, and especially during a season remarkable for its rainfall; but however, there she was as bright as ever, clad in all her blushing beauty. Mrs. Turner was the best pink Geranium on the trial beds. Lady Byron, a beautiful soft pink with a light centre, is without a rival as a pot plant, but is not suitable for outdoor bedding. Colonel Wright of the rosy-red section appeared to stand the weather well; the trusses were large and well-shaped, the flowers very perfect. Ernest is very much of the colour of the Colonel, and quite as good in all respects. Charles Schwind, fine dark glowing crimson, with good habit, is the darkest Geranium yet sent out. S. Plimseell, purple crimson, was too much run to foliage, but the trusses were very fine. John Gibbons, scarlet, was the best bedder on the lawn last year, but this year is not quite so good. Rev. S. Hey, rosy red, was very dwarf, and an effective bedding variety. Mrs. Jacoby was very good as regards the quantity of bloom, but the colour, a salmon rose, was nearly all washed out of it. Mr. Pearson told us how good she had been in favourable seasons. Mrs. Paget, soft rose, was moderately good, but the fine satiny texture of the flowers is too delicate for this stormy weather. Among the Golden Tricolors Mrs. H. Walters and Rose Wood were specially noteworthy; and in the Silver-edged section Rosamond Wright was distinguishable for the purity of her leaf-markings.

Turning into the long Geranium house it was—as is always the case between the 1st of April and Christmas Day—a perfect blaze of flowers. We need not enter into detail respecting the merits of these plants for decorative purposes, for they have been described in these pages over and over again. We will, however, just mention a few of those sent out this season. Mrs. Levers, pink, with white eye, large flowers, and truss compact and good. Colonel Seely, scarlet flower, with white eye; the flowers are perfect in shape, and would come up in every point to the requirements of the florist. Gertrude, salmon colour, the individual flowers are more than 2 inches across; this is a noble flower. Mrs. Pearson and Lizzie Brooks, each with salmon scarlet flowers, very large, exquisitely good. Charles Schwind, very dark crimson, a splendid pot plant. Rebecca, rosy crimson, the trusses 7 inches across. There were many others all worthy of note and deserving a place in any collection, but these named are among the best. We observed thousands of seedlings in various stages of growth, and among those to be sent out next spring are some fine doubles of various shades of colour, quite a new feature from this nursery.—VISITOR.

VINE RENOVATION AT WIMBLEDON HOUSE.

VINES have of late years been, perhaps, the weak point of Sir Henry Peek's beautiful and well-appointed garden. The soil of the district is light, and is not what is known as of a "wearing" nature: hence the Vines which flourished well for a time eventually lost their vigour. Since Mr. Ollerhead has had the charge of the garden the Vines have been a source of much trouble to him: to a gardener so thorough as he is they could not be otherwise than disappointing. It is only recently, however, that he has been able to direct his attention to their renovation by a renewal of the borders and raising of the roots. As others may be contemplating the renovation of their Vines, and as this is the right period for the work being done, the plan adopted at Wimbledon may be usefully mentioned.

The Vines are perhaps thirty years old. They are planted inside, the roots having access also to outside borders. They are planted and trained about 4 feet apart, and have been pruned on the spur system.

Preparatory to the renewal of the borders, and as an important element in the restoration of the Vines, Mr. Ollerhead last year trained up two young canes from each Vine, selecting those which issued from the rods as near to the ground as possible. These were trained between the chief rods.

Such old Vines have old fireless roots—roots which do not always in the readiest manner emit young feeding spongioles even when fresh soil is provided: they would emit fresh roots probably more quickly from the rods if laid in the soil than from the old black roots. By the plan adopted by Mr. Ollerhead the Vines have an opportunity of doing this—in fact are doing it, for the Vines in one house were operated on in August, and the roots from the stems laid down then are now permeating the border. A free lateral growth has resulted, and the Vines are established for supporting their next crop. Other houses will be done at once before the leaves fall.

The plan is briefly as follows: The soil of the old border is taken out inside the house and fresh soil put in. The roots are raised and placed nearer the surface. They are, I think, notched at intervals; a portion of the stems are also notched and laid in the border. The Vine belonging to No. 1 rafter is laid in the soil and trained up No. 2, while that belonging to No. 2 is conducted underground and is trained up No. 1. Thus every Vine has a fresh rafter, the layered stems—quite 4 feet of each Vine—crossing each other underground between the rafters. Of the Vines so managed in August young roots are plentiful from the layered stems, especially from the young canes which had been encouraged to grow; the old stems have not yet emitted roots.

This mode of renovating Vines is well worthy of mention at the present time. The preparation of young canes, the notching of the stems and laying a portion of them in the soil, cannot fail to increase the root-action of the Vines to a very considerable extent, and is the almost sure and speedy forerunner of good Grapes as at Wimbledon.

The border inside the house is not made of the full width of the house, but 3 or 4 feet furthest from the Vines contains simply fermenting manure. Such manure placed in ainery at the time of starting the Vines is of great assistance to the breaking of the eyes, it also promotes healthy growth afterwards, adds gentle heat to the border, and as the manure decays forms a rich larder of food for the support of the Vines when the crop is swelling and ripening. Mr. Ollerhead's plan, I believe, is to remove the manure at the winter pruning, and with it the roots which have penetrated it, placing fresh manure and encouraging fresh roots yearly. If I am wrong in my assumption Mr. Ollerhead must oblige by correcting me. It is a somewhat bold course of treatment—a wholesale annual root-pruning, but which will no doubt answer its purpose admirably—as well, indeed, with Vines as with fruit trees in pots to which the practice is commonly and successfully applied.—J. W.

THE ROYAL GARDENS, HAMPTON COURT.

No more convincing proof of the increasing popularity of Hampton Court can be needed than to witness the many thousands of visitors who frequent these gardens daily. The noble avenues of Lime trees verging on the banks of a pleasant stream afford delightful shade from the fierce rays of a mid-summer sun, and lend a charm to the numerous flower beds for which they form a background.

Entering the gardens from the Palace front I found the long ribbon borders planted with Hemp; tall Abutilons, Cannas, Tobacco, Castor Oil, Solanums, and other subtropical plants forming a background, and so well do they answer the purpose required of them that in many places they completely shut out the wall behind them. In the front of them were Geraniums, and marginal lines of Golden Chickweed and *Cerastium tomentosum*. These borders are about half a mile in length. The walls behind are draped with Clematises, Honeysuckles, &c., which add to the beauty of these grounds at other seasons of the year. The flower beds have been very beautiful this year, and a brief outline of a few of the most pleasing may be acceptable. A bed planted with Miss Kingsbury, a very clear white variegated Geranium, intermixed with Viola Blue Perfection, surrounded with a double row of Iresine Herbstii, and margined with *Cerastium tomentosum*, was very effective. A charming bed planted in the "carpet" style also merits notice. Cables were formed with *Alternanthera paronychioides* lined with *Echeveria retusa* and a narrow belt of Golden Feather, filled in with *Sedum glaucum*, *Alternanthera*, and *Mesembryanthemum cordifolium variegatum*; the corner segments were planted with *Alternanthera amena*, and the whole edged with *Echeveria retusa*. This was altogether a very attractive bed. Happy Thought Geranium was here doing well, and displayed its strange freak of vegetation to great advantage. It was edged with Coleuses and Golden Thyme, and the trio made a very good bed. Opposite the tennis court was perhaps the best arranged carpet bed in the gardens. It consisted principally of ovals, circles, and their segments, and was planted with *Kleinia repens*, *Alternantheras*, *Mesembryanthemums*, and margins of *Semprevivum californicum* and *Echeveria retusa*. Many other pleasing beds must be passed, but not two of the most showy. Their centres consisted of large blocks of *Pelargonium Bijou* and Viola Blue Perfection freely intermixed (Violas do well here); then a broad belt of Iresine Lindenii surrounded with the Golden Stellaria. Whether viewed from a distance or examined

closely the arrangement was equally striking. Among the best Geraniums employed here are Sir George Natchet, Lucius, St. George, Waltham Seedling, Mrs. Haliburton, Warrior, and Sybil. Robert Fish and Golden Harry Hiever are good for edgings. The gardens and grounds were in excellent order, reflecting great credit on the manager.—J. W. MOOREMAN.

FUMIGATING.

SCARCELY anything can be more important in the practice of plant cultivation than the timely destruction of noxious insects, or preferably their prevention. Soil, watering, structural conveniences are all rendered comparatively inert if insects are permitted to become established in the houses or on the plants. Those cultivators who have won honours at exhibitions and have established their fame as accomplished plant-growers for home decoration are those who have persistently waged a war of extermination against insect pests. Those writers, too, who convey instruction in plant culture find it necessary to reiterate the importance of insect prevention or destruction. There are various ways of subduing insects, but one of the most familiar and effectual is by fumigation. Clumsy makeshift contrivances are frequently adopted in the burning of tobacco or tobacco paper, and when such is the case the work is unpleasant, and is often deferred until much injury has been done to the plants. By way of making fumigating a pleasant occupation Mr. Tebb has produced a handy, simple, self-acting apparatus which has been figured in our advertising columns. This having proved acceptable a smaller fumigator for frames and individual plants has been produced by Mr. Tebb, which is shown in miniature in the accompanying figure. To retain the smoke the cloth simply requires to be tied round the stem of the tree. We have tried this little apparatus, and it answers admirably. It consumes the tobacco paper freely yet without flame, and when the draught (which can be regulated at will) is adjusted by the moveable slide no further attention is requisite during the process of fumigation. The fumigators are made of various sizes, and are cleanly, cheap, and durable.

Fig. 55.
Tebb's Fumigator.

GRAPES CRACKING.

IN your impression of October 4th W. Harris seems puzzled with the vexed question, "What causes Grapes cracking?" I have not come forward to clear-up this mystery, but I suggest a little matter which, if not overlooked in his practice, is at least not mentioned in his remarks—namely, the state of the atmosphere.

Our friend asks, "Why should one sort crack more than another?" Some Grapes have thin skins, others thick, and, of course, the former must be more apt to yield to surrounding circumstances than their more leathery-skinned neighbours.

After describing his two unsuccessful attempts at growing Madresfield Court Grape without cracking he says, "Certainly everything was done to lessen the flow of sap to the berries, &c." Was he equally careful to facilitate the flow of sap from the berries? Was he sure the atmosphere was not too moist?

I am quite of opinion, though others may think differently, that the amount of moisture in the atmosphere of a house has more to do with the cracking of Grapes than either the amount of water supplied to the roots or the amount of foliage developed on the Vine. I have under my charge a house in the centre of which there is a pit once used for Pines, but now filled with ashes for the purpose of standing Ferns on. In this house there is growing together Muscat of Alexandria, Mrs. Pince, Black Hamburg, and Foster's White Seedling. I found that the latter variety cracked very much, but instead of cutting the shoots half through to cure it I took every plant out of the house as soon as the Hamburgs began to colour, and have done the same thing every year since, and have now no cracked berries, not even in this remarkably dull, sunless season, and in a locality, too, where about 14 inches of rain has fallen from the beginning of June to the end of Septem-

ber, the borders being all outside. Most men who have had much to do with Vines are familiar with what takes place on the leaves of Vines when the atmosphere is overcharged with moisture and indifferently ventilated, and I do not see any reason why berries with thin skins should not crack if the house is not moderately dry and well ventilated.—R. INGLIS.

RED-BERRIED SHRUB—ROSE MILDEW.

I CANNOT remember all the sorrows of the "CITY CLERK" and his questions, but I will answer all I can remember. The best plant for red berries is the Box-leaved Cotoneaster (*C. buxifolia*). It has beautiful white flowers in summer, and red coral berries in the autumn. It is a trailing shrub, very hardy, and will climb up a wall with support.

As regards mildew on his Roses, as soon as the "CITY CLERK" perceives it he must cut off the twig and burn it, as one tree will soon affect more. He must then give the plants abundant water at the roots, and also syringe the whole tree to wash off the resting spores. Sulphur and soot are valueless. A thunderstorm is the best cure for mildew and aphides.

As regards aphides, he must in early spring search for them, squeeze them, and syringe copiously afterwards, and continually. They will not then appear till September, when he must again squeeze and syringe. He will then be free in the meanwhile. I am never troubled out of doors with either of these plagues. When "D. Deal," was here, June 28th, I do not think he could find either mildew or aphides among 2500 Roses. The September aphides are egg-layers, and the spring aphides are viviparous.—W. F. RADCLIFFE.

ROYAL ROSES.

"I WAITED for the train at Coventry," as Mr. Tennyson says—at least at Slough, and suddenly bethought me of the royal county's Royal Nurseries and the truly royal Roses which issue from thence. Anyone who has an hour to spare either at Eton or Slough can hardly do better than spend it at Mr. Turner's interesting establishment. The gardens are of themselves most attractive. Magnificent Holly hedges afford shelter; and near the entrance a delightful little miniature Poplar avenue was still affording shade to Camellias coming on, and fall pot Briar Roses were recruiting for another campaign. Those giant Roses in pots so familiar at the spring shows were standing out in long lines enjoying the fresh air before entering on their London season. The plants are really prodigious. In nothing, I incline to think, are the triumphs of gardening science more manifest than in those wonderful Rose bushes which are now produced under glass. But my inquiry as usual was for the bed of seedling Roses. Under the guidance of Mr. Gater, the intelligent and experienced foreman of the Rose department, I was speedily introduced to all that was interesting. There is a time for everything, and I hold nothing in its way more enjoyable than a Rose chat amongst the Roses with one who understands them and makes his superintendence a labour of love. As I believe many others enjoy this also I have taken the trouble from time to time to put on record such gossip.

I spoke of the Rose seedling bed, but in fact there are many beds, Mr. Turner besides his own having become possessed of the stock of Mr. Laxton, to whom we are indebted for several excellent Roses. Indeed Mr. Laxton has sought after new Roses more scientifically than, as far as I am aware, any other grower. In almost all cases vast masses of Roses are grown together, and the bees or the wind in some way or other do the hybridising. Mr. Laxton, I believe, always fertilised the flowers himself. I saw a long narrow bed pretty full of his new seedlings. It will be strange if we have not something good from thence in the course of time. Among the Slough seedlings I saw several of considerable promise, though they must be good indeed to gain a place in the catalogue. People are hardly aware of the very severe ordeal which, in our English gardens at least, every new Rose has to go through. Even after it has been accepted and extensively budded, if it fail in form or fulness, however inviting the colour, it has little chance of ever being presented for a certificate. I saw one here, a red Rose of very fine shape and colour, which was only to be allowed to come out as a garden Rose. When, therefore, a new Rose is put forth as of promise by one of the great growers we may confidently consider it will be an acquisition. One such is to be shown by the Royal Nurseries next year, and to be in commerce the year after. Its

name is Harrison Weir. It is of the Xavier Olibo colour, with Charles Lefebvre wood and robustness—certainly something of very great promise. I saw many Briar stocks of it, but only one imperfect bloom. Thence we passed on to seedlings already out, notably Mrs. Baker, who was in great force, and, as might be expected, abundance—a very lovely Rose, such as the very charming lady to whom it is dedicated may certainly view with acceptance and complacency.

There were still many excellent Roses in flower. Mr. Gater said they had three seasons—that of the cut-backs, of the Manettis, and then of the maidens. At present all three seem uniting to form a fourth. Mons. E. Y. Teas was there, his character rising every season. Duchesse de Vallombrosa, an improved Capitaine Christy; Jean Liabaud, an improved Mons. Boncenne; Madame Prosper Langier and Duc de Montpensier, both spoken of highly. Souvenir de Spa, which I admired at Hailsham last year but have not seen since, was here very fine; and last but not least charming Comtesse de Serenyt, with its smooth, ivory-like, round, light pink bloom and of perfect habit. There were the usual acres of budded Briars most sturdily robust, and having at this time their cotton wrapping taken off from them. Thus I concluded a busy but most interesting hour.—A. C.

FLOWER GARDENING IN 1826.

It is fifty-one years since I began the gentle art of gardening, and I find from dire experience that there is more of what may be called glory than backsheesh connected with it. I began in the gardens of Admiral Sir J. Hope at Carriden, Linlithgowshire, and there was a very good flower garden there of fully an acre very well laid out, partly in grass and the rest a Box-wood design and herbaceous plants. The only bedding-out plant was *Senecio elegans*; one bed of it used to be planted, and very pretty it was; it was kept over from cuttings every season. I took a deep interest in the hardy plants; there was always something coming into bloom. I had the honour of serving three Earls and one Baronet for twenty-six years as head gardener and forester, and I stuck to the old hardy plants; but many beautiful varieties are grown now that were not to be seen in my early days, thanks to the enterprise of such firms as Backhouse, Ware, Parker, &c.

It was about the year 1841 when *Verbena Tweediana* and *Tweediana grandiflora* were introduced, and then the bedding-out began in a small way, but increased by degrees, till in many instances it fairly swamped the old herbaceous plants. Yet when the mania for bedding-out became so colossal I often thought that there would be a re-action, and I have advocated this for many years, and will while I can wield the pen. I know full well from my own experience and that of many of the very best gardeners in Scotland that bedding-out on such a large scale is a bore, and though attended with a large outlay for glass structures, men, and plants, that it seldom gives the amount of pleasure they were led to expect. What with drought, too much rain, and a want of sun, there is always something that is not up to the mark. If only one sort of colour dies, or partially so, the harmony of the parterre has vanished, and instead of its affording pleasure either to the gentry or the gardener, it is the very reverse. But even when the weather is so nicely balanced that everything is in order, only think of the expense of propagating the thousands of bedding plants, watering, planting out, pegging down, and staking up so many plants. If it were all counted up and shown to a lady or gentleman, I almost think I hear them saying, "I had no idea that there was so much spent for that which has given me so little pleasure, and think it will be necessary to turn a new leaf and see if the backsheesh cannot be turned to better account."

But what is to be done? Are we to fall back upon the old-fashioned herbaceous borders, and discard all the beautiful flowers that adorn our flower gardens and which add to the enjoyment of one's abode during the summer? Certainly I will be the first to say No to such a proposition. I have no more idea of bedding-out being abolished entirely than that I would believe that Sir Robert Peel's free-trade measures would be repealed, or that slavery, that accursed thing, would be again the order of the day.

I am quite sure that the gentry had more pleasure in their flower gardens even during the time there were nothing but shrubs and hardy flowers of all sorts than with the bedding-out stuff. I always had much pleasure in looking at a collection of Roses, Pinks, Carnations, Dahlias, &c., and in seeing

beautiful shrubs; there is always something new to be seen amongst them. But can the same tale be told about Verbenas, Geraniums, Calceolarias, &c.? Not at all, when they begin to bloom about the end of June, so as to have any show; they are the same day after day till the rain and cold in September destroys them. To my way of thinking they become insipid, and I only wonder how gardeners of otherwise good taste should care about such heavy monotonous masses. It is rare where the hobby of bedding-out is carried on so largely that everything else receives the attention it requires. About three years ago I went all the way to Lamport Hall to see that celebrated miniature rockery erected by Sir Charles Isham, and it certainly took me by surprise, and all done by the worthy Baronet's own hands during a period of nearly thirty years, and it far surpasses anything I ever saw; and next to it is Hoole House near Chester, but they are quite different. I saw Chatsworth, also Eaton Hall and Alnwick Castle, when on my tour to merry England. The beauties of Chatsworth, as the house and its surroundings, surpassed anything I ever saw, but Lamport Hall and Hoole House took me far more by surprise than any of the places I visited. I was much surprised and pleased this season with a place near Falkirk, Mayfield, belonging to Provost Russell. The evergreen and deciduous trees and shrubs were worth looking at, and then they are in beauty every day in the year, and the heights and colours may be so arranged as to give an artistic appearance to the scene. This seems to me far better than to see beds of bare soil "decorating" the lawn for nearly eight months in the year. Fine shrubs and trees, some few of the best bedding plants, and some spring and autumn-flowering plants, should be employed in due proportions, and I believe more pleasure and far less expense would result than by indulging in the modern system of garden decoration.—J. ADDISON, *Ormiston, Edinburgh.*

THE INFLUENCE OF SCION UPON STOCK

AND *vice versa* IN THE CASE OF THE VINE.

For a considerable number of years we have experimented with a view to prove the influence which certain Vines, as stock, produced on others when grafted on them, as well as the influence which one variety as a graft exerted on others as stocks. So far the results in some cases have been instructive, while in others they have been both instructive and most interesting. In grafting Gros Guillaume on the Muscat and not allowing the stock to make any growth, not even to develop a single leaf, the result was bunches somewhat more compact than the general run of Gros Guillaume bunches, more regular and larger-sized berries, and a colour exceeding in density any other Grape except the best-finished examples of Black Alicante. This variety, grafted on the Muscat and allowed to develop itself in the proportion of one to two rods of the Muscat on which it is grafted, has been very much increased in fruitfulness, and bears freely on the short-spur system of pruning. The shape of the bunch has, however, been entirely changed; the large shoulders characteristic of Gros Guillaume when well grown being wanting, the bunches having assumed a long tapering shape. The colour of the berries has not been nearly so dense—in fact they have been more of a grizzly colour, some berries colouring to nearly black on one side and grizzly on the other. The flavour has been appreciably improved, and the wood of the Vine ripens very rapidly and perfectly. On the other hand, the effect of one strong limb of Gros Guillaume on the two limbs of the Muscat is to deteriorate them, as well as to influence the character of the foliage considerably. As compared with other Muscats on which no other Grape has been grafted the limbs are weak, there being a tendency to shank in the bunches, and the foliage goes off early in the season with streaks of straw colour, much the same as Gros Guillaume goes off streaked with claret and crimson. The two Muscat limbs are also much more subject to scorching from intense sunshine than are the Vines entirely Muscat. These effects are distinctly realised and are very conspicuous at the present moment, an entire Muscat being beautifully green in foliage, and the Vine next to it with two Muscat rods and one of Gros Guillaume, with the Muscat portion of the foliage going off into straw-coloured streaks, like the Gros Guillaume; the fact being that the latter is deteriorating the character of the Muscat, while the Muscat stock and limbs are exerting a most marked influence on the Gros Guillaume.

Gros Guillaume grafted on the Black Hamburg comes very fine in berry and colour for about three years, after which it

deteriorates, becoming less fruitful and much smaller in bunch and berry. On one Black Hamburg grafted with Gros Guillaume we have allowed a spur of the Black Hamburg to grow on each side of the stock, about 6 or 8 inches below the union of the stock and scion. This was allowed in order to see the effect of a large spread of Gros Guillaume foliage on the small amount of Black Hamburg stock growth. Last year, as it happened, there were two bunches on the Black Hamburg spurs, and there was no appreciable effect on the fruit, but the leaves assumed the shape of those of the Gros Guillaume, and went off in autumn with exactly the same crimson colouring of that variety, while no other Hamburg foliage in the same house did so. This season there is just one bunch on the Hamburg spurs (they having apparently become less fruitful); but that bunch, although hanging over the hot-water pipes, has just, like those of Gros Guillaume on the same Vine, begun to colour, while the Hamburg bunches round about it are black. The berries are also much less in size than the other Hamburgs. The foliage on the two portions of the stock are this year again much more cut and pointed, and will no doubt change, like those on the main limb of Gros Guillaume, into crimson as they ripen.

In the case of Muscat Hamburg it has been found that, grafted on Black Hamburg and the stock and scion allowed to develop in nearly equal proportions, the bunches set better, form more compactly, colour better, and are less subject to shank than when it is grafted on the same stock and no growth allowed on the stock; the result in the latter case being large-framed bunches, with more stoneless and shanked berries.

Duke of Buccleuch on a Muscat stock, with also a limb of Gros Guillaume, does not succeed well at all. The berries shank very much. In fact, the fellow scion robs and cripples it. On the Black Hamburg the Duke does well, with the stock allowed to develop itself in about equal proportions; but from an eight-years experience of this Grape we conclude that it does best on the Muscat stock, the Vines being allowed to grow in equal proportions. The Vines on which it was thus grown were, however, destroyed. This Vine does very well on its own roots when properly established.

The Grizzly Frontignan has done best on the Muscat stock, the latter being also allowed to make growth in about equal proportion.

Trebbiano grafted on Muscat, and grown in proportion of one rod to two of the Muscat, does better than on its own roots; but from its very robust habit it has proved injurious to the Muscat.

From our experience we conclude that any Grape grafted on a given stock derives very little, if any, benefit or harm from the stock after a very few years, if the stock is not also allowed to make growth.—(*The Gardener.*)

A USEFUL PEAR.

A PYRAMID tree of Beurré Goubault in my garden, about 12 feet high and 6 through, regularly bears year after year from 150 to 200 fruit, and I now send you a portion of a branch to show that in this unfavourable season it has maintained its fruitful character. Though not to be compared with the best autumn Pears, such as Beurré Superfin, Louise Bonne of Jersey, Comte de Lamy, Thompson's, and General Todtleben, it has a fine flavour and the great merit of ripening gradually over a period of two months without going at the core, my single tree affording a constant supply from the middle of October to the middle of December, though in some seasons it comes in a week or two earlier or later; but this has been my experience with nearly all kinds of Pears. It is necessary to note that it generally remains quite green when fully ripe.—ESSEX.

[The branch received fully sustains the free-bearing character of this Pear, for on a length of a little more than a foot are eight excellent specimens.—Eds.]

THE POTATO DISEASE.

MR. ADDISON says that no one shall make him believe that the disease did not exist previously to 1846. He is quite right, for I have seen the disease in Potatoes in 1836. I do not write to please Mr. Addison, nor do I wish to contradict any other writer, but what I have seen I believe in.

Another writer says that no one can tell the cause of the disease, and that the diseased Potatoes infest the land. My

reply to this is, I have grown Potatoes on the same land for seven years and had no disease. I have tried all sorts of manure, and I find that with a good dressing of quick or gas lime Potatoes can be grown in the same land for a number of years. As for diseased Potatoes having anything to do with the next planting is out of question. Dress your land well in December or January with quick or gas lime, and you will have no disease. If anyone should have a doubt let them try one pole of ground with 2 cwt. of lime, and I shall be most happy to hear the result.—W. G.

PRIMULA VILLOSA NIVEA.

SOME confusion appears to exist as to the correct name of the charming *Primula* now figured. It is popularly called *Primula nivalis*, and is referred to under this name by Mr.

of charming flowers. Mr. Douglas grows this *Primula* well, and finds it worthy of his best care. Its cultivation is gradually increasing, as one of the most distinct and pleasing of the attractive family to which it belongs.

THE CLOUDED YELLOW BUTTERFLY

(*COLIAS EDUSA*.)

It is curiously illustrative of popular caprice that while the Colorado beetle, which has not yet settled here, has been puffed into astonishing notoriety by newspapers and periodicals, many interesting facts which immediately concern British entomology receive no mention. I have seen hardly any references beyond scientific journals to the abundance in which *Colias Edusa* has appeared in 1877, there being the unprecedented circumstance of a numerous flight of these

Fig. 56.—*PRIMULA VILLOSA NIVEA*.

Donn; the Dahurian *P. nivalis* has, however, purple flowers. It is known also as *P. nivea* (the Snowy *Primula*), and the name is appropriate, for the flowers of no *Primula* are more pure and chaste. The author of the "Botanical Magazine" considers it a variety of *P. villosa* on account of its essential resemblance to that species—its villous wedge-shaped leaves, toothed at the upper ovate part only and quite entire below, and by the funnel-shaped form of its flowers. It is one of the most attractive of small-growing *Primulas*, and when grown in pots or pans, and flowered under glass, as it should be, few dwarf plants during early spring are more noticeable in the greenhouse. It requires much the same cultural treatment as the *Auricula*, and at this period of the year requires attention to prevent it from damping; indeed nearly all the dwarf *Primulas* demand a little extra care now by providing them with suitable winter quarters. A shelf in a light well-ventilated house or the wooden stage of a cold frame are suitable for this tribe of plants during the winter months. When they show signs of growth in the spring a top-dressing of fresh enriched soil and more copious supplies of water aid in producing good trusses

butterflies in the spring as well as an autumn brood. Indeed, in some places they almost outnumbered the common Whites. Formerly scarce and then seemingly partial to the coast, *C. Edusa* has gradually become commoner, but this season has brought it out in unusual force; and as it feeds in the larva state on Clover and Lucerne, it might furnish a topic for alarmist paragraphs. There is, however, a probability that our very variable winters will always keep the species in some check.—J. R. S. C.

NOTES FROM CORNISH GARDENS.

TREGOTHNAN, THE SEAT OF VISCOUNT FALMOUTH.—No. 2.

THE mansion, a massive pile, was figured last week. The walk (fig. 57) leads from the lawn and forms a singularly appropriate approach to the house, passing as it does among lofty trees, fringed with a fine growth of *Rhododendrons*, a magnificent old Silver Fir standing out prominently, meeting the eye agreeably without obstructing the view. At the end of this walk, close by the house, are many *Camellias* wonderfully

fine, 12 and 14 feet in height and of a proportionate diameter, every one of them in admirable condition—a dense mass of foliage from the turf upwards. Never again shall I care for Camellias in pots, one glance at these glorious specimens bringing conviction to the mind that the roots must ramble freely in the soil, untrammelled by pots or tubs, to produce such vigorous growth. Surely the capacity of the Camellia for decorative purposes is not half so well understood as it ought to be. It will not answer so well in the open air in every part of the country as it does here, but it ought to be planted out in every conservatory bed, and it is undoubtedly the shrub of shrubs for winter gardens and crystal palaces. A meed of gratitude is due from horticulturists to the noble owner of Tregothnan for planting this exotic shrub so extensively, and affording such conclusive proof of its value and hardiness.

The principal or terrace front of the house commands a fine view down a valley having dense masses of timber on the right-hand slopes, not of formal aspect, but sweeping gently forward in rounded outlines down to the turf-clad slopes of the park on the left. In the distance there is a glimpse of the waters of the Fal winding picturesquely in among the trees, and beyond rise other wooded banks, the densely clustering tree tops marking the undulations of the slopes almost as if they were turf, so soft and pleasing is the effect. One turns from this pleasant scene with regret, for, most unfortunately, the terrace is not in harmony with it. Its boundary, a wall, running right across the valley, forms a stiff and uncompromising object for which nothing can atone, nor is there anything upon the terrace itself that is at all calculated to do so. The remedy is obvious: The wall facing the bottom of the valley should be removed and a wide flight of broad granite

Fig. 57.—TREGOTHNAN—VIEW IN THE GROUNDS.

steps introduced, with elaborate balustrades and vases for flowers; low tazzas, also, should be put upon the parapet of the remaining portions of the wall from each side of the steps to the ends of the terrace. The terrace itself is now occupied with circles of Box embroidery and spar of various colours, which might be dispensed with advantageously. In the centre there should be some object worthy of the position, and in keeping with the stately mansion with which it is inseparably connected. A group of statuary would, of course, be in excellent taste, or, if statuary were objected to, a raised flower bed, ascending in two or three tiers of stone or terra cotta, having a broad fringe of the dwarf *Rhododendron ferrugineum* round the lower tier, with no turf, but a bold encircling sweep of gravel or white spar, with turf beyond towards the ends of the terrace, where geometrical designs for flowers with curved, not angular outlines, would tell well. The central stone tiers should not be perpendicular and stiff, but should present a curved, flowing, and really ornamental front, and be so well proportioned and symmetrical as to render it a striking central ornament, pleasant to behold even when not gay with flowers. The broad fringe of *Rhododendrons* would add to its dignity as well as impart the requisite repose.

In contrast to the imperfections of the terrace the carriage court is unobjectionable, being in excellent proportion, with an agreeable margin of turf springing in semicircles from the

angles of the walls, and with an ample central expanse of gravel, altogether forming an adjunct to the buildings of the highest importance, imparting to them an indescribable air of completeness and dignity.

If an unusually critical tone has been indulged in it is because its subject is worthy of it. The gardens at Tregothnan are so beautiful that one longs to impart completeness to them by getting rid of the one or two blemishes indicated; by seeing more attention given to a due provision of shelter from high winds for the numerous trees requiring such shelter, and which are so worthy of it; and to the thinning and pruning of trees and shrubs so much required. The collection of shrubs is a fine one, but there are hundreds of magnificent specimens overcrowding each other so much that if prompt measures be not adopted the whole of them will be spoilt and the groups and borders become mere thickets, devoid of that individuality which is so charming, and without which even a wood becomes meaningless and tame.

Let it not be thought that these hints are intended to convey any reproach to Mr. Allen, whom I have much pleasure in naming as a painstaking gardener and worthy man, whose keeping of the gardens in such good order with the limited means at his disposal is highly creditable, but rather as pointing to needful improvements coming more within the province of a landscape gardener; and I may usefully conclude these notes

by calling general attention to the fact, that when a garden is planted for an immediate as well as a future effect due attention must be given subsequently to the thinning and re-arrangement of shrubs, and to such alterations as the development of growth invariably proves to be necessary—a work of such importance as may fairly be claimed to require mature experience, sound judgment, and cultivated taste.—EDWARD LUCKHURST.

STRAWBERRIES.

I THINK the authorities I mentioned are right in saying that the success of Strawberries in this country depends more upon the nature of the soil than the climate, but nevertheless I believe climate has something to do with it. La Constante does not succeed in some places in the south of England because the fruit is stewed on the plant by a too powerful sun. Myatt's Prolific would never be a first-rate Strawberry grown on any soil, and Nicholson's May Queen does not succeed in some places because the spring frosts are too severe; and according to Mr. Marsden Carolina Superba would not succeed in a rich loam, but requires a soil where red sand abounds. These instances might be multiplied.

If Mr. Luckhurst's ideas on this subject are right, and I cannot say that I agree with him, they are impracticable. It was easier for Mahomet to go to the mountain than for him to get the mountain to come to him—i.e., you may select Strawberries that will be likely to thrive in your present soil more readily than you can change the whole nature of it. Supposing you have a light soil on gravel, to change the whole of it, it would be necessary to go at least 5 feet deep; and if you kept the top foot of soil and carted away the rest, and brought back clay to go at the bottom and loam to go at the top of that, and had a mile or two to cart the materials, it would be a very expensive affair, and the alteration of a stiff clay to a loam would be nearly as bad. The mere addition of 3 or 4 inches of clay would not convert a light soil into a loam.—AMATEUR, Cirencester.

INTERNATIONAL POTATO SHOW.

No one not having seen the great exhibitions of Potatoes which have been held in previous years at the Alexandra Palace, and recently at the Westminster Aquarium, can appreciate their magnitude, character, and the interest which has been manifested in them by cultivators and visitors. Thousands of dishes of selected tubers carefully washed have an imposing appearance. Such shows afford evidence that the Potato has fanciers as ardent as has the Rose or any other product of our gardens. They represent also the magnitude of the trade which is established in the "noble tuber"—trade, too, of a decidedly "international" character, which has increased immensely during recent years, and which is not likely to collapse if commercial enterprise can maintain it in its present high position. A glance at the schedule of the Aquarium Show tells convincingly of the importance that is attached to Potatoes as a "fancy" crop by those who are intimately identified with the production and distribution of "show" varieties; for prizes—some of them extremely liberal—were provided by several firms, who thus seek to encourage the extended culture of the prince of root crops, and to promote the diffusion of improved varieties. It may be urged, indeed often is urged, that we have too many varieties already. Regarded strictly from an utilitarian point of view that may be true, as it is true of Peas, Broccolis, and other vegetables; yet new varieties of all these vegetables have caused a vastly increased interest to be manifested in the kitchen garden, and have stimulated high culture to an extent that would not have been indulged in if a few old varieties only had been adhered to. The present season has been one of the worst on record for Potato cultivators, on account of the prevalence of disease consequent on protracted wet and dull weather; yet it is highly probable that those who have been the most successful in producing sound crops are the "fanciers" who have given special attention to the selection of sorts and the best modes of cultivation. They have thus derived both pleasure and profit—the object, and a laudable one, of the promoters of the displays such as those referred to.

After we had left the Show last week certificates were awarded to the following varieties:—To the Rev. Mr. Peake for Vicar of Laleham, a red Paterson's Victoria; to Mr. McKinlay for McKinlay's Pride, a fine variety of the Ashleaved type; to Mr. Farguhar for Ice Cream, a handsome white kidney; to Messrs. Bliss & Sons for Trophy, a red variety of Snowflake; to Mr. Charles Turner for Early Bird, a beautiful kidney of the Ashleaved type; and to Mr. R. Dean for Radstock Beauty, a round exhibition variety of handsome shape, and for Bedford Prolific, a fine kidney of the shape of Jackson's Kidney, but quite dis-

tinged. In Messrs. Daniell's great collection we noticed a round variety named Masterpiece, certainly one of the most handsome Potatoes in the Exhibition, and which would doubtless have received a certificate had it been brought to the notice of the Judges with that object.

A few of the more handsome dishes and varieties suitable for exhibition purposes were the following:—*Kidneys*—Albion, Edgcott Seedling, International, Waterloo, Salmon Kidney, Sutton's Magnum Bonum, Lapstone, Yorkshire Hero, Ashtop Flake, Perfection, and Fenn's Bountiful (red), Veitch's Royal Ashleaf, and Myatt's Prolific. *Rounds*—Rector of Woodstock, Model, Bresee's Prolific, Climax, Fenn's Onwards, Taylor's Seedling, Porter's Excelsior, Red Emperor, Bresee's Peerless, Coldstream, Early Goodrich, and Carter's Main Crop (red).

VIOLETS EVERY MONTH IN THE YEAR.

IN your Journal of October 26th, 1876, Mr. Beachey gives directions for the culture of Violets and how to have them for six or seven months in the year, but says that everyone is not so advantageously situated as he is, Devonshire being the land of Violets.

I have had Violet plants in my garden as long as I can remember, which bloomed a month or two in the year as other peoples' do, and I thought that quite enough; but now I have Violets not only every month but every week in the year, and that without frames, pits, or forcing of any kind. The secret lies in my growing a particular kind of Violet, the name of which I do not know nor have I been able to find anyone who could tell me, so I send you a bunch, and perhaps you may be able to enlighten me on the subject.

About four years ago a friend of mine gave me a few plants, which he said he had had from a gentleman who had raised them from seed, and who told him they would bloom for nine months in the year. I divided and planted them in good soil, and in 1875 had Violets every month with the exception of June; in 1876 I had some every month, and this year I have hitherto had them every week, and shall doubtless continue gathering them to the end of the year.

I divide the plants in spring, cut runners off in summer, and keep them at all times free from weeds, and have often had Violets measuring more than an inch across, with stalks 7 inches long.—G. E. M.

[A valuable variety, resembling The Czar in size, colour, and perfume.—Eds.]

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

YUCCA ORCHIOIDES var. MAJOR. Nat. ord., Liliaceæ. Linn., Hexandria Monogynia.—Native of Southern United States. Flowers white. Hardy.—(Bot. Mag., t. 6316.)

ODONTOGLOSSUM CIRRHOSUM. Nat. ord., Orchidaceæ. Linn., Gynandria Monandria.—"This beautiful plant was discovered in the Ecuadorian Andes in the valley of Mindo, at an elevation of 6000 feet, by the late Col. Hall, who sent dried specimens to Sir W. Hooker that were imperfectly described by Dr. Lindley, and it has since been gathered in the same locality by his fellow explorer of the Andes, Dr. Jameson, and others. As a species its nearest allies are *O. Hallii* and *inter-purpureum*, both natives of the Andes, but it is abundantly distinct from these and all other species. Since its importation by the Messrs. Klaboch *O. cirrhosum* has flowered with many collectors, amongst the first of whom, I believe, is Sir Trevor Laurence, Bart., whose gardener, Mr. Spyers, informed Dr. Reichenbach that thirty flowers might be produced on a single panicle."—(Ibid., t. 6317.)

PITCAIRNIA FLAVESCENS. Nat. ord., Bromeliaceæ. Linn., Octandria Monogynia.—Native of Tropical America. Bloomed during April in the Kew Palm stove.—(Ibid., t. 6318.)

DENDROBIUM CRYSTALLINUM. Nat. ord., Orchidaceæ. Linn., Gynandria Monandria.—Flowers white, yellow, and pink. "It was discovered by Col. Benson, F.L.S., in Birma, and introduced by Messrs. Veitch, who first flowered it. The Royal Gardens are indebted to Messrs. Low for a fine specimen of it, which flowered freely, and the drawing was made from a plant in Mr. Ball's nursery in June, 1874."—(Ibid., t. 6319.)

ALLIUM UNIFOLIUM. Nat. ord., Liliaceæ. Linn., Hexandria Monogynia.—"This is one of several handsome new Alliums which have lately been discovered in California. It is found in the vicinity of Oakland, and about the bay of San Francisco. It was first named and described by Dr. Kellogg in 1861. It was afterwards found that name was not an appropriate one, the number of leaves not being a constant character. Of well-

known old-world types it is most like *Allium roseum* in the flowers, but its underground structure is quite unique in this very large genus so far as known, the bulbs being developed some distance from one another, and connected by a thread-like rhizome, like that of *Lilium canadense*. It flowered with Messrs. Backhouse & Son at Holgate near York in July, 1873."—(*Ibid.*, t. 6320.)

VILLA GARDENING—SHAFTESBURY PARK.

NEXT in importance to the means presented by the parks of London as affording wholesome exercise and sweet fresh air to the closely packed thousands of the colossal City is the examples they have provided of effective garden decoration, and the stimulus they have given to the cultivation of flowers by the artisan and industrial classes. The London parks as at present managed are great educational establishments, teaching—and this teaching is extensively followed—lessons which make homes more pleasant and their inmates more happy.

The spare hours of the industrial classes—the brain and muscle-working population—represent a great, an unrepresentably great power for good or evil. The time spent in those thousands—even millions—of resting hours cannot but exert a momentous influence on the lives and habits of the numerically greatest class in the community. The difference between those hours being spent worthily and unworthily is immense, incalculable. Too often time is wasted, and worse than wasted, not because what may be termed the abuse of life is indulged in from choice, but because of a lack of means for the time being employed in a more wholesome and salutary manner.

Villa gardening, however small the scale may be on which it is carried out, is an exercise which is commendable because it is at once pleasurable and beneficial. A garden of only a few square yards in extent affords the means for investing spare time profitably, and for exercising such good taste as is not uncommonly enveloped by fustian and corduroy.

If there are any who labour under the delusion that a considerable extent of ground is necessary, and untainted country air is indispensable for a garden to be worthy of the name, let them visit the locality contiguous to any of the London parks, and mayhap a useful lesson may be learnt on "economy," which is a popular term just now—economy in the arrangement of tiny plots, and an utilisation of the simplicities of the floral kingdom which are capable of contributing so effectively to home adornments.

One of the many examples of successful villa gardening carried out on a very small scale by a very great number is afforded by one of the suburban districts, the name of which is not unfamiliar to the great newspaper-reading public—namely, Shaftesbury Park. No more laudable undertaking was perhaps ever organised than that for the erection of small, complete, well-ventilated, and artistic "homes for the working classes." More than a thousand of such homes are occupied on this estate, and every home has a garden. Perhaps many of the little front plots do not exceed 12 feet by 6, and some are narrower than that, and the walled back gardens may not exceed 15 feet by 20, although several are larger; yet nearly all afford scope for the exercise of considerable taste, for many a little "back" contains its summer-house or greenhouse, while not a few of the frontages are ornamented in a most creditable manner. These floral decorations testify how much the gardens are appreciated and how greatly the homes are enjoyed by the occupants. In order to foster a taste for such salutary pursuits as gardening affords, encouragement has been wisely given by the liberal distribution of prizes for such examples of window and garden decoration as were considered worthy of recognition. These awards when carefully made by competent adjudicators afford a great stimulus to further efforts being made in the good work which they are intended to promote; and although for the present the excellent system may be in abeyance, it is to be hoped that it will eventually be resumed.

In the awarding of prizes of the nature referred to it is important that the capacities of each plot should be considered; also, as far as possible, attention should be paid to the matter of the raising and preserving of plants. Purchasing plants is easy to some, and little labour is needed to make a fine display for an occasion; but the credit attaching to such is certainly not greater than to those who have individually propagated and preserved the flowers, although the effect produced may not be quite so imposing. Not less important is it

that the backs as well as the fronts should be considered. A grand outside show, if at the expense of cleanliness and neatness behind the scenes, ought not to be unduly estimated. Tidiness and good order are as important as *Calceolarias* and *Geraniums*.

As may be expected in such a large community of miniature amateur gardens various styles of decoration are adopted. Some prefer the mixed style, and fill their garden with any plants they can obtain; others are partial to sweet-scented flowers, and indulge in *Carnations*, *Stocks*, *Sweet Peas*, and *Mignonette*. Some, again, have a fancy for evergreen shrubs, of which the most satisfactory for small town enclosures are *Rhododendrons*, *Aucubas*, and *Euonymuses*. *Veronica Blue Gem* appears to be a hardy shrub in the sheltered gardens of Shaftesbury Park, for several fine bushes have passed through at least one winter uninjured, and are now extremely attractive by their glossy foliage and profuse spikes of bright blue flowers. This *Veronica* should be grown in all gardens where out flowers are cherished. It only requires planting out in spring, potting in autumn, and protecting in frames or green-houses in districts where the frost is too severe for it to continue in the open ground. A few aspire to *Conifers*, which, however, do not thrive well in town gardens, yet *Thujas*, *Thujaes*, *Junipers*, and even *Retinosporas* are growing fairly well. Some little gardens are nearly filled with such shrubs as those mentioned, and are further carpeted with *Ivy*. Others contain no shrubs, but only flowers. Some of the residents "go in" for spring decoration, and "come out" strong with bulbs, *Pansies*, and that easily-grown and cheerful annual *Virginian Stock*. Others prefer summer flowers, and produce an "effect" with *Geraniums*, *Calceolarias*, *Golden Feather*, and *Lobellias*. Others again prefer plants of more elegant growth, and plant *Fuchsias* freely, and attractive they are in rather shaded positions. A few of advanced decorative proclivities adopt carpet bedding, having taken lessons, no doubt, in the adjoining park at Battersea. *Golden Feather* is, of course, the staple plant, but *Alternantheras* have come from somewhere; also *Leucophytos*, *Echeverias*, and even the now popular *Mentha Pulegium gibraltaria* may be seen. Some "go in" for autumn flowers, and in a space of 12 feet by 6, or less, devote their energies to *Chrysanthemums*. Others again have a weakness, or perhaps strongness, for *Roses*, but few are strong enough to make them succeed. *Roses* are not town plants. The best of all for a town garden is perhaps *Gloire de Dijon*.

Wall plants and climbers are in great favour. The most free grower of all is the *Virginian Creeper*, which forms festoons, and is permitted in some instances almost to cover the windows and darken the rooms, such is the love of "greenery." The smaller and closer-growing *Ampelopsis Veitchii* is finding its way up many a cottage wall, clinging to brickwork and even to metal spouting with determined tenacity; but it is only on sunny aspects and in rather dry soil that it assumes its brilliant autumnal garb. Here on a sunny wall is a *Ceanothus*, there a *Vine* growing freely and bearing well. Even *Fig trees* are not unknown, while *Passifloras* are luxuriant and beautiful. *Tropæolums* and *Convolvulus* are, as may be expected, very popular, and are only exceeded in numbers by one twiner, the common yet bright and useful *Scarlet Runner*; and *Clematises*, such as *C. Jackmanii*, are steadily finding their way into cottage gardens, and even such varieties as *Rubella* and *Star of India* are flowering freely in this floral suburb.

Window-box and sill decoration is one of the features of the "estate." In several instances it is done "to rights," if not to wrongs; for it is even whispered that cases are not wanting where inside comforts, even necessities, are sacrificed for outside show. Let us hope these are the whisperings of envy, and emanate from those whose fronts are not so attractive as they might be. Some of the window boxes, home-made of course, are artistically wrought, and afford evidence of skill, patience, and good taste on the part of the "manufacturers." Hanging baskets, too, and brackets for plants have their share in the domestic adornments.

Some of the miniature gardens are "laid out" chastely, others elaborately, and a few amusingly. Minton tiles, shells, white plaster, and black clinkers are all utilised. Several of the arrangements command admiration, a few provoking a smile, such as the erection of a "castle"—a miniature stronghold, correctly finished even to the cannon and ammunition, the whole being almost sufficient to fill a costermonger's barrow, or as a real Londoner proud of his vernacular would say, "barrer;" but such a mode of decoration is commendable, for it tells of the love of home.

Thus is villa gardening spreading, thus are workmen's homes made bright and cheerful and cherished by the ever-welcome smiles of flowers. Healthy homes and garden plots are the real antidotes to the many allurements which when indulged in leave behind them bitterness and misery. The garden lovers in these suburban homes work as earnestly and are as proud of their achievements as are those greater gardeners who honour themselves and the craft to which they belong by their trophies of skill at the great exhibitions. Let the gardeners from everywhere have the honours and rewards they so well merit; let the affluent enjoy in fullest excellence the produce of their gardens; but let also the humble earnest efforts of the thousands of those with kindred tastes have that meed of recognition which all gardeners are so ready to give, for by no class than gardeners and garden lovers is the truth of the old motto more fully admitted that "a touch of nature makes the whole world kin."—J. WRIGHT, *Ashbury Road*.

TERRA COTTA STOVE.

In answer to "J. C. B.," I have used a medium-sized terra cotta stove for my greenhouse for two winters, and it has effectually kept the frost out, the thermometer having been 50° inside when it was 12° outside. My conservatory is about 30 feet long. The drawbacks to the stove are smoke and dust, and the stove pipes supplied soon wear out. I grow Fuchsias, Camellias, Palms and Hyacinths principally. I should prefer a boiler for heating, but it is inconvenient to fix it. In buying a stove he must be careful that the rim at the top holds the sand properly, and he should get two buckets. I find charcoal the best fuel, but it is very expensive.—NEWTOWN.

OUR BORDER FLOWERS—LIPWORTS.

Among the many interesting plants that have been introduced to our shores from the North American Continent we look on *Cedronella cana* as an acquisition. The Lipworts are all destitute of any deleterious quality, and most of them are fragrant and aromatic. The *Cedronella* is so gifted, and those who like a strong aromatic perfume should be in possession of this useful and beautiful Lipwort. It is of graceful habit, from 1½ to 2 feet high, often forming a miniature pyramid, having whitish grey foliage and spikes of red flowers. It blooms during the summer and autumn months, but it is seldom seen in cultivation.

It is usually called a hardy herbaceous plant, but it is scarcely that in some districts. It must either be lifted in the autumn and protected through the winter, or cuttings may be struck in the autumn and kept in a cold dry pit plunged in ashes. They require care, being impatient of damp. They succeed well with the same treatment that is afforded *Pentstemons*. It may be increased by seed as well. If sown in heat in spring and carefully tended the seedlings may be had in bloom the same season. They are useful as pot plants for many purposes.

There are other kinds, as *Cedronella cordata*, *C. pallida*, and *C. mexicana*, but there is much sameness about them. The first and last named are most commonly met with: all require the same treatment.—VERITAS.

NOTES AND GLEANINGS.

THE visit to Carlisle of Mr. Cutler, the energetic Secretary of the GARDENERS' ROYAL BENEVOLENT INSTITUTION, was rewarded by contributions which will justify seven or eight additional pensions being granted next January.

—THE following new members were elected at the last meeting of the HORTICULTURAL CLUB:—Dr. Newington, Ticehurst; Messrs. E. G. Smeaton, Walham Green; T. Serle Jerrold, Avenue Road, Shepherd's Bush; and J. C. Fowler, Cumberland Lodge, Lewisham.

—WE are informed that Mr. HEAD, gardener to the late J. P. Gassiot, Esq., Clapham Common, has been appointed to succeed Mr. Legg as gardener to S. Ralli, Esq., at Cleveland House, Clapham Park. The public have, by the kindness of Mr. and Mrs. Ralli, derived both pleasure and instruction from this garden, which, all must hope, will be none the less enjoyable to its owners in the future than it has been in the past. Mr. Ralli's specimen plants which have been grown and successfully exhibited by the present gardener will, we believe, shortly be sold.

—A CORRESPONDENT writes complainingly that having

travelled some distance for the purpose of seeing the Potato Show at the Westminster Aquarium, he was not permitted to enter the Show at all, although he paid for admission into the building. He arrived at 3.30 and found visitors excluded from the Show, and barriers erected, which were not removed at 5 p.m., when he was compelled to leave the building to catch his train for returning home. We have heard other complaints of the same nature. With what object was the Show closed during the time specified?

—WE are informed that the only Potatoes used at the International Potato Dinner were SUTTON'S MAGNUM BONUM.

—As an attractive summer and autumn flowering ever-green plant for covering south walls *CEANOETHUS AZUREUS* has long been esteemed. Being a Mexican plant it is not sufficiently hardy for the northern districts of England, but in the south it succeeds well with no other protection than that afforded by the wall on which it is trained. One of the finest varieties of this plant that we have seen is *Gloire de Versailles*. The flowers are much finer and richer in colour than those of the species. For covering a south wall in a warm sunny position this *Ceanothus* merits especial notice. It is now flowering freely on the low south wall of the conservatory in the gardens at Wimbledon House, and its flowers are not only attractive when growing on the plant, but are very suitable for room decoration.

—GHENT AZALEAS, writes a Yorkshire gardener, are not only very effective when flowering in contrast with *Rhododendrons*, but their foliage afterwards contrasts remarkably well with the somewhat monotonous aspect of those shrubs. The fine glaucous blue tint of *Azalea pontica* is very conspicuous amongst the deep shining green of *Rhododendrons* during the summer months. Much may be done by foliage, but very much more by flowers. As thriving in the open spaces of *Rhododendron* beds may be instanced *Lilium*, which do not detract from the beauty of the foliage of the *Rhododendrons* in winter, nor interfere with their gorgeous display of bloom in early summer. Those having an eye for natural beauty may plant *Tropaeolum speciosum*, which, climbing over *Rhododendron* foliage, gives a blaze of scarlet in late summer. Will our correspondent tell us when and how to plant this *Tropaeolum* to insure its satisfactory growth?

—MESSRS. WEBB & SONS, nurserymen, Wordsley, Stourbridge, have sent us a schedule of prizes value nearly £300, including thirty silver cups, to be awarded at their ANNUAL ROOT SHOW on the 20th of November next, for specimen roots, Potatoes, root crops, cereals, &c. Entries for root crops (division 4) close on Tuesday, October 23rd, whilst those for specimen roots and cereals (divisions 1, 2, and 3) close on November 13th, and the latest day for receiving roots and cereals intended for competition is Thursday, November 15th.

—A BED of *PHALANOPSIS LUDEMANNIANA* nearly 60 feet in length by 4 feet in breadth, and numbering some two hundred fine flowering plants, may be seen, says the *Irish Farmers' Gazette*, at Lakelands, near Cork, the residence of W. Crawford, Esq., long noted for its fine collection of Orchids and other rare plants. About 4 feet in width of the wall of the East Indian house has been regularly lined off, wired, and padded with peat and sphagnum. In this perpendicular bed, 60 feet long, there are four parallel lines of *Phalanopsis*, large flowering plants, fifty plants in each line, and all in the rudest health.

—As the POTATO has a spreading root, and the tubers are nearly all developed upon the under surface of the fibres which run almost horizontally, it is considered by French Potato growers very injudicious to earth-up the plants, as this of necessity renders the roots more perpendicular.

—THERE are paints, washes, and heterogeneous steeps recommended for PRESERVING POSTS, but each are comparatively costly, and only partially successful. One great objection to the application of solutions externally rests on the fact that the sap being confined accelerates decomposition in the interior. Most foresters must have observed this. What I would recommend with fencing posts is, the materials, when felled, to be directly sawn into posts and stored under sheds thoroughly ventilated, where they will remain at least a year exposed to sun and wind. The neck, or part between wind and water, of each post should be slowly charred over a strong fire—slowly, because our principle means heating the timber thoroughly to the heart, so as to extract any moisture which may be still lodged at the centre, and hardening a crust on the surface of the posts. Afterwards, to prevent the posts absorb-

ing water, they should be well coated with coal tar, having its acid destroyed with fresh quicklime. The tar should be thoroughly boiled to evaporate all watery matter, and applied boiling hot. A large tank holding the posts set on end, and filled with the scalding tar from a boiler, answers the purpose very well. Of course the upper half of the posts can be painted when placed *in situ*. I am fully convinced coal tar, properly applied to thoroughly seasoned timber, is far more effectual in preserving posts than creosoting, poisoning, kyanising, or all the paraphernalia of iron prongs, sheet-iron wrappers, &c. One great recommendation in favour of the above process is that it requires no skilled labour, and the cost is a mere trifle. —(D. SYM SCOTT in *The Journal of Forestry*.)

— THE AMERICAN SHIPMENTS OF APPLES to Great Britain last year were upwards of 385,000 barrels, besides considerable quantities sent to France, Germany, and even Russia. A transatlantic contemporary observes that the opening of these markets to American fruit is an event of great importance, and establishes the business of Apple-growing on as sure a basis as that of the Wheat, Corn, or Cotton planter. It will be fortunate if the Apple crop in America is this year a full one, for it is rarely that such a scarcity of this useful fruit has been seen in British orchards.

NOTES ON VILLA AND SUBURBAN GARDENING.

FLOWER GARDENS are now beginning to look somewhat desolate, trees are shedding their summer clothing, and frosts have rendered Dahlias, Heliotropes, and other tender bedding plants useless; while in the kitchen garden department supplies of both Dwarf Kidney and Scarlet Runner Beans, also Vegetable Marrows, have been suddenly stopped. We have had frosts unusually early this autumn, and accompanied in the neighbourhood of London with dense fogs but no rain. Letters which have reached us from distant parts of the country tell us that frosty nights have been general, while the days have been bright and sunny, and thereby very suitable for ripening the wood of fruit trees, so necessary to withstand the severity of a sharp winter, and so conducive to the prospects of next year's fruitfulness.

The great business of propagating bedding plants for next season's summer's supply should by this time be nearly completed. Calceolaria cuttings should be inserted now in prepared cold frames. Ordinary Cucumber frames will do admirably, incorporating with the soil some sharp sand, and making all tolerably firm. Take-off small healthy young shoots either with or without a heel of the old wood, and insert firmly from 2 to 3 inches apart, and give them a good watering. Keep them close for a time, and as the cuttings show signs of becoming rooted air should be given on all favourable occasions, even to removing the lights entirely during warm days. In these unheated structures Calceolarias can be safely wintered if the protection of mats or other coverings are provided in severe weather. Pentstemons can be struck exactly in the same manner. These are beautiful border flowers. They produced a pleasing effect this year in Battersea Park, associated as they were with the free-flowering and attractive *Anemone japonica alba* (Honorine Jobert), dwarf Dahlias, &c.

BULBS.—Hyacinths first claim our attention. No flowering plants are more deservedly popular for room decoration, and none are more easy of culture. Hyacinths are said not to be so large as usual this year owing to unfavourable weather having prevailed in Holland during the growing period; but be this as it may, we desire the best possible results from those sent over, and whether grown in pots for the decoration of the conservatory, for the exhibition table, in glasses for decoration of rooms, or in beds and borders for the embellishment of the spring garden they must now receive immediate attention, and orders must be sent without delay to the respective dealers in bulbs for the supplies required. The subjoined list contains the best varieties that can be purchased, and includes cheap reliable older varieties which are still to be found in the winning collections at our metropolitan exhibitions.

Single Reds of all shades.—Duchess of Richmond, Emmeline, Gigantea, Madame Hodgson, Mrs. Beecher Stowe, Ornement de la Nature, Queen of Hyacinths, and Solferino. *Single White or Blue*.—Alba Maxima, Alba Superbissima, Baroness Van Tuyll, Grandeur à Merveille, Madame Van der Hoop, Mirandolina, Mont Blanc, and Queen of the Netherlands. *Single Blue*.—Argus, Baron Van Tuyll, Charles Dickens, Couronne de Celle, Grand Lilas, Leonidas, Marie, and Mimosa. The following are thirty exhibition varieties which have been separated from the above list on account of their high prices, and in some few cases the names in the foregoing list are repeated, thus showing that though cheap they cannot be dispensed with. *Single Reds* of all shades.—Cavaignac, *Fabiola, *Gigantea, Garibaldi, *Macaulay, Prince Albert Victor, Princess Clothilde, *Von Schiller, *Vuurbaak, and the indispensable semi-double red

*Koh-i-Noor. *Single Whites*.—*Alba Maxima, *Grandeur à Merveille, *La Grandeur, L'Innocence, Mirandolina, Miss Nightingale, *Mont Blanc, and Snowball. *Single Blues*.—Baron Van Tuyll, *Blondin, *General Havelock, *Grand Lilas, *King of the Blues, Lord Derby, Marie, Princess Mary of Cambridge, *Czar Peter, and *De Candolle. *Single Yellows*.—*Ida and *Bird of Paradise. The very best eighteen varieties for superior colour and massive spikes are those to which an asterisk is prefixed. The single varieties are mostly to be depended on for their easy culture and fine flower trusses, but if a few doubles are desired, Blocksberg, Laurens Koster, and Van Speyk are among the best of the blues; La Tour d'Auvergne, Prince of Waterloo, and Anna Maria of the whites; and Koh-i-Noor and Lord Wellington of the reds.

Cultivation in Pots.—Rich light soil is of the first importance. We prefer that which has had a large quantity of dried cow manure and coarse gritty sand mixed with it some time previous to being used. For exhibition purposes we pot the bulbs singly in 32's or 6-inch pots, but for home decoration 48's are often used. Some cultivators place three bulbs in a pot, but we prefer one. If the pots are new well soak them, for the white fleshy roots of the Hyacinth have a great dislike to new pottery. Fill the pot with the soil, make a hole with the forefingers, lay on a little silver sand, and place the top of the bulb on a level with the top of the soil; a rap on the potting bench will settle all firmly around the bulb. When potted they should be placed on a bed of coal ashes and be covered over to the depth of 5 or 6 inches with cocoa-nut fibre refuse; here they must remain until well rooted, which is generally from six to eight weeks from the time of potting.

Hyacinths in Water.—The single varieties are to be preferred for this purpose. Fill an ordinary Hyacinth glass with rain water, placing the bulbs on the top made for the purpose, almost but not quite in contact with the water; place them in a dark room for a few weeks until the roots have grown down the sides of the glasses, when they may be removed to the light; a window is a very good place, as the close contact with the light and air prevents them from becoming drawn. During severe frosty nights they should be removed a distance from the glass.

Early single Tulips are very showy and bear forcing well, and precisely the same sort of compost and the same size of pots and the same treatment recommended for Hyacinths will suit Tulips, only instead of one bulb, as in the case of Hyacinths, placing three around the sides of the pots. The following are among the best varieties:—Bride of Haarlem, Chrysolora, Couleur de Cardinal, Keizer's Kroon, White Pottebakker, Proserpine, Van der Neer, and Vermilion Brilliant.—J. W. MOORMAN.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

KITCHEN GARDEN.

We have done but little work this last week in this department, but surely never has the weather been better for pushing forward out-of-doors operations. No rain to speak of has fallen for more than a month, and the ground is perfectly dry. Our northern friends will be surprised to hear that in this season of floods we have a border of Coleworts with the leaves flagging very much and of the usual bluish tinge that they take on in seasons of drought. We hope they will soon have a soaking of rain, as it is rather too much to expect us to water Cabbages in October.

No time should be lost in having all spare ground dug or trenched. It is sometimes better to trench it, especially if the soil is very poor, as the trenching affords an opportunity for working-in a good proportion of manure. Some persons fancy that it is waste to place manure deeply in the ground; if we had only a small quantity we would not care to bury it a foot below the surface, as this would not be using it to the best advantage. It would be much better that it was buried about 5 or 6 inches; but in trenching we have a layer at the bottom of the trench, then a spit of earth with the shovellings, and over this another layer of manure. We obtain excellent crops from our light soil by treating the ground in this way, the crops are more independent of the weather, and will pass through a season of drought that would seriously injure the crops if the ground had only been dug up. We have done much hoeing. In this district there ought not to be any excuse for the ground being overrun with weeds during the winter months. Should slugs attack the leaves of the young plants of Lettuce, Cauliflower, Cabbage, &c., the best way to destroy them is by dusting the leaves at night with dry lime. This was noticed last week, but the remedy is a very simple one, and if it is attended to in time the plants will not suffer. If the principal leaves become riddled with holes the plants receive much injury.

VINERIES.

Those who intend to start their Vines early, say in November or early in December, ought to lose no time in getting them prepared. Ours have been pruned some time ago, the wood

painted with sulphur dissolved in soapy water, the walls washed with strong lime water, and it is also well to paint the hot-water pipes. Surface-dressing the borders ought not to be omitted annually. Of course there is some difference of opinion as to the best method of doing this. We know of a good Grape-grower in Scotland who saves up a quantity of solid cow manure for this purpose, and when it is twelve months old it is ready for use. About 3 or 4 inches of the surface soil is removed, or even more, according to the nature of the roots, and about 2 inches in depth or rather more of the manure is then spread over the surface, and over this the same depth of turfy loam. The roots run freely into this dressing and the Vines are much invigorated; the Grapes are, we think, also of better flavour than they are produced when guano or other hot manures are used. Our own dressing is rather different from this. We mix cow manure and horse droppings from the stable in about equal proportions. There ought to be enough stable manure to cause the whole mass to heat; this dries the cow manure, and after it has been turned over frequently for three weeks or so it is ready for use. The manure and decayed turfy loam is then mixed together in equal proportions, and this forms a most excellent compost for surface-dressing Vines.

When the leaves are falling in the late vineries the Grapes have much tendency to become mouldy. Remove the leaves at once, and all berries that show the least tendency to decay. Open the ventilators on all favourable occasions, and close them before the night dews come on. Unless the weather is very cold and a sharp frost is expected it is better not to have any heat in the hot-water pipes. Our own experience with late-hanging Grapes is to keep out damp and not cause moisture to arise from heating the pipes at night. In our district thick fogs all day long must also be kept out. So far there has been no reason to complain, and the state of the Vines show that we may expect good crops of Grapes next year.

Orange and Fig trees in Pots.—To grow either of these fruits well it is desirable to have the plants near the glass; they must be regularly syringed, and considerable care must be taken as regards watering them. They suffer from too little water, and if the drainage is imperfect the soil becomes sour and the flavour of the fruit is deteriorated. Fig trees are now approaching the resting season, and water must be gradually withheld and the soil must just be prevented from becoming dusty dry until the period of starting them into growth again. We pot our Fig trees annually, and it may be done any time during the resting period. The plants make an immense quantity of tough fibrous roots and require generous diet. Good yellow moderately clayey loam, which is the best substance in which to grow all our choice fruits, is also the best for Figs, and as much water is required so that the drainage is well put in and some tough fibre placed over it to prevent the finer particles from mixing with the potsherds; about one-fifth part of decayed manure should be mixed with the loam, and an 8-inch potful of crushed bones to each barrowload. Firm potting is also an essential towards success. Many persons fancy that Figs can be grown at a great distance from the glass and under the shade of Vines. This is a great mistake. It is not possible to grow them so. The fruit produced is worthless, the leaves being very thin and a prey to red spider. Orange trees will not do well under the shade of Vines either, and it is best to do without them rather than to grow trees that will only be a discredit to those who have charge of them. Many amateurs fancy that if they have two or three glass houses they are going to have everything in the way of plants and fruit trees. We know one who built a greenhouse and was quite taken by surprise when told that it would not be possible to grow Vines, Melons, and Cucumbers in the same house. People must not only learn this, but they must also learn that a greenhouse cannot be kept gay with flowers from November to October without forcing pits and frames, from which a supply of plants may be obtained as others go out of flower.

This has also been a very good season for Strawberry plants in pots. The heavy dews at night and the leaves having been occasionally crusted with frost has stopped the growth of red spider. We still carefully attend to watering the plants, as also cutting off any runners as fast as they appear.

PLANT STOVE AND ORCHID HOUSES.

The work is much the same as we described a week or two ago, and we are still washing plants and having them thoroughly cleaned. Flowers are now rather scarce, and where plants are in flower it is best to take as much care of them as possible. *Allamanda Schottii* generally gives us plenty of flowers at this season, it is doing so now. We have also several of the *Ixoras* in good condition; *I. Williamsii* has some huge trusses of bloom on small plants; the pure white sort *I. Coleii* gives us plenty of trusses, but they are small, and the white is not very pure. This variety likes plenty of heat, and then it is a very desirable variety. *Gardenia florida* is also supplying us with its delightfully sweet flowers, which are never unwelcome; and the noble *Amazonian Lily* (*Eucharis amazonica*) has also been doing good service.

Amongst Orchids the *Dendrobium formosum*, autumn-flowering sort, is at present very beautiful; its large pure white flowers, with a yellow blotch at the base of the lip, are a great boon at this season of the year. This variety ought to be distinguished with an addition to its name, as a confusion is caused from the want of this. Those who want *D. formosum* to flower in June and July would be grievously disappointed if they received the sort that flowers in September and October; but it would not be fair to blame the nurseryman if he had no definite instructions. The growths are also quite distinct. The summer-flowering sort has darker-coloured and more hairy growths than the late-flowering variety, but the flowers are not to be distinguished. *Miltonia candida* is very useful for flowering at this season. Although the flowers are not very striking they are freely produced, and are useful for cutting to fill vases or for bouquets. Where there are a dozen plants of *Phalenopsis* flowers may be produced all through the winter and spring months. We now have *P. amabilis* in flower, and also other species showing. The *P. grandiflora* has the largest flowers and is the best amongst them. We do not give these plants very much water at this season, but only sufficient to keep the sphagnum alive, and carefully prevent any water from falling on the leaves. The winter-flowering *Calanthes* have formed immense bulbs this season, and are now throwing up vigorous flower spikes. They are in very small pots for the size of the plants, but the longer we grow Orchids the more are we convinced that the most satisfactory results are produced by growing all the plants in small pots.

FLOWER GARDEN.

The frosty nights that we have had caused us to lift all the Pelargoniums that we required. We do not pot-up any of the green-leaved sorts, as for the small beds and comparatively narrow borders plants from autumn-struck cuttings are the best, and they grow quite large enough by the end of the season. We pot the tricolor varieties, using very small pots. A good-sized plant may be potted into a large sixty. Before potting, all the large and oldest leaves are removed, but it is better not to cut or pinch the shoots. The beauty of most of the beds is now quite over, and the plants are being removed and the ground prepared for spring plants. Roses have flowered very well this autumn, but the mildew has seriously checked their growth and deteriorated the quality of the flowers. On a south wall the single white *Macartney Rose* is a conspicuous object, and very attractive to visitors. With us it has produced a succession of flowers during the summer months, and the plant seems as if it would produce them a month longer.—J. DOUGLAS.

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (—).—"London's Encyclopedia of Gardening" explains the terms genus, &c., which you need.

TROPEOLUM (A. F. B.).—It is *Tropeolum tuberosum*.

CARBOLIC ACID (M. A. B.).—Those who report favourably of its use to destroy weeds on walks are reliable authorities. It need not be applied so close to the edgings as to affect either the lawn grass or border flowers.

GRAPES (Curiosity).—A Grape within a Grape, like an egg within an egg, is a phenomenon unexplained. The small berries are with seeds unfertilised.

SEEDS OF COLOURED PRIMROSES.—A Castleton subscriber asks where these seeds can be obtained.

REPORTING (J. M.).—Thanks for your commendation, but we cannot be our own trumpeters.

SEED (Addlestone).—We cannot name a plant of which we are only shown a seed.

POTTING ROSES (X. X.).—The Roses which were forced last year ought to have been potted a month ago, but they will do well if potted now. *Lapageria rosea* and *L. alba* do best planted out in a border of turfy peat. See that the border is well drained.

RAISING EPIPHYLUM FROM SEEDS (E. L. L.).—The seeds should be removed from the pulp and be carefully dried by exposure to the sun. Sow them in sandy loam, just covering them over with the finer particles. The seeds may be sown at any time in the year, early spring being, perhaps, the best time. The night temperature of the house ought not to be less than 55°.

HALF-SPAN VINERY (Inquisitive).—Your wall being 9 feet high the vinery may be of the same width, with a front wall 2 feet high, which will give 11 feet of rafter. The Vines should be 18 inches from the ends and 3 feet apart, so that for six Vines a length of only 18 feet will be requisite. Vines and Peaches answer very well in the same house, but they cannot be forced together. A border the width of the house will suffice for the Vines for a few years; it will therefore be well to plant the Vines inside the house,

making arches in the front wall for the roots to pass outwards when an extension becomes necessary.

PLANTING FRUIT TREES (Ploughboy).—An article on the subject will appear next week.

RAISING FUCHSIAS FROM SEED (A Young Gardener).—When the seed-pods are black and juicy the seed is ripe. Press them with finger and thumb, wash away the pulp, and spread the seed upon paper to dry. Sow in rich soil early in spring, placing the seed-pans in gentle heat, such as is found in a cucumber bed or propagating pit, pricking the seedlings into pots so soon as they are large enough to handle.

WINTER SHELTER FOR PLANTS (Thomas Watson).—*Sedum variegatum*, *Valloia purpurea*, and the *Daphne* might be kept plunged in ashes in a cold frame as you propose, but *Phoenix dactylifera* and *Dracena australis* require a greenhouse. *Ficus elastica* may be kept in tolerable condition in a greenhouse, where also may be placed *Oxalis rosea*. You are quite right about the name of the Palm.

PROPAGATION OF PHLOXES (Idem).—All the hardy perennial varieties are propagated by cuttings made early in spring and placed in heat, or later on throughout summer in cold frames or under hand-lights, and also by division of the stools. *Phlox Drummondii* is raised annually from seed sown in March or April.

PLANTING ROSES (Sambo).—If they are planted at this period of the year, and if the weather is dry, they require watering at the roots and syringing at the tops, also the soil covering with manure as a top-dressing. Decayed manure mixed with the soil would be beneficial. Your other questions will be answered next week.

PLANTING ROSE BEDS (Flora).—Roses which are grown for exhibition purposes or for the excellence of individual blooms should not have any other flowers mixed with them. If the Roses are grown for ordinary garden decoration, and fine blooms are not required, other low-growing flowers, especially bulbs in spring, and Stocks, Mignonette, &c., in summer, are permissible in the beds. Violets would not do any serious injury if not planted close to the stems of the Roses, and if an abundance of liquid manure was applied to the beds throughout the summer months.

WATSON'S LAWN SAND (C. M. Buckden).—Mr. A. D. Barbour, 3, Park Row, Leeds, is the principal agent.

STRONG GLASS FOR A CONSERVATORY ROOF (R. J. S.).—Ribbed glass answers perfectly for a conservatory roof, proving no hindrance to freedom of growth and flowering, but clear glass is preferable for the sides.

HEATING A CONSERVATORY (Idem).—Hot-water pipes are altogether preferable for a conservatory, no other method being so cleanly and none more efficient.

SOWING GRASS SEED UPON A LAWN (G. S.).—It is too late to sow grass seed, and you must wait till the end of next March; then stir the soil of the patches a foot deep, removing any of it in which may be found the spawn of fungi (a white thread-like substance), replacing it with fresh and tolerably rich soil, renovating the old soil with a little well-decayed manure and sowing the seed immediately. The condition of the entire lawn may be much improved by a liberal surface-dressing of soot thrown about during February or March in a showery time, so as to be washed downwards to the roots quickly.

ASPARAGUS CULTURE (Old Subscriber).—There are five conditions essential for obtaining an abundance of fine Asparagus. 1, Beds well drained. 2, Abundance of rich dung in the autumn. 3, Weekly sprinklings of salt and strong liquid manure during the whole period of growth. 4, Leaving off cutting by the middle of June. 5, Not cutting down the seed stems until they are quite yellow. *Making the Bed.*—This is best done at the end of March or early in April, this being the best time also for planting. If the ground is common loam and well drained, or having a subsoil of gravel or chalk, nothing more is needed than to trench the space intended for the bed, and to mix with the soil as much rich thoroughly decayed dung as can be worked in. The trenching should be done now. Two-year-old plants should be chosen when they have started into growth 2 or 3 inches; they should be forked out carefully, and their roots not allowed to get dry after being taken up. No heads should be cut the first year after planting, and very few the second.

SAWDUST AS MANURE (F. C. H.).—All vegetable matters are promotive of fertility when mixed with the soil. Sawdust decomposes slowly and becomes soluble in the moisture of the soil. It is especially useful in rendering the staple of a heavy soil more open.

WHITE SCALE ON CAMELLIAS (L. J.).—Sponge the plants thoroughly with soap and water.

NAMES OF PLANTS (J. G. Gardner).—1, *Begonia fuchsioides*; 2, *B. Ingramii*; 3, *Begonia Weltoniensis*; 6, *Pteris serrulata*; others not recognised.

POULTRY, BEE, AND PIGEON CHRONICLE.

AGRICULTURAL HALL POULTRY SHOW.

The entries were small in proportion to the prize money offered. The birds were ranged on three sides of the galleries, where in most places the light was good. The Judges were Messrs. Hewitt, Teebay, Nicholls, Smith, Martin, and Leno. The days of the Show were far too many, and we are afraid many birds will be the worse for their long incarceration.

The *Dorkings* came first on the list, and the two first birds in the catalogue were Mr. Burnell's cocks which won second and fourth prizes. The second was a good-framed square bird. The condition and size of the first pullet was capital, but the whitest-footed bird in the class was the third, and perhaps should consequently have been higher. The next class had some very good Silver-Greys, and an excellent pen of Whites which came in third, and neat Silvers fourth. The first *Spanish* were good and won easily. We placed them first long before the cards came round. *Minorcas* and *Andalusians* met in the next class and made eleven entries. First and second went to the first-named breed. The *Cochins* were on the whole extremely

praiseworthy. The winning Buff cockerel was a very pretty bird, its neck hackles are not out, but his colour is sound, and had he more leg-feathering would make himself a good name. The second, however, had far too much in this respect, and his heavy hocks and coarse leg-feathering made him look ungainly. The fourth was a pretty chicken, his wings a little poor in colour, or else he should certainly have had a higher place. In pullets the winner was large and shapely, but had not an attractive head; the second was very pretty in colour but very small. Mrs. Alsopp and Lady Gwydyr both sent good pullets. In Partridges the first chickens had the cup, and both were good. The second was also a good pen, the cockerel shapely and bright in colour. The pullet in the fourth pen was the Aylesbury winner, a pretty bird but small, and not equal to the lovely pullets of Mrs. Acton Tindal. In Whites we liked the Judge's choice for first and second; the pullet in the latter pen was perhaps the best, but the first cockerel was whiter, and both were really shapely pens of chickens. For third place we should have gone to pen 95 (Breeze), which contains both the Aquarium first-prize winners, but the cockerel wants more breadth and chest. In Blacks the first were easily winners, broad and in wonderful bloom, the cockerel very young but of much promise. The second were also good and bright. The third we did not like at all; they had long tails, and the pullet's comb was hideous. Mr. Darby showed good pullets, but we are told his pens came too late for competition.

In Dark *Brahmas* the first cockerel took the champion sweepstakes. He is a good-looking bird, well feathered, and broad. The second was showy and good, but had some brown in his wings. The shape of the third was capital, but he was too heavily feathered; his colour, however, was beautiful. The first pullet had also full enough hock-feathering, and was large and well marked. The pencilling of the second, too, was good, and so was the fourth. In Light cockerels we thought the winner won well; he is a good bird all round. The condition of the second was fair, but his comb was ugly, and the same applies almost to the third. In pullets we liked the winner. She is good in colour, well marked, and neatly feathered. The other winners were good and well chosen. We were sorry to see Mr. Breeze's best pullet in so bad a plight, and on inquiry learnt that the basket in which she was drying caught fire, and before it could be extinguished she was dreadfully scorched, and her face and comb presented a very woe-begone appearance.

In *Game* the cup went to a Black Red cockerel, a bird good for colour, but his wings were untidy, and we imagine the second ran him close. In Black Red hens the colour of the second was good, but her comb was poor. In Brown Red cocks the winner was a fair bird, the second, however, running him closely. In hens of this colour the winner was a pullet in good bloom. In Duckwings the winners were very stylish; the third cockerel, too, was good, and perhaps had he had a matured pullet would have stood higher. The first Pile cockerel was rich in colour, undubbed, and with much style; the second was also undubbed; the fourth were smart chickens and in hard feather.

In *Hamburghs* the cup went to Blacks; they were a lovely pen, in fine condition and very glossy. The rest of the winners were good, and we especially admired the first Silver-pencils, first and second Golden-pencilled, and the first Silver-spangled cockerel, as also second pullet. The Golden spangles, too, were of great merit, the hens and pullets especially; their moons were large and colour rich. In *French* the Houdans and Crêves were both splendid collections, and though the first Crêves were rather out of plumage their size and points were admirable. The second, too, were wonderfully large and good, as were Mr. Stephen's two pens. Of Houdans there were a score of entries, and the first chickens were very large and good in comb. Second and third were old birds with but little difference between them. The fourth were very large and excellent in shape.

The *Leghorns* in two classes made fifteen entries. The winners were well chosen, and the Judge, who was, we believe, Mr. Nicholls, seemed to know just what to select. The *Polands* had two classes and only made eleven pens, but the quality was all that could be desired. The cup went to Black chickens, a very beautiful pen. The cockerel in the second had lost his tail, but his crest was huge and very white. The third were old birds, the hen lovely but the cock in moult, and his pen was full of feathers. Fourth were chickens again, but the pullet here had an ugly division in her crest behind. In the Spangled Golds were second and fourth, while Silvers had the other two places and were well marked and good, the third being old birds which want more time. *Malays* made but five pens, and the Judge had no difficulty to place his four prize pens in the proper order. The Variety class was truly excellent, there being twenty pens of admirable quality; first went to La Flèche, second to Sultans, third to Cuckoo Cochins, and fourth to Japanese; Silkies, good Scotch Greys, Cuckoo Cochins, Plymouth Rocks, &c., coming in for other cards of notice.

In *Waterfowl* the cup Aylesburies were very large and white, and the first Rouens were large and good; but we cannot comment on the winners for there seemed to have been some little

uncertainty as to which were the winners on the first day of the Show. The Pekins were excellent, and we are glad to see them making progress; and we regret we cannot say the same for the East Indians, which seem very few in number and out of fashion, and they will continue so while the Judges insist on such small size, almost disregarding colour for it. Mandarins and Carolinas had no entries. In the Variety Waterfowl class good Spotted-bills were first. Geese came fourteen pens strong and were good indeed, the first going to the Ipswich winners we believe, a most excellent pen of Greys. But the Turkeys too made a splendid display. The first contained a grand hen remarkable for her rich colour and size; but the best cock was in the third-prize pen, a huge bird in fine condition. We quite grant the first hen won them the place fairly, but we liked the third better than the second. In neither pen, however, was the hen very large. The farmyard cross class produced a trio of pens, and again exemplifies the mistake of putting such a class in an exhibition of fancy poultry only. The first went to what were apparently Black Dorkings, the second to a cross between a White Dorking cock and Light Brahma hens, and the third were mongrels of some kind with some Asiatic blood somewhere about them.

The *Bantams* call for no particular remark, for by some stupid regulation the price of each pen was limited to 40s., and the consequence was the classes were but meagrely filled with inferior specimens save the Game birds of Mr. Entwistle, and if they sold for 40s. a pen someone had some bargains. Many pens were entered at other high prices, but these will of course not have the prize money, for it will be surely allotted to the next best in gradation. And we are shown by this how extremely careful all ought to be in reading the rules, for even such a frequent exhibitor as Mrs. Acton Tindal did not notice this limited price, as her beautiful Black Rosecombs were entered at £10. We doubt ourselves whether the Secretary should have catalogued entries above the restricted price.

POULTRY.—**DORKINGS.**—*Coloured.*—Cockerel—1, H. Lingwood. 2 and 4, T. C. Burnell. 3, Rev. H. R. Peel. Pullet—1, H. Lingwood. 2, Mrs. Radclyffe. 3, T. C. Burnell. 4, H. Lingwood. *Any other variety.*—Chickens—1 and 2, T. C. Burnell. 3, Mrs. M. Hayne. 4, Miss Pallas. *SPANISH.*—1, J. F. Siltoe. 2 and *chc.* J. Powell. 3, W. H. Lowe. *MINORAS AND ANDALUSIANS.*—1, J. Harwood. 2, J. B. W. Williams. 3, C. Naylor. 4, Miss M. Arnold. *COCHINS.*—*Buff.*—Cockerel—1, Lady Gwydyr. 2 and 4, Mrs. A. Tindal. 3, —Allsopp. Pullet—1, Mrs. A. Tindal. 2, Mrs. A. Christy. 3, J. CHAMPION SWEEPSTAKE.—1, H. Lingwood. 2, S. Matthew. 3, Mrs. A. Mayhew. 4, Mrs. A. Tindal.

OXFORD POULTRY SHOW.—As we promised last week to furnish the various classes which each Judge at the above Show would adjudicate upon, we now proceed to do so. Mr. Hewitt will take the Dorkings, Spanish, Cochins, Brahmas, and French, also the Black, Sebright, and Variety Bantam classes; the Black, Pekin, Call, Mandarin, Carolina, and Variety Waterfowl classes, with the Pheasants and Turkeys. Mr. Teabay will have the remaining poultry classes. In the Pigeons Mr. Allsopp will take the Carriers and Dragoons; Mr. Jones the Barbs, Antwerps,

Owls, Turbits, Jacks, and special Flying class; while Mr. Esquilant will judge the remaining Pigeon classes. The date of receiving entries has been extended, but all must be posted this day to be in time; and we hope that those who have not already entered will consequently not delay doing so any longer, or they will be too late.—W.

TONBRIDGE WELLS POULTRY SHOW.

THE entries at this Show in many classes were small, but the quality was better than we ever saw here. The Show was held in a large marquee in the fields below Broadwater Down, and Mr. Ware, the member of the Committee who peculiarly interests himself in this department, was most courteous and obliging.

In *Dorkings* a very good pen of Silver-Greys were first, and they also won the extra prize for the best pen in the Show. Mr. Boissier is to be congratulated on the exquisite condition these birds were shown in. Buff *Cochins* were moderate. The winners (Christy) were well shaped, but the pullet wants more time. The second cockerel (Stephens) was not very good in wings, but was neat in shape; and the cock in the first prize Whites (Boissier) was well shown and good, but the pullet with him quite unworthy of his company. The first Dark *Brahma* chickens (Lingwood) were well-grown birds in good order, and well first. Mr. Breeze's first Lights too were good, though the cockerel was fully too dark on his saddle for our taste. The first *Spanish* (Hunt) were excellent, as too were the *Créves* of Mr. Stephens which won first and second prizes. *Hamburghs* were good. The winners were Golden-pencilled (Sales), and a very good pen of Silver-spangles (Avenell) shown in faultless condition and good in markings won in the other *Hamburgh* class, Blacks being second. The *Game* were quite a meritorious lot, and were well judged. We seldom see better Piles at great shows than we did here. The Variety class was small, first going to old La Flèche (Stephens), rather untidy in appearance; second to the same owner's La Flèche chickens, and third to small and pretty Sultans (Mrs. Christy). In the Selling classes the Light Brahmas of Mr. Pitt which won both first prizes were excellently-grown birds. In *Bantams* Mr. Leno won first with moderate Laced. The Aylesburys of Dr. Snell and the Rouens of Mr. Ware and Mrs. Brassey were up to a high standard, and in the variety Waterfowl class very large but too yellow in colour. *Pekins*, the first were exhibited by Mr. Kitchin. *Turkeys* were capital; the winners (Warde) were very large and in good feather.

In *Pigeons* Mr. Chandler monopolised most of the prizes with good specimens of Carriers, Ponters, &c.

The Judges were Mr. M. Hedley, Mr. J. Nicholls, and Mr. Harrison Weir. The Show was well attended and the awards favourably received.

THE MANAGEMENT OF SMALL RABBITS.

SMALL Rabbits are the Angoras, Himalayas, Siberians, Silver-Greys, Silver-Creams, Polish, Dutch, and the common prick-eared varieties. Another subdivision into the hardy and delicate varieties will also be useful. The hardy class we consider are Himalayas, Silver-Greys, Dutch, and Siberians. The delicate are the Angoras, Silver-Creams, and Polish. The delicate do best with a little heat, while the hardy, with the exception of Silver-Greys, would not care for additional warmth.

Of course the hutches for the small breeds need not be so large as for those which are more than twice the size, and they need not be so high, although the larger and higher they are the better. For the smallest sorts, such as Dutch and Polish, 2 feet 6 inches by a foot by 10 inches will be large enough, although 3 feet and a foot should also be the limits for length and height respectively, and nothing less will do for such as Angoras or Silver-Grey. An extra inch or two in height and half a dozen in length is never thrown away; and if the hutch is properly made without any draught holes there is little fear of the increased size making the inmates cold, while the increased facilities for exercise cannot fail to be very beneficial, especially to the younger ones. The sleeping compartment should be made a little smaller, and also the hole of communication. The partition need not be fixed more than 10 inches or a foot from one end, as if larger it will not keep the inmates so warm. The wires should be closer together, and if not quite so strong it will not matter.

We have classed Himalayas, Silver-Greys, Dutch, and Siberians as hardy Rabbits. They are remarkably strong and free from disease, and do not require any heat. A little warmth will, however, tend to develop the Silver-Grey's shading satisfactorily. All can be kept out of doors, and will do with but little corn. A good supply of healthy green stuff twice a day, with one feed of dry stuff, will do all that is required, especially as they are not required to be kept very fat. They are all very prolific and good mothers. The young Himalayas are born pure white, the points darkening with age. When about a couple of

months old the points get a grey colour, and gradually get darker, until at about six months old they become a light brown. This darkens for another month or two, when they will be as dark as they ever will be. The most critical period is when they are about three weeks old, at which time they should be very carefully looked to, for they pass through a moult and disease in the same way as puppies pass through distemper. The young Silver-Grey are born quite black, and continue that colour for a few weeks, when by degrees a few light hairs make their appearance, and the shade gradually increases in intensity till the legitimate silver-grey is arrived at. The most annoying feature is the nose, which is often white. The head generally is darker than the rest of the body, and this is no defect, although generally speaking the more uniform the shade the better. Young Siberians are also born quite white, or rather pink, and continue whits for a couple of months or so, when the ears, nose, and feet begin gradually to look dirty and by degrees brown, till at about nine months they are at their best. They should be kept dry and clean, and the hair should occasionally be combed. The colour of the little Dutch, however, can be discovered almost immediately after birth, and after a week can be told to a nicety, an old hand being able even at that early period to give the approximate worth of each member of the family. They develop rapidly, and at three months the colour is as good as it ever will be: hence it is that very young Dutch often run off with prizes, while the young of other breeds seldom do so, owing to their points not having developed. The Dutch doe is the most prolific of all, and the best mother: hence she is often sold and used as a nurse doe, either to relieve a doe with a large litter or to take the place of a deceased mother. In either case, with a little judicious care, they do their work well and give general satisfaction.

The delicate varieties, in which division we have placed Angoras, Silver-Creams, and Polish, require more care and want some little warmth to develop them properly. Polish Rabbits are particularly delicate, and as they are not so prolific as the others, nor does their scarcity make them more prized, we hardly recommend their being kept, especially as it is only a person who has seen the two together that can distinguish between a specimen of the breed and a common Rabbit white with pink eyes. At present there is not much pure Silver-Cream bred, nearly all the specimens shown being the products of a cross. The young of the Angora are born pink and bare, but the wool comes very quickly, and they are soon covered with a thin layer of silk. They are very delicate, and seem affected by the cold more than any other breed, except, perhaps, the Lop, and if they are kept in outdoor or draughty hutches they are a very long time getting properly fledged. For the first two or three months they require a good deal of care. This breed at all times requires a little extra care to prevent its long woolly coat from becoming matted. A comb worked through the hair gently once a week is a good thing, taking care not to tug when there are knots, as the poor animal's skin is far from strong, and it will show plain signs of pain by wincing. A specially roomy and clean hutch and a careful selection of bedding are also necessary to insure perfection. If the wool becomes very badly matted the worst parts should be cut off, and the hutch kept a little warmer till it grows again. If you can catch them at a moult it would be as well to cut the hair off altogether, carefully combing the new hair as it makes its appearance. The best and prettiest Angoras are those with very long wool parted down the middle. In fact, great care should always be paid to the wool, which quickly degenerates into masses of filth if not attended to; in fact, the easier it mats the better the quality.

The three varieties last under notice all require some sort of heat, as also do Silver-Greys. The Angora does are best with a little warmth, but not too much. If there is not heat the wool will not be so fine as could be wished, and if there is too much the ears will grow long and flabby, falling something after the fashion of the Lop. Both of these are to be avoided. The Silver-Grey and Creams both want to be shielded from the cold wind, and a little warmth will assist the shading process. The Cream is certainly the more delicate of the two, and hence requires more care and attention, and also a little warmer temperature. As a rule, however, the foreign varieties of Rabbits do with but little artificial heat.—GETA.

CHICKEN-FEEDING.—There is one ingredient in chicken-feeding which deserves special notice, being of the greatest assistance to those whose space is limited. We allude to the bone-dust, or ground dry bones, which is often used by gardeners in potting plants. For the knowledge and use of this ingredient we had originally to thank Mr. John Stuart of Helensburg, well known in Scotland as a successful breeder, and to whose unvarying friendship in many other ways and instances we feel pleasure in acknowledging heavy obligations. After full and satisfactory trial ourselves, we had no hesitation in recommending the use of bone-dust to other breeders; and the extent to which other writers have followed us in various periodicals, and to which

the substance is now advertised in the poultry papers, besides the many private testimonies we have ourselves received, are conclusive evidence of the value of an article of diet which Mr. Stuart's kindness had enabled us to be the first to introduce generally to poultry breeders. Bone-dust for mixing in poultry food should be on an average about the fineness of coarse oatmeal. There are usually larger pieces interspersed, but these need not be taken out, as any too large will be rejected; though the meal may be sifted free from any larger than peas if desired. The price being never very much more per hundredweight than good meal, it should be used liberally with all the soft food, and about an ounce may be mixed with every half-pint of dry meal before adding the milk or water.—(*The Illustrated Book of Poultry.*)

THE BEE SEASON IN HERTS.

ON former occasions I have given your readers some account of my bees and their doings near Hitchin; and as we may now consider the season for 1877 closed, it is my purpose to tell a little of my year's experience and of the lessons I have been taught by it. Last season was one of unusual abundance of honey, this season has been a very different one, although I am happy to say that I am not obliged to mourn with those who have had no harvest at all. All my hives have done something. Some have given me no surplus of honey in supers, but these have one and all given me powerful swarms, which in five cases out of eleven not only filled their hives (all ten-framed wooden hives) with combs and sufficient store to carry them on to next March, but also filled sectional supers weighing from 10 lbs. to 35 lbs. each.

This result was brought about by two causes. Each hive into which a swarm was placed had its frames filled with clean old comb purchased from cottagers whose bees had died out during the winter and spring, or the bars were furnished with from 4 to 6 inches of midrib moulded and fixed according to Mr. Cheshire's method, and in the second place all the swarms were thus hived before the second week in June. No swarms were hived after this period, but were returned to their parent hives after the queen cells had been excised. From experience I knew that my honey harvest could only last for three or four weeks, and that it would commence early in June. As it turned out, the season was a late one, and the clover was not in flower till about the 12th of June. After cold wet weather a sudden change took place, for me in the nick of time, and a fortnight of lovely sunshine and hot weather arrived. Honey was abundantly secreted in the flowers, and my bees worked merrily up to the 24th, when a change came—a sudden unwelcome change. Copying from my diary, I find:—"June 25th. Wind N.E., much colder; bees get out to work much later than yesterday, and are all home soon after 5 p.m. Many forsake their supers during the cold night." This proceeding went on until I find under date June 28th—"Most of the clover cut." From that date very little honey was stored in supers. On some hives where the supers were nearly finished a few fine days during the lime blossoming completed them, but all my best supers were worked before the 25th of June. The greatest quantity taken off one hive, a stock which did not swarm, was 63 lbs.; two Lee's Crystal Palace supers, 45 lbs., and the rest in sections worked over the Lee's supers. Some time since Mr. Abbott inserted a letter of mine which bore testimony to the wonderful results brought about by the employment of midribs in supers made from a plaster cast of natural comb.

Mr. Hunter has told you of the midribs which are made by an American invention. I hope to be able to test some of them, and to note the results obtained from their use in comparison with those obtained from the plaster casts. Given the casts, I cannot see how the bars of frames can be supplied with guides in a neater and more expeditious manner by the machine-made sheets. But midribs whether made by one or the other method are essential to bee-keepers who wish for straight combs and quickly filled supers. A Lee's super, seven bars, which when sealed-up weighed 22½ lbs., was filled from end to end with comb worked on these midribs given the whole depth (4 inches) of the super, stored and sealed under sixteen days. Frames in stock hives supplied with the same depth of guide sheets are one and all built perfectly straight, and have given me this autumn no trouble whatever to lift out one by one, full frames being transferred from hives with bounteous stores to weaker brethren, and the lighter put in their places, all fitting nicely together, and affording me the greatest pleasure to manipulate them.

Next week I hope to tell you what advantages I have found by the use of perforated zinc between the stock and supers, and of some interesting and instructive accidents which happened through its employment; also my experience regarding Ligurian bees, which I have this year had for the first time, and to which I have tried to give particular attention, carefully noting any faults or excellencies in them as compared to our old friends the so-called black bees.

I think that my experience of the year has more than ever

impressed upon me the importance of gentle stimulative feeding in early spring, both with barleysugar or syrup and pea flour, in order to have a powerful army of workers, early swarms, and hives full of hatching brood before the honey season, which is so short in our cold climate, commences. The stocks of the cottagers near here who cannot be brought to attend to their bees, but who have kept bees, some of them for fifty years, swarmed (where they swarmed at all) in the very midst of the short period of ingathering, some "hanging out" for days, and wasting those precious hours only to be found this autumn not worth the trouble of "taking up." Yet for all that many went down into the sulphurous pit. An old man who has kept bees for nearly sixty years, who likes to walk round my garden and see the bees filling the supers, yet who cannot be brought to employ any new methods, has this year burnt all his bees unknown to me until too late to save them. He tells me that they had done nothing for him for some years now, and that he had given them up in disgust. The first week in July I heard him talking in an excited manner to a neighbour, and as I passed he called out to me to tell me that "The Lord had sent him a swarm of bees." None of his own had swarmed, but a powerful colony had settled on his chimney. The neighbour hived them, and left the skep on the roof. In the evening not a bee was in the skep, all were in the chimney, the queen, doubtless, not having been secured at the first. Here the bees remained until during my absence from home last month they were smoked out, a few pounds of honey obtained, and an immense quantity of valuable comb thrown into the "boiling pot," their more lowly sisters perishing the same evening. In contrast to this "wilful sinner" is a young man, an invalid, who has by my directions increased his one stock of the spring of 1876 to five powerful hives, one a bushel skep, into which he placed two powerful and one weak swarms, and from which after driving the bees he obtained over 40 lbs. of valuable honey. The bees were returned, and are being fed-up into a splendid colony. A super of 8 lbs. was obtained from another hive, and now the five are in good condition to pass through a long winter. The next step in the right direction will be the employment of bar-frame hives. My own stocks are now thirty-one in number, only five of which remain in 18 or 20-inch skeps, all the others have found their homes in bar-frame hives, and those of the five skeps will do the same as soon as I can make hives into which to transfer them.—P. H. PHILLIPS, *Offley Lodge, near Hitchin.*

BEE-KEEPING IN NORTHUMBERLAND.

I HAVE three large hives which made over 20 lbs. each on the moors in spite of the weather, whilst the small hives made only from 5 lbs. to 7 lbs. I can safely say that no other hives within ten miles have made more than 7 lbs., hundreds of hives have done nothing, and scores have died out. Such a season has not been experienced for many years. Though the season has been unfavourable I consider that I have been a gainer by increase and improvement of stock, for I have three large hives worth £6 6s.; three smaller, £4 10s.; one ditto, £1 5s.; one large hive with bees, given to me for driving them, £1 10s.; 14 lbs. of fine honey, £1 1s.—total, £14 12s.; deducting £3 10s. cost, and sugar £3 10s., there remains £7 12s. I am glad to say I have mastered the art of driving and uniting swarms. I have put no less than seven swarms into one large hive, and they are taking down three pints of syrup a-day, and seem to be doing well. The weather is now beautiful, and the bees are gathering quantities of pollen and taking water from a tub placed near them with a float on the water.

I shall be obliged if the following questions be answered in your next issue:—1, Why do the bees in certain hives refuse syrup offered, whilst others take nearly two quarts in twenty-four hours? 2, Is it not unusual for drones to be flying about on fine days at this late season? 3, Does the appearance of drones at this time indicate that the queen is not fertile or that the hive is queenless?—HARDY-ON-THE-HILLS.

[Your correspondent has made a good beginning in an unfavourable season, and from the tone of his letters I venture to predict that his future career in bee-keeping will be bright and successful. In answer to his first question it may be said that the bees of some hives do not discover or find out the sugar or syrup that is placed on their hives. There may be some distance between the bee nest and the syrup which is not often travelled. In such cases some enticement is necessary. A trail or track of honey, or a bit of comb soaked in syrup and laid between the nest and food, will soon set the bees of any hive at work. No bees refuse syrup properly made and administered. Cold weather may prevent the bees from leaving their warm nest, and drive them back to it after they have begun to take syrup. The late Mr. Woodbury was astonished to find the bees of some weak hives chilled to death with honey in their hives. Our mode of feeding is from the board below the bees, and if some swarm hives are not full of combs their bees do not always come down for the syrup. In warm weather they never fail to take the syrup, but in cold weather some enticement or contri-

vance is resorted to. Our correspondent's second question touches the appearance of drones late in the season. It is unusual for drones to be flying about at the end of September, and their appearance at that time generally speaking is an indication that something is wrong—either that the bees are queenless or have an unfertile queen. There is good reason to suspect every hive that has drones in it now; but the existence of drones in some hives may be traceable to special treatment, and five years ago our bees and those of many other apiarists throughout England did not kill their drones till November. The hives that year were full of honey, and why they did not destroy the drones at the usual time I cannot tell. The non-destruction of drones that year till near Christmas was exceptional and extraordinary, for our bees were blest and happy with the presence of healthy fertile queens.—A. PETTIGREW.]

OUR LETTER BOX.

SUPERFETATION.—We have several communications on this subject, but we do not consider it suitable to our Journal.

DRESSING RABBIT SKINS (P. C.).—Take the skin as fresh as possible, and having mixed a sufficient quantity of salt and water till it will bear an egg, saturate it with alum; put the skin into this blood-warm, and let it lie and soak twenty-four hours; then take it out, and having tacked it upon a board (the fur inwards), scrape the skin, and a thin membrane will come off; then, having warmed up the pickle again, put the skin into it a second time, and let it remain five hours more; after which take it out and nail it upon a board to dry (fur inwards), and then rub it with pumice-stone and whiting. Hare and other skins may be prepared in the same way. They are always in best condition for preparing in the winter.

REMARKS.

3rd.—Fine morning, but rather hazy; very fine day and starlit night.
4th.—Grey morning and afternoon; fine forenoon, evening, and night.
5th.—Splendidly fine all day and night.
6th.—Rather hazy morning and early evening, otherwise a fine bright day; solar halo at 3 P.M.
7th.—Morning grey and hazy; fair all day, but not much sun.
8th.—Rain in early morning, but fair before 9 A.M., rain once or twice, but only in small quantities; fine evening.
9th.—Very fine morning, pleasant day, but rather deficient in sunshine; very slight shower in early afternoon.
Beautifully fine at times, and pleasant all through the week. Temperature slightly lower. Barometer very high.—G. J. SYMONS.

COVENT GARDEN MARKET.—OCTOBER 10.

We have very little alteration to quote. Business continues quiet. Large consignments of foreign goods are reaching us and are fetching lower prices. Hothouse Grapes are more than equal to the demand. Kent Cobs meet with a ready sale, prices tending upwards.

THE ROSE SEASON OF 1877—A RETROSPECT.

AS "WYLD SAVAGE" (who, by-the-by, is described in the "Journal des Roses" as "Mons. Wyld Savage") and others have written their opinions of the Rose season, I may perhaps as well add mine, especially as I have done so in previous years. My facilities for giving that opinion are about the same as usual. I have acted as judge in various parts of the kingdom, have visited many well-known Rose gardens, and have consequently seen Roses in the most varied aspects from their earliest blooming in pots to the last exhibition at which they were prominently brought forward—the Crystal Palace Show of September 21st, an unusually late date. I shall therefore record my views in just noticing a few points that the season has especially fixed on my mind.

1. "Has it been a good Rose year?" is a question that has been very frequently asked of me and others. My own opinion is that it has not been so, and I do not see how it could well be otherwise. The unusually mild winter which stimulated an exceedingly early growth and led in many cases to early pruning, the sharp early spring frosts which destroyed the young growth, the cold easterly winds that so long prevailed, the excessive wet in some places, all combined to frustrate the hopes of the rosarian; while the lateness of the season threw many out of their calculations in the matter of exhibiting. Doubtless grand, yea, magnificent blooms of Roses have been exhibited, but I do not call to mind any that have left a very marked impression on my mind; and I think it tells something for the zeal and skill with which Rose-culture is carried out in this country that, despite all these drawbacks, such Roses should have been generally exhibited as to have at all made the question a debatable one as to whether it was a good Rose or not.

2. It has been demonstrated, I think, that late pruning may be carried to excess. I will take my own Roses as an example. I had five beds of newly-planted dwarfs on the Manetti sent to me by Messrs. Cranston & Co. of Hereford, and Mr. Dickson of Newtonards, Co. Down, Ireland. They were admirable plants, vigorous and healthy, but the unusually mild winter stimulated them into early growth; not only leaves but buds made their appearance on the terminal shoots before I could prune them, and I at first thought when I did so that the lateness of the operation would in no way affect them. In this, however, I was greatly mistaken. I suppose that, being newly planted, they had too much to do below-ground to enable them to push out actively, and the consequence was that many of the shoots died back, others sent out short weakly growths of about 6 inches and have made no progress since; so that these beds, having also since then been attacked by orange fungus in a mild form, present rather a miserable appearance. I conclude that their being newly planted had something to do with it, because in those beds which have not been disturbed, although they were pruned at the same time,

the growth had not been hindered. In a visit I paid to my friend Mr. Baker's garden at Exeter I found the same thing—a fact which accounted, I think, for his failure in the cup class at the National, for on this piece of ground he had depended for success. They had been pruned late—as July 4th in ordinary seasons was late for Exeter Roses—and the result was precisely the same as in my own case; for whereas in the other parts of his garden his trees were marvels of growth and luxuriance, this quarter presented the same woe-begone aspect as my own. Hence the lesson one would have to learn from this is, that it is better when plants have been stimulated by a mild winter to run the risk of early pruning rather than defer it until a later period. By-the-by, what had better be done in such a case? I have an idea that it would be best to cut-back very hard to the old wood of last year, leaving about two or three eyes, and trusting to their shooting out low down, or even from underneath the ground, when the bud is inserted low.

3. It has, I think, demonstrated still further the excellence of the seedling Briar as a stock, especially for late blooms. I have elsewhere recorded the fineness of the blooms exhibited by Mr. Corp at Taunton on August 16th and at the Crystal Palace on September 21st, periods when it is not easy to find good blooms. In both these instances it is true that they were cut from maiden plants; but I understand from those who have grown them that they are also very fine from the cut-back plants. I heard so many persons expressing their determination to cultivate them largely that I am sure that this stock is increasing in popularity. With some, cuttings from the Briar find favour, the one drawback to the seedling Briar being that it takes so long to come to maturity that plants can hardly be sold so cheaply as those on the Manetti, and hence it is not a nurseryman's stock; but after awhile, when it comes to be more largely grown, perhaps this may be obviated.

4. It has been one of the most floriferous autumn seasons I have ever known. I know that someone has written about the Roseless autumn, but I cannot say that it has been my experience, and should imagine that it is very few localities to which this epithet would apply. Teas and Noisettes have been something wonderful. My plant of Rêve d'Or has been full of bloom, and has now (October 1st) a large number on it; while Hybrid Perpetuals have given me some excellent blooms, the principal being Baronne de Rothschild, Charles Lefebvre, Duke of Wellington, Capitaine Christy, Jules Margottin, Hippolyte Jamain, Dupuy-Jamain, Dr. Andry, and Baron Bonstetten. People sometimes sneer at the notion of Hybrid Perpetuals, but the difference is at once seen between such varieties and Paul Verdier and others which have been brought out as such, but which are simply summer Roses, never showing a second bloom. I may here mention that Mr. Noble's Queen of Bedders has with me well deserved the title; it is most free-growing, and I have never seen a shoot made yet without a bud at the end of it.

5. It has been a fine year for light-coloured Roses.

This one could hardly have anticipated, but as far as I have been able to form a judgment it is so. Certainly no Rose has come out so surprisingly as François Michelin. Wherever it has been exhibited it has been shown grandly, and has generally been chosen out as one of the finest, if not the very finest, blooms in the show. Other light Roses, such as Mons. Noman, Princess Mary of Cambridge, Comtesse de Serenyi, have done well, but it has exceeded them all; and it is one of the mysteries of Rose-growing why in particular seasons certain Roses seem to come out with such excellence. This is certainly the François Michelin year.

Such briefly is my record of the past season. Exceptional it has been without doubt, but Rose-growers have shown that no season thoroughly disappoints them, and when they can note some points of excellence in their favourites they take heart and go on with their culture in the firm hope in a good sense that "to-morrow (next season) shall be as this, and much more abundant."—D., Deal.

PLANTING FRUIT TREES.

AUTUMN has come again. Another season of growth is almost ended. Soon will the latest fruits be gathered and the fast-decaying foliage fallen; then, and often only then, comes the fruit-tree planter's opportunity before the soil, saturated by a winter's rainfall, has become sodden and cold. Mark this well, for success or failure in planting depends as much upon the time as upon the manner in which it is done. "PLOUGHBOY" would seem to be aware of this, for he has come to us now to assist him in finding a remedy, or rather a preventive, for the failure of fruit trees. He says, "Last year I planted in a marly soil a large quantity of fruit trees, and about half of them are dead," adding in the true national spirit, "I intend trying again." Well done, "PLOUGHBOY!" "Try again" is the motto which points to success, and gladly do we come to your aid.

Now there are two faults in a marly soil which require correction before it can become suitable for the growth of fruit, and these are its poverty and its power of retaining superabundant moisture. The remedy for the first is a heavy dressing of manure, and for the second drainage and a plentiful supply of coarse gritty matter, such as road scrapings, coal ashes, shattered bricks or stone chippings thoroughly mixed with the marl and manure, our object being to open up the soil to the action of the air as well as to drain and enrich it. It is of course desirable to treat the whole of the soil in this manner; but as this is a costly process it is customary to prepare stations for the trees, and to improve the condition of the remainder subsequently. Each station should be 6 feet square and 2½ feet deep, the bottom 6 inches being filled with broken stones rammed hard, and the 2 feet above filled with the prepared soil.

Drains of common 2-inch pipes should be made 30 feet apart and 4 feet deep, taking care to connect every station by a branch drain with the main nearest to it; for when stations are prepared in clay, or any substance of a compact adhesive nature, if they are undrained they become just so many death traps for the roots, owing to the accumulation of stagnant water. In my own practice I am not content to make a branch drain to the side of the station, but continue it right across the bottom, laying the row of pipes upon the hard-rammed stone. As a general rule it may be taken for granted, that when the soil in which fruit trees grow rests upon a deep compact subsoil drains will do good, but when the soil is shallow and has a substratum of rock, chalk, or shattered stone immediately beneath it (a natural drain), then of course artificial drains are uncalled for, and would, indeed, prove injurious.

Let the planting be done in November, pruning off all bruised roots, and shortening all leading shoots to about 9 inches. Do not bury the roots deeply, but keep them within 6 inches of the surface, spreading every one of them out carefully to its utmost length, treading the soil so that none of the roots lie at all loose in it. Cover the entire surface of the station with 3 inches of rough half-decayed manure immediately after planting, and fasten the tree securely with wire and stumps so that it may never be swayed by the wind, for if the roots and stem become loosened in the soil the tree will not grow and there is much risk of its dying. Always plant quickly, or cover the roots with soil when you receive them from the nursery. The effect of exposing the roots to the air is so pernicious that many a tree has been lost through it. Take care that the manure mixed with the soil is old and quite decayed,

or it may contain the spawn of fungi, which is also found in decaying wood and leaves, spreading thence over the roots of the tree and killing them.

Watch the trees carefully during the first season of growth after the planting. See that they do not suffer from drought. The surface-dressing of manure will act as a tolerable safeguard, but two or three thorough soakings of water or sewage are of material assistance to the growth and health of the tree in a dry season. See also that any fastenings of string or wire are loosened in time to prevent harm to the bark, which swells very fast upon a healthy strong-growing young tree.

Given healthy trees and due attention to these hints there ought not to be a single failure. Every point and detail mentioned is, however, of equal importance with the rest; and I must insist upon no negligence in any respect, for failures often arise from inattention to some matter apparently trivial in itself but of vital importance in its influence upon other things, and "PLOUGHBOY" will probably find that his lamentable failure was caused by inattention to some so-called trifle.—EDWARD LUCKHURST.

STORING POTATOES.

I THINK wherever it is possible the plan advocated by Mr. Luckhurst should be followed. I have proved the value of it, and so will others who practise it. The following is the results obtained here:—We will commence with the soil, which is very stiff and heavy, with a clay subsoil, undrained. We prepare our ground for Potatoes by rough digging or trenching in the winter, working-in all the manure we can procure. The sets are planted in drills 4 or 5 inches deep, 2½ feet between the drills, about the end of February or early in March. A mixture of soot, lime, and guano mixed with fine dry soil is sprinkled along the drills at the time of planting. The earlies are not planted so deep or wide between the drills, and are kept earthed-up as they appear above ground to protect from frost. The late sorts are not earthed-up at all. We use the prong hoe between the rows once, and keep clear of weeds. About the first or second week in August we keep a sharp look-out for the first appearance of the disease, and as soon as it is discovered the haulm is all taken-up without delay and removed off the ground. The crop is lifted as early as possible, ripe or not ripe. A great many people, I know, object to lifting before the skin is set, but if the ground is in good working order and the tubers come out clean, then by all means out with them, but be careful and not rub them more than you can help. We place them in a dry airy shed as thin as room will permit, and we always sprinkle a little slaked lime among them as they are emptied-out of the baskets. Out of fifteen sacks grown this season we have had only about one gallon diseased, and last year and the year before we had scarcely a diseased Potato. We grow Snowflake, Rivers' Early Ashleaf, Bresee's Prolific, Regents, Berkshire Kidneys, and Oxfordshire Kidney (which is the best late Potato I know), and Sutton's Red-skinned Flour-ball.—H. PLATON, *Bearsted Vicarage, Maidstone.*

THE ROSE ELECTION.—No. 3.

VOTES IN ELECTION.

In the first seven returns the Roses are placed in the order of merit—in twelve, twenty-four, and forty-eight varieties:—

Rev. C. P. PEACH, *Appleton-le-Street.*

GRAPES CRACKING.

In criticising the remarks of "A KITCHEN GARDENER," who had recommended leaving a portion of the top of the Vine to grow at will, Mr. W. Harris (see page 272) says he does not believe that the means adopted prevented the Grapes cracking, and he sums up the recommendation of another writer to take a portion of the foliage off the fruiting branches in a similar unceremonious way.

Now, it does seem strange at first sight that two very opposite proceedings should have a similar effect, but I hope to show that they are not so much in opposition as at first sight appears; and as I happen to be the other writer referred to I shall of course try to make my own point good, and will commence by telling Mr. Harris that his physiology is a little faulty when he believes that by taking a portion of foliage off he "would force more sap into them (the berries) and cause them to crack worse." All gardeners ought to know that the foliage has the power of attracting moisture and gases from the soil to a large extent, but that this power in the fruit itself is very limited. If you want a fruit to grow fast encourage plenty of foliage leading up to and beyond it; the channels of supply are enlarged thereby, and the communication is swifter. Any given branch of such a tractable plant as the Vine can be enlarged at will by bearing in mind this primary use of the foliage and regulating it accordingly. Again, not only does the foliage pump up the necessary elements for supplying the fruit, but at the same time as the foliage enlarges it causes the roots to act in harmony with it, and consequently to keep up an ever-increasing supply.

Although I do not covet large bunches of Grapes I have a great partiality for large berries and good finish, and as I know these cannot be had without ample foliage I do not stop the shoots in the orthodox way, but allow as much to grow as there is room for, especially after the commencement of stoning. Under these conditions and with liberal feeding any kind of Grape will be liable to crack if the Vine is not carrying a full crop; but the first cracked berry would be the signal for checking the growth by stopping the points or perhaps taking a few of the young growths off altogether, and the cure would be almost instantaneous. The only difficulty is to know how much to do, for there is a danger of overdoing it, and I pointed out last year that in dealing with a Madresfield Court Vine I took too much off, and the berries did not finish colouring nicely.

I follow the same system with Melons. Cashmere, which is grown largely, is very liable to crack just as it is ripening; but taking the foliage off beyond the fruit, and if necessary some of that leading up to it, will generally make all safe, and is a more certain method than strangling the stem.

So much for the denuding process. Now, how am I to reconcile it with "A KITCHEN GARDENER'S" of allowing the top to grow freely? Simply thus—the sap naturally flows most freely to the top at any time, and by stopping the side shoots in closely, while allowing the top to grow freely, it would of course more certainly take the main line, and the branches, especially those low down, would get little or nothing. At the same time if there were a bunch on the main rod I should not be surprised to see it cracked.—WILLIAM TAYLOR.

HAVING overcome the difficulty of growing Madresfield Court Grape without cracking, at least last year and this, I may, perhaps, be able to assist other cultivators who are troubled with their Grapes cracking. I have sent by rail a small bunch cut from a Vine with a heavy crop of bunches averaging in weight from 1 lb. to 4 lbs., and not a berry cracked on the Vine. The plan I adopt is this: As soon as I see the Grapes commence swelling after stoning I begin leaving on a

little air top and bottom all night, and keep on increasing the amount little by little till the cracking period arrives, by which time I have no trouble at all with ventilating, as I leave on just as much at night as I do in the day, and I manage to grow several of the leading varieties in this way, including Muscat of Alexandria, Muscat Hamburg, Madresfield Court, Black Hamburg, Lady Downe's, Alicante, and Frontignan. I might add I never use a syringe in any vinery, not even sprinkle a rod when they are breaking, although I have had from fifteen to twenty years' teaching to do so by several good Grape-growers. I provide all moisture required by sprinkling water on the floor of the house, and I am not troubled with red spider, as you will see by the leaves sent. No doubt the "fixed temperature" growers will disagree with what I say, but the proof of the pudding is in eating it; and I have two or three vineries yet with Grapes in, which I should not have the least hesitation to show any Grape-grower, grown with the wind blowing through the houses.—T. T., *Eastbourne*.

[The foliage sent is clean and healthy, the bunch of good form, not a berry cracked, and the bloom excellent.—Eds.]

COMPANY SHOWS.

BEING one of those who have always understood that the primary object of horticultural exhibitions is to benefit horticulture, I cannot but regret the tendency which is becoming established of societies selling themselves to public companies, gaining, it may be, a small immediate pecuniary advantage, but running the risk of humiliation, and not attaining in a certain and substantial manner the object desired. Some dissatisfaction has been expressed and much more felt at visitors having been excluded from the Aquarium Potato Show; but it must be remembered that the object of the Aquarium Managers was different from that of the Potato Show Committee. The desire of the promoters of the Show was to attract public interest towards their object, and this object a worthy one—namely, to foster improvement in Potato culture, and to encourage the production of superior varieties. The object of the Aquarium Company was to make money. They simply regard the Potato or any other society of a horticultural nature as means to that end: hence they bid for their prestige, buy them for the time being, and make the best of them. The matter of company shows is one which seriously requires to be considered; and I hope there is sufficient of the true horticultural spirit left to prevent the craft or science, call it what you like, with which so many are identified being made subservient to the purpose of any company who have no sympathy for an object beyond what they can extract from it for raising their dividends. I consider an alliance of horticulture and acrobats unseemly, unnatural, and incongruous. What do others say?—AN OLD EXHIBITOR.

THE ROSELESS AUTUMN.

BOTH Mr. D. T. Fish and Mr. W. Paul have publicly referred to the passing season as the Roseless autumn. Is it so? I, in common with most gardeners, dabble in a few Roses (my collection does not exceed four hundred), and with me in Surrey the supply has been abundant and the quality most excellent, especially with the darker varieties. I send you (October 1st) a dozen varieties, in order that you may see that we are not yet "Roseless"—viz., Madame Victor Verdier, Charles Le-fevre, Duke of Wellington, Mrs. Veitch, Victor Verdier, Madame Charles Crapelet, Sénateur Vaisse, Vicomte Vigier, Sir Joseph Paxton (from a wall of which I could cut many clusters), Madame Berard, Souvenir de la Malmaison, and the never-failing Gloire de Dijon; this latter will supply many blooms yet. As for the Old Monthly or China Rose, I can safely say there has not been such a profusion of bloom on them any time before this season. On Thursday, September 27th, I cut quite eighty blooms from my Perpetuals, and have been continually cutting since June, and judging from what I have seen there are many other places where Roses have been in glorious profusion. I am an utter stranger to the locality in which Mr. Fish lives, and the sunless autumn, together with the large amount of rain which has fallen in several parts of England, may have had much to do with the Rose's shortcomings in that situation; but with Mr. W. Paul the case is very different, and the corroboration of Mr. Fish's statement perfectly astounded me after seeing the extensive collections which have been voluntarily exhibited both at the Alexandra and Crystal Palaces, on September 13th and 21st respectively. At the

Alexandra Palace fourteen boxes, representing nearly 350 Roses, came from Messrs. Cranston & Co., Hereford; a great number also came from Messrs. Paul & Son, Cheshunt; others from Mr. Rumsey of Waltham Cross and Mr. Corp of Oxford, making on the whole a very extensive display. Was this an indication of scarceness? At the Crystal Palace there were collections from Messrs. Paul & Son, Mr. Turner, Mr. Cranston, Mr. Corp, and from Messrs. William Paul & Son. Was there any indication of a scarcity even on the 21st? On September 12th I was at Brighton. Messrs. Mitchell & Son staged forty-eight varieties in trebles; two other competitors also competed in this class. Teas were also numerous represented, not only by the trade, but by several amateurs. Altogether there were considerably over a thousand blooms exhibited, the majority of which, both nurserymen's and amateurs', were of very good quality.

With me the late frost during May did much damage to the forward buds, and a yellowish green caterpillar and the Rose maggot destroyed others, so that I had not such an influx at one time as I might otherwise have had, and possibly I have been repaid by a subsequent and unusually fine autumn display. Besides those sent Marquise de Castellane, La France, Baronne de Rothschild, and Madame and Marie Finger have been very fine during the present autumn.—J. W. MOORMAN.

[The blooms received were extremely fine, and at the exhibitions referred to Roses were exhibited in greater numbers and of better quality than we ever remember having seen at previous autumn shows.—Eds.]

NOTES ON MILDEW.

"HEREFORDSHIRE INCUMBENT'S" generalisms on mildew on pp. 263 and 264 contain a quotation which says that mildew is the result of a peculiar state of the atmosphere. As regards Vines in vineries I am of opinion that a close moist atmosphere will produce mildew. I believe this from two cases which have come under my own observation. In both cases close confined atmosphere started it, and when once the Vine mildew becomes established there is the risk of its spreading through every vinery, and may reach Vines also in other places in the vicinity of these affected. Proper ventilation of vineries is most important in order to prevent it. If it should make its appearance dusting the bunches or the house with salus is better than sulphur. It is lighter than sulphur, and if dusted on the bunches can easily be blown off again, and whenever it touches the mildew it destroys it, but although this is the case it still leaves the mark where the mildew has been.

Vine mildew is very different to the kind that affects the Rose and Peach tree, though no doubt the same kind of influences will generate either. Peach trees sometimes may only be affected in one or two cases in a garden, and the variety Royal George is a likely one to be affected. It may be considered singular how one Peach tree may be much affected with mildew and another beside it not touched. The probability is that the case would be different in a vinery, for as I have just noted, the mildew would go over the whole house. With Roses in pots in a Peach house I have observed that with want of ventilation the mildew soon makes its appearance and curls up and whitens the leaves of the Rose plants when the Peaches are not affected. This shows that Roses are more liable to mildew under a close atmosphere than Peach trees, being affected with it in an atmosphere in which Peaches are exempt.—R. M.

STRAWBERRIES.

No doubt Mr. Luckhurst is right in saying that Strawberries will grow in sound rich loam, but it is, nevertheless, a fact that some sorts will grow in such soil better than others. It is just possible that my experience as a cultivator of Strawberries is equal to that of your correspondent, and my success also may have nearly equalled his. I have tried, I think, all established varieties in cultivation, and have given such attention to the soil that my experience suggested was requisite, and I think, but of course I may be wrong in this point, that Mr. Luckhurst could not have done more. But after all I could do, La Constante, for instance, was comparatively worthless, while President was magnificent; Rivers' Eliza was very unsatisfactory, Sir Joseph Paxton was splendid; Amateur was only moderate, Lucas extremely fine; British Queen and Dr. Hogg I could also grow well. A mile from me was a clergyman's garden with soil of better staple than mine—

fresher and stronger. Runners from my fine Presidents produced insignificant crops in the rector's garden, while plants raised from my comparatively poor Amateurs yielded abundantly there, and La Constante was equally good when similarly removed. Would it not have been a mistake on the part of the rector and myself to have incurred both labour and expense in attempting to grow sorts which proved themselves unmanageable by local peculiarities, while we had other good varieties which flourished well with ordinary cultural care?—
A YORKSHIREMAN.

A PAPER FLOWER BASKET.

ALL who have a garden know how gratefully those not similarly circumstanced welcome the gift of a few flowers to take away with them. The difficulty is how to take them. They are either made up into a wisp and carried in a warm hand to wither and die, or else a basket is lent with the doubt, too

Fig. 58.—Pattern for Making Paper Flower Basket.

often a certainty, as to whether the owner will ever see it again. I send you herewith directions and a pattern by which anyone

Fig. 59.—Paper Flower Basket.

may in a few minutes make out of strong brown paper a basket that will answer the purpose, and concerning the returning of which there need be no questioning. My daughter has found such a basket very useful, and I have no doubt it will be a boon to many who wish to distribute their floral favours amongst their friends.

Instructions for Making the Basket.—Take a piece of brown paper 13 inches by 11, and fold it in five equal portions like

the pattern; then spread it open and fold in again where the dotted lines are, making the single fold the bottom, the double the sides; then lay it flat again—this time it will be divided in three pieces—and fold for the ends where the double dotted line is. Now take the two ends and bend them up to meet each other, folding the middle piece in at the ends according to dotted lines as shown there. One end will now fit in to the other, and must be secured by a few stitches. A strip of paper will be wanted for the handle 16 inches long, 4 or 5 wide; fold it four times and join underneath the basket, and secure it at the side in the same way as the basket. Of course the basket can be any size; these are simply right proportions.
—D., Deal.

JOTTINGS ABOUT PEARS IN THE NORTH.

THIS being the commencement of the planting season, what to plant is of importance, and it may be the more worth knowing when I state that of thirty-eight varieties of Pears eight of one variety were all that had any pretence to a crop, and many of these dropped midway in the season. That my remarks may be valued for just so much as they are worth, I may be permitted to state that, a little over two years ago a fine old pasture field of two and a quarter acres being offered for sale within a quarter of a mile of where my father for over thirty years laboured as a market gardener, I decided to throw up my trade as joiner and builder and commence the occupation more after my heart—a fruit-grower. I decided with hardy outdoor fruit to secure every variety recommended, and then at the earliest possible opportunity to reduce the number to only those which did best in the locality. This, as stated, found me last spring with the number of Pears named, and with the exception of Beurré de l'Assomption and Souvenir du Congrès, which I had only as maidens or trained, they were all well set with fruit buds. The third week in January threatened to see many of them in bloom, and the bloom would have been strong and promising. The third week in May found them in bloom, but blighted and miserable-looking; and seeing

that we had not the severe frosts in the county of Durham in May which there were in the south of England (my own glass never registering more than 5°), I attribute the failure here, not to frost but to the embryo blossom having perished during the great length of time it hung in the half-expanded state. When we had frost it was always after a dry day, but for weeks together we had little but rain, and rain, and clouds, and cold. I carefully, night after night, wrapped large sheets of paper around one and more trees of every variety; but the result was no perceptible difference between the covered and the uncovered trees. The most healthy-looking bloom was on eight trees of Pitmaston Duchess: it was not thickly set, but remarkably promising. The most miserable-looking were eight trees of Durandau, and on these trees every leaf perished; but singular, these were of the variety that set fruit, and they have also set a second crop, but, of course, of no value. What I bought for Alexandre Bivort is the third variety, but both last year and this the fruit has been smaller than I expected. Of over twenty trees of Louise Bonne of Jersey, and which is admitted to be one of the hardest, neither on my protected or unprotected trees had I a single fruit; neither had I one on eight and more trees of any of the following:—Baronne de Mello, Beurré Bachelier, Beurré d'Amanlis, Beurré Hardy, Beurré Superfin, Williams' Bon Chrétien, Maréchal de Cour, Doyenné du Comice, Joséphine de Malines, Madame Treyve or Olivier de Serres; one on Marie Louise, whilst of Marie Louise d'Uccle I have a fair crop. My Hesses even failed to set a fruit, but with them it was hardly a fair trial, and, judging by my neighbours' trees, my unhesitating opinion is that Marie Louise d'Uccle is as hard as the Hesse, and is destined

of first-class Pears to be the Pear of the north of England. One other thing is worthy of notice: Had the Pear crop in the north been ever so abundant it would have been next to valueless, as the fruit has grown to little more than half its usual size. The cold ground, through lack of sun, has undoubtedly prevented their swelling.—J. WITHERSPOON, *Chester-le-Street*.

Will anyone tell me his experience of the Pear Désiré Cornélis? It is highly spoken of in the "Fruit Manual," but I have never met with it. I tried last year to buy a tree or grafts, but failed. Neither Messrs. Rivers nor Mr. Smith of Worcester could supply me; I should like to know where I could procure it.

I for one should be very glad if now, at the commencement of the planting season, your correspondents would give us the benefit of their experience in the matter of Pears, stating, of course, their locality, and whether the Pears which they recommend or condemn (for this should be done as well as the former) are grown as standards or against a wall. There are some old favourites that succeed anywhere, and of course need not be mentioned—e.g., Jargonelle, Marie Louise, Winter Nelis, Seckle, Glou Morceau; but there are many kinds more recent or less known which may well deserve to be ranked with these. There is a certain pleasure in trying experiments, but life is too short to plant many varieties of Pears and then to be disappointed by them.

I can recommend Doyenné du Comice (pyramid), Bergamotte Esperen (wall, s.e.), and Joséphine de Malines (wall, s.e.), especially the latter, as quite first-rate. Louise Bonne of Jersey is inferior with me. Knight's Monarch will not ripen, nor Beurré Diel. Fondante d'Automne is good, so is Comte de Lamy and Thompson's. Beurré Bosc varies with the season. These (except Beurré Bosc) are grown as pyramids and standards.—L., *Cheshire*.

ORANGE CULTURE.

We cannot give you ("M. P.") better information than is contained in the following extracts from a paper written by Mr. Rivers and read at the International Horticultural Congress held in London in 1866, and which was published in the "Report of Proceedings":—"The difference," says Mr. Rivers, "between Oranges freshly gathered from the trees and the very finest imported is most remarkable; there is a crispness and fine aroma in Oranges freshly gathered difficult to realise unless they are promptly compared with imported fruit. They are indeed a luxury, and as such will be cultivated ere long in every good garden. The houses best adapted for their cultivation are the large span-roofed, 24 feet wide, 6 feet high at each side, and 15 feet high in the centre. A house of this size will require eight 4-inch hot-water pipes, four on each side, as artificial heat is required all the year to ripen Oranges in one season perfectly. A smaller span-roofed house, 5½ feet high at each side and 12 feet high in the centre, heated by four 4-inch hot-water pipes, two on each side, is almost as eligible for Orange culture as one of the larger size. A house of these dimensions, with a central path, and a border on each side planted with Orange trees, would form a pleasant and productive Orange garden; but to form an Orange grove, so as to have trees of fine growth and to give abundant crops, the large house must be resorted to. From the experience I have gained I firmly believe that no conservatory, no Orchid house, nor greenhouse, is half so beautiful or interesting as an Orange house constructed on the principles I now advocate, and provided with fixed roofs, rafters 24 inches apart, glazed with large pieces of glass, and admitting abundance of light, so that in December, when the trees are covered with their golden fruit and many of them showing their snow-white perfumed flowers, the scene is indeed enchanting, and is enhanced by the agreeable temperature, which need not be higher than from 50° to 60° Fahr. (10° to 15° Cent.) in cloudy weather. It is not frame heat in winter that ripening Oranges require, but an even agreeable temperature such as is experienced in the Azores during that season of the year. The houses above mentioned should have side ventilation as in Orchid houses—viz., an opening on each side of the large house 2 feet wide, for the smaller houses 1 foot wide; these openings should be in the centre of each side, and shutters of wood or sashes employed to close them, the latter of course being the most agreeable. The cultivation of dessert Oranges in pots or tubs is very simple. The compost they require consists of equal parts of peat, loam, and manure thoroughly decomposed; the

two former should not be sifted, but chopped up with the pieces of turf and roots so as to form a rough compost. The trees will grow in this freely and bear abundantly, but they should have gentle constant root heat. This is best given by enclosing hot-water pipes in a shallow chamber of bricks, and placing the pots on a flooring of slates or tiles forming the roof of the chamber. One of the most charming and prolific of dessert Oranges is the Tangierine; the tree has small leaves, and seldom attains a height of more than 7 feet even in North Africa. Its most valuable quality is its early ripening, so that in October, just as the late Peaches and other soft fruits are over, this luscious little fruit is ready for the dessert. And when freshly gathered no fruit can be more gratifying or delightful, as its aroma is so delicious and its juice so abundant, in this respect offering a pleasing contrast to those imported from Lisbon in November and December, the flesh of which is generally shrunk from the rind instead of being ready to burst as is the case with those plucked from the tree. They should, in common with all home-grown Oranges, be placed on the table with some leaves adhering to the stalks, thus showing that they have not made a voyage."

WHAT CONSTITUTES A GOOD EXAMPLE OF AN UNPROVED NEW GRAPE?

I NOTICED an announcement in the Journal stating that the prizes offered for the three single bunches of Golden Queen at the Crystal Palace were withheld, because they were not considered good enough. It appears that three prizes of £5, £2, and £1 respectively were offered by the raiser for the best three bunches, but these liberal prizes have failed to bring out more than three competitors, and none of the samples are considered excellent, and the prizes are withheld. The donor of the prizes and holder of the stock of the new Vine, while holding out the inducement to gardeners to buy his Vine and compete for his prizes, attaches no conditions, so far as I am aware, to his offer; but for all that, when the competitors come forward in good faith on their part they are told their samples are bad, and that they must go without the prizes. Is this fair and honourable, may I ask? and further, may I inquire by what standard of excellence as regards the Golden Queen were the three bunches judged? or, in other words, was it the fault of the growers, or the fault of the Grapes, that the bunches were in such "bad condition?" In my opinion the action of the Judges, or whoever was instrumental in withholding the prizes, has not improved the prospects of the Golden Queen. One can understand judges withholding a prize from a bad sample of Black Hamburgs or any other Grape of known excellence, but not in the case of a Grape that is on its trial for the first time; for I hold that it is no safe guarantee of its excellence generally that the raiser of the Grape may have produced fair samples of it himself. What new Grape, good, bad, or indifferent, that has been raised within the last twenty years has not been sent out as all that was excellent by the raiser, but which under general culture has perhaps turned out to be worthless? Permit me to say that I am not a disappointed exhibitor, nor was I at the show. I only gather my impressions from the reports.—A GRAPE-GROWER.

FLOWER GARDEN NOTES.—No. 1.

A COLD spring; spring flowers late in flowering and for the most part of short continuance. Primroses were an exception, flowering grandly, but bulbous plants though fine were soon over. The late frosts cut off to the ground such succulent plants as *Dieleytra spectabilis* and injured the flowering stems of *Spiræa japonica*.

Summer bedding plants were, owing to the cold during the early part of summer, planted out late, and in most instances in a backward condition. *Calceolarias* put out in April suffered severely, the frosts early in May cutting off many plants to the ground and damaging all more or less. They recovered, however, famously, breaking strongly from the stems, forming stocky plants by the early part of June. One-half of the plants—about a thousand—were at that time moved with good balls, well watered, all going well until the latter part of July, when a plant here and there showed by the flagging foliage evidence of disease. The disease appeared before the cold and wet, and continued its ravages with the rains. The infected plants wholly succumbed to the disease, the fungus attacking the stem at its junction with the soil or a little below, and destroying the plant root and branch. Though the disease

only showed itself in a few plants at first it spread rapidly, plants adjoining those infected were quickly contaminated; a diseased plant showing itself in a line or mass, when all or a majority of the plants in the infected line or mass became diseased. This disease is certainly contagious, for out of twelve detached lines or masses five only have no diseased plants. In no case is the fungus confined to the plants first showing evidence of its attacks, but has spread and is spreading (September 20th) to others. It is remarkable that the plants left where first planted have no disease, and the soil in which the diseased plants are growing is not nearly so heavily manured as that of the healthy plants.

Calceolarias are not much valued now-a-days, yet in their season and colour there is nothing to equal them, especially the yellows, in contrast with Perilla or Beet. We can have yellow foliage in place of yellow flowers, yet flowers are indispensable, none affording yellow so well as these.

Tagetes signata pumila has done grandly, growing finely and blooming profusely. Its colour is at best a dirty yellow though it is very useful, its foliage being so neat, the whole a dense close mass, and where *Calceolarias* do not succeed is a good substitute.

Lobelias have done well, and notwithstanding that we have a great many varieties of the *speciosa* section there is none better than the species when a true stock can be obtained, and the plants come quite true from seed, doing away with much labour and saving room for tenderer plants. Seedling plants endure drought much better than plants from cuttings, and flower more continuously to a later period.

Alternantheras have been a complete failure as they have ever been here, for though any amount of moisture is borne by them it must be accompanied with warmth, or the plants decrease instead of increase in size.

Succulents have enjoyed the wet, but the wet for weeks completely obliterated the hues of flowers; and ornamental-foliaged plants have grown well, except *Iresine*, which requires heat as well as wet. Beet was never, perhaps, finer nor better coloured.

Pelargoniums have been a failure, the best being *Waltham Seedling*, *Vesuvius*, and *Glow* in scarlets; *Master Christine* in pinks, though *Christine* has stood well, not going to seed as is its wont; and in whites, *White Clipper*. *Prince Silverwings*, *May Queen*, *Bright Star*, and for growth *Golden Circle*, have been good in the variegated section.

Flower gardening as I have seen and experienced it in the north has been a complete failure. What brightness there has been was afforded by foliage. Plants cultivated for their flowers have not done at all well. Notable exceptions are *Violas*, which have grown splendidly and bloomed freely; the masses of blue produced by *Blue Bell* and the yellow of *Lutea grandiflora* are really pleasing to behold in the midst of so much greenery, which no one need complain of this season as wanting to relieve the gorgeous glaring of flowering plants. Colour as afforded by flowers has been of a very meagre character; and though foliage colouring is all very well in its way, it is in seasons like this that soft hues and neutral tints need the richer glow of flowers to heighten their effect.—A.

NOTES AND GLEANINGS.

SIR HENRY SCUDAMORE STANHOPE, Bart., writes to us from Holme Lacy, Hereford, that the hurricane on the 14th inst. has done great damage:—"The fine old Tulip Tree is a perfect wreck, as well as the *Liquidamber* and *Deciduous Cypress*. The havoc among Oaks and Elms is dreadful; magnificent round trees are torn up by the roots in every direction, and damaged trees are innumerable. It will take a considerable time to clear the grounds of limbs and boughs." We regret this very much, for the trees referred to are, or were a week ago, grand ancestral ornaments.

—THE *LAPAGERIAS*, especially *L. alba*, now flowering on the roof of the entrance corridor in Messrs. Veitch's nursery at Chelsea, are highly worthy of inspection, as is also the large and healthy young stock of these deservedly popular climbers. Amongst the more notable plants now in beauty in the Orchid houses are several choice *Cypripediums*. *C. Sedeni* is proving its great decorative power, both by its exuberant growth and numerous and richly-coloured flowers. *C. Schlumii alba* is in lovely condition. *C. selligerum* is remarkably fine, as also are *C. uryandrum* and *C. Harrisianum*. The varieties raised in this nursery are not more noteworthy for their intrinsic beauty than for their free-growing and flowering properties.

Several other Orchids are also flowering. In the intermediate house the almost ever-flowering and ever-beautiful *Rhoddendron Taylora* attracts notice, and the incomparable collection of *Nepenthes*, *Cephalotes*, *Droseras*, and insectivorous plants are in superb condition. It is an advantage to cultivators that many of these extremely singular and withal beautiful plants are not by any means difficult to manage, and only require a comparatively cool temperature.

—THE WEATHER in the south of Scotland, a correspondent writes, has been very fine from the 6th of September to the 9th of October, when it came on very wet, and has continued showery ever since. The Corn crop is nearly all secured, but Potatoes in many places are not worth lifting owing to disease. Grapes coloured well during the month of fine weather.

—At last Mr. Bull's new *DRACENA GOLDIEANA* is announced for distribution. "Not distinct enough" is the verdict often passed on many new plants, but it cannot be applied to the plant in question. It is distinct, remarkable, and beautiful—a plant to be obtained and cherished by all who desire their collections of fine-foliaged plants to be in the greatest degree attractive and complete. It has contributed powerfully to Mr. Bull's success in the classes for new plants at the chief exhibitions at home and abroad. The effect of the collection at Chelsea, the broad fleshy foliage with zebra-like markings, is striking and unique. As seen in the condition in which it is produced at home none can dispute the novelty and great decorative excellence of this *Dracena*. A few attractive Orchids are now flowering, such as *Oncidium varicosum*, *Rogersii*, *tigrinum*, and *Marshallianum* (a large importation of the latter having been received, one variety of which is very distinct and fine), *Lælia marginata superba*, *Dendrobium formosum giganteum*, and *Odontoglossums*. A considerable addition is about being made to the nursery, Mr. Bull having purchased ground near to Cremorne whereon Messrs. J. Edmonds and Son, Lillie Bridge, Fulham, are about to erect eighteen span-roofed houses each 60 feet in length.

—LAST year attention was directed to the mode of growing *EUPHORBIA JACQUINÆFLORA* at Wimbledon House by planting a row of plants close to the back wall of the pit in which the Pines were plunged and training the *Euphorbias* to wires, thus forming a hedge reaching from the bed to the roof—a brilliant hedge it proved—at the back of the Pines. The same plan is adopted this year. A few of the old *Euphorbias* have been permitted to remain; but it is clear that young are better than old plants for this mode of culture, hence nearly all the plants now forming the hedge were struck from cuttings in the spring of this year. The plan adopted is altogether so valuable—yielding as it does thousands, even armfuls, of brilliant sprays during the winter without occupying space which could otherwise be employed—that it is recommended to all who have the means of carrying it out. Not the slightest harm is done to the Pine plants by planting the *Euphorbias* at the margin of the pit; indeed, the Pines, which are now planted out, are finer and more promising than ever. The visitor scarcely knows which to admire most—the sturdy and exuberant Pines or their remarkable background of *Euphorbias*.

—WE learn that Mr. F. Smith, late gardener to Lord Cloncurry, Lyons Hazelhatch, has been appointed gardener to Sir Charles Coote, Ballyfin House, Maryborough, Queen's County, Ireland.

—THE ORCHID HOUSE in the Victoria and Paradise Nurseries, Holloway, is now particularly bright and attractive. The plants in flower are *Lælia Perrini* (very fine), *Dayana*, *præstans* and *cinnabarina*; *Maxillaria nigrescens*; *Masdevallias ignea* and *Harryana*; *Dendrobium chrysanthum* and *formosum giganteum*, the flowers of the latter having continued fresh for upwards of six weeks; *Pleiones lagenaria*, *maculatum*, and *Wallichianum*, very beautiful; *Sophranites cernua*; *Saccolabium bigibbum*, a little gem; also *S. Blumei*; *Vandas Batemanii*, *suavis*, and *tricolor*; *Oncidium varicosum*, *Rogersii*, *crispum*, *pulvinatum*, and *tigrinum*; *Odontoglossums crispum*, *Reichenheimi*, *Lindleyanum*, and *grande*; *Cattleya Loddigesii*; *Aërides suavisimum*; *Cypripedium Harrisianum*; *Zygopetalum maxillare*; and *Warcewiczella quadrata*. The plants not in flower are also attractive by their cleanliness and excellent health.

—WHEN it is considered that a chief standard of excellence in a *DAHLIA* is the handsome form and entire doubleness of the flower it may savour almost of retrogression to recommend varieties with single flowers, yet we do not hesitate to speak strongly in favour of two single varieties (a yellow and a

scarlet) which have been flowering—indeed, are flowering still—in the nurseries of Messrs. Veitch at Chelsea. The effect of the two rows of plants is very striking, the thousands of small well-formed flowers imparting a distinct and attractive feature to the plants. The plants are dwarf (about 3 feet high) and bushy in habit; the foliage, like the flowers, is small. For beds or borders in pleasure grounds—for groups, such as large bed or lines in public parks—these single floriferous miniature Dahlias are especially suitable, and would afford an agreeable and attractive change from the double varieties—indeed, from all autumn-flowering plants. When a white variety is forthcoming a trio of great decorative value will be produced. The flowers when cut are excellent for vase, church, and festival decoration.

—The *Ontario Farmers' Advocate* recounts the following BENEFITS WHICH THE BIRDS ACCOMPLISH. The swallow, swift, and night-hawk are the guardians of the atmosphere; they check the increase of insects that otherwise would overload it. Woodpeckers, creepers, chickadees, &c., are the guardians of the trunks of trees. Warblers and flycatchers protect the foliage. Blackbirds, thrushes, crows, and larks protect the surface of the soil; snipe and woodcock the soil under the surface. Each tribe has its respective duties to perform in the economy of nature; and it is an undoubted fact that if birds were all swept from the earth man could not live upon it, vegetation would wither and die, insects would become so numerous that no living thing could withstand the attacks. The wholesale destruction occasioned by the grasshoppers which have lately devastated the West, is undoubtedly caused by the thinning-out of the birds, such as grouse, prairie hens, &c., which feed upon them. The great and inestimable good done to the farmer, gardener, and florist by birds is only becoming known by sad experience. Spare the birds and save your fruit. The little corn and fruit taken by them is more than compensated by the vast quantities of noxious insects destroyed. The long-persecuted crow has been found by actual experiment to do far more good by the vast quantity of grubs and insects he devours than the little harm he does in the few grains of corn he pulls up. He is one of the farmer's best friends.

—An American contemporary says that J. R. Young, jun., of Virginia is probably the largest STRAWBERRY GROWER in the world, he having picked this season 375,000 quarts from 135 acres of land, nine-tenths of which are of Wilson's Albany variety; 1700 pickers was the greatest number employed any one day. His average product is a fraction over 2000 quarts to the acre, yet the average crop of all the land cultivated in the vicinity was 1400 quarts per acre.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

FRITILLARIA DASYPHYLLA AND *F. ACMEPETALA*.—"These are two Fritillaries of which living plants have lately been brought for the first time from Asia Minor by Mr. Elwes, and liberally distributed. *F. dasyphylla* is a dwarf species, first gathered by Professor Edward Forbes, which belongs to the section with an entire style, and resembles in general habit *F. tulipifolia* of the Caucasus, figured "*Bot. Mag.*" tab. 5969. *F. acmepetala*, on the contrary, is a tall-growing plant, closely allied to *F. pyrenaica*, but with very different leaves. Both are plants of the mountains and perfectly hardy. *F. dasyphylla* was gathered by Mr. Elwes in light sandy soil between Moolah and Aidin, at an elevation of 2000 feet above sea level, and *F. acmepetala* in rocky woods in Caria."—(*Bot. Mag.*, t. 6321.)

ONCIDIUM EUXANTHINUM.—"A member of a small group of chiefly Brazilian Oncidia, of which the first described species is *O. bifolium*, a native of the Brazils, which differs in the racemose flowers, much smaller broadly obovate pseudobulbs, and shorter leaves. It is even nearer the *O. martianum* var. *bicolor*, *Lindl.* (*O. bicolor*, *Lindl.* in '*Bot. Reg.*' 1847, t. 66) in the racemose flowers, but that species has a solitary broad leaf, and very much narrower lateral lobes of the lip. Dr. Reichenbach describes the flowers of the original specimen as having greenish sepals and petals with brownish bars, but those of my specimens are of the same clear yellow as the lip, and the spots on the latter are of a clear red hue. The warts, &c., of the lip are not only variable in this genus, but most difficult to describe; in the present species they occupy a narrow area on the disk, and consist principally of a transverse row of tubercles and a prominent but small conical horn.

O. euxanthinum is a native of Brazil, whence it was imported by Messrs. Veitch."—(*Ibid.*, t. 6322.)

BUDDLEIA ASIATICA.—"A very common and graceful large shrub or small tree of Continental India, Burma, the Malay Peninsula, Cochin-China, and Java, advancing north-westwards to the Indus, ascending to 4000 feet in the Himalaya, and to 6000 in the Nilgherri Hills, but curiously enough absent from Ceylon. Two forms of it are common, differing much in the flowers, which are very variable in size and the length of the tube of the corolla; one form has a salver-shaped corolla, with orbicular spreading lobes; the other has much smaller flowers with short sub-erect corolla-lobes. The stamens in both are inserted near the mouth of the corolla-tube, not, as stated by Roxburgh, near its base.

"It is certainly remarkable that so very common, elegant, and sweet-scented a plant as this, which flowers for three months continuously in India, should not be in common cultivation; but it does not appear in the '*Hortus Kewensis*,' nor is it figured in any work published in England. For the specimen here described we are indebted to Messrs. Downie, Laird, and Co., who sent it in February, 1874."—(*Ibid.*, t. 6323.)

ALOE TRICOLOR.—"Perhaps it may be, as Mr. N. E. Brown has suggested, the *A. arabica* of which the foliage alone is described by Salmdyck (see *Kunth, Enum. vol. iv. p. 525*). But it is clearly not the plant originally named *arabica* by Lamarck, which is founded on the Arabian *A. variegata* of Forskahl. Our present plant flowered for the first time in the Kew collection this spring. We received it from the Oxford Botanic Garden, and they had it, labelled as a Cape species, from Mr. Justus Corderoy of Blewbury."—(*Ibid.*, t. 6324.)

MICROSTYLIS JOSEPHIANA.—"A very curious novelty, resembling a good deal the African genus *Lissochilus*, differing in size and habit from the majority of species of *Microstylis*, which are for the most part weedy green-flowered plants of no interest to the horticulturist. It is a native of the tropical forests of the Sikkim Himalaya, where, however, it escaped the notice of all observers previous to the late Dr. Anderson, F.L.S., then Superintendent of the Calcutta Botanical Garden, who discovered it in 1863, and sent plants to the Calcutta Garden. These flowered in April, 1867. It flowered at the Royal Gardens of Kew, in May of the present year, from plants sent by Mr. Gamnie, Superintendent of the Sikkim Cinchona Plantations, to whom the Gardens are indebted for numerous and very valuable contributions of Sikkim seeds and plants. It is named after the editor of this magazine in recognition of his services to orchidology when exploring, for the first time by any botanist, the primeval forests of the Sikkim Himalaya."—(*Ibid.*, t. 6325.)

ARTHROPODIUM NEO CALEDONICUM.—"This is a native of New Caledonia, recently introduced into cultivation by Messrs. Veitch. It is interesting geographically as extending to New Caledonia the range of another of the characteristic Australian and New Zealand genera. Its nearest ally is *A. candidum*, *Raoul*, of New Zealand, and the other five or six species besides these two are all confined to Australia and New Zealand. Whether it will be hardy about London still remains to be proved. The plant flowered with Messrs. Veitch in May, 1877."—(*Ibid.*, t. 6326.)

A ROSS-SHIRE TRADITION.

A TRADITION prevails in Ross-shire that it was foretold by the last preacher in a kirk at Loch Carron, now ruined, that after his death an unknown tree should spring up where his pulpit was, and that when it reached above the wall there should be a European war. A tree of which the like is not known in the neighbourhood has grown on the spot. This year for the first time the top is above the wall. I send you a sprig and berries. Can you tell me what tree it is?—J. BRODIE INNES.

[The tree is *Sambucus racemosa*, Red-berried Elder, introduced by Gerard in the year 1596. No genus has more superstitions connected with it than has the *Sambucus*.—*Ens.*]

CARPET BEDDING.

EMBOSSED bedding, jewel bedding, tapestry bedding, mosaic bedding, and artistic bedding are terms which have been applied to the more advanced types of garden decoration wherein low-growing plants remarkable for their striking habits and attractive foliage have been exclusively employed. There has, indeed been a general ransacking of the vocabu-

lary in searching for terms peculiarly descriptive of this mode of embellishment. It will suffice, however, to refer to it under the "old familiar name" of carpet bedding, leaving each to choose the special appellation he deems most appropriate.

Much has been written for and against this mode of garden ornamentation—some considering it not only as being the most advanced but the most excellent expression of decorative art, while others denounce it as being harsh, formal, and unnatural.

The mode of decoration adopted in gardens is simply a question of taste, and taste in flowers, as in dress, varies. If mistakes have been made in the arrangements of colours in the garden they have not been so numerous and so flagrant as to justify the system of carpet bedding being described by a contemporary as "glaring." Formal it is; indeed, formality is

its essence. If it is not formal (exact) it is nothing. But over-colouring has certainly not been the characteristic of those beds which during the present season have had the greatest share of public approval.

Carpet beds may be and are arranged in the most quiet of colours, of which the accompanying engraving from a photograph of the central bed in Mr. Ralli's garden at Clapham Park affords a sufficient example. When a bed is planted quite level—that is, in the true carpet style—a diagram affords a fair idea of its effect, but when the soil of one portion of the bed is depressed and another part elevated something more becomes necessary to enable the appearance of the bed to be adequately understood. It is not asserted that the illustration is of the best carpet bed ever seen, but it is submitted as one of the most distinct and pleasing that has been arranged in a

Fig. 60.—CARPET BED AT CLEVELAND HOUSE.

private garden. It is not a bed that is appropriate to any garden, nor are the means of every garden such as to enable this mode of embellishment being carried out successfully. It is submitted as an example of chasteness in colouring and excellence in execution, and also because the great majority of the plants employed in it are comparatively hardy. The planting of this bed has been described as follows by a visitor who inspected it in August:—Fancy a huge hollow and rather deep saucer-like dish 12 feet across with a rim a foot in diameter, and in the centre of this dish a raised mound, formed after the style of an inverted bowl, this mound being about 3 feet across the top and proportionately wider at the base, and about 3 feet high. Such is the ground-plan of the bed, and now for the mode of decoration. In the centre of the mound is an elegant specimen of *Dracaena indivisa*, rising from a circular base about 2½ feet in diameter of *Mesembryanthemum cordifolium* variegatum; this is surrounded with a ring 2 inches in diameter of the green *Sedum Lydium*, followed by a circle of *Echeveria secunda glauca*. Next comes a broad band about 8 inches wide of *Sedum glaucum*, in which at regular distances are richly berried clusters 6 inches across of *Nertera depressa*, each plant of *Nertera* being encircled with very small plants of *Echeveria secunda glauca*. Next comes a narrow belt round the mound of *Alternanthera amena*, margined with *Echeveria*. At intervals in this outer circle eight chains of the same plant descend down the sides of the mound, terminating in the lowest part of the bed—the "dish" of the

saucer, each chain encircling a miniature mound of succulents out of which springs a small plant of the silvery *Chamaepuce diacantha*. There remains now the groundwork decoration of this design—the whole interior of the saucer and sides of the central mound. It is simply planted and densely covered with the dwarf emerald green *Sedum* above mentioned. There is yet the rim of the saucer to be noticed. It is a foot or more in width and rather rounded. The inner and outer circles are *Echeveria secunda glauca*, next two narrow circles of *Alternanthera amena*, the centre of the rim being a band 6 inches wide of *Sedum glaucum*, dotted every 3 inches with small round plants of *Nertera depressa*. The bed is as striking in appearance as it is original in conception and artistic in execution. Every part is excellent, and, being chiefly of neutral colours enlivened with the brilliant bead-like clusters of *Nertera*, the more and the longer it is looked at the better it pleases.

The bed is a worthy example of carpet bedding and of Mr. Legg's taste.

THE POTATO DISEASE *versus* GAS LIME.—At p. 288 "W. G." says, "Dress your land well in December or January with gas lime, and you will have no disease." We make our own gas here, and have therefore plenty of gas lime. Last autumn one of the kitchen-garden quarters had a good dressing of it. This spring the same piece was planted with early Potatoes. When lifted not more than one in ten was free from disease.

I am not acquainted with anything that will prevent the Potato murrain in a wet season.—A KITCHEN GARDENER.

NIEREMBERGIAS AND THEIR CULTURE.

ELEGANCE of growth, pleasing habit, and chaste yet conspicuous flowers, are combined in the Nierembergias—qualities which certainly render them attractive, and also (since fashion now permits it) popular. During that period in English flower gardening known as the massing epoch many plants of quiet beauty passed into comparative obscurity and had to give place to others possessing qualities of a more imposing character—such as would add colour or grandeur to a formal

design. Since that time the public taste has changed, and not only changed but improved. Bright-coloured free-flowering plants can never be dispensed with for decorative purposes; but it is becoming more and more recognised that there are other and less gorgeous plants which are capable of contributing to the attractiveness of a garden. Amongst these are the Nierembergias—a small genus of plants allied to Petunias; they might indeed be almost regarded as miniature Petunias, both belonging to the same natural order, Solanaceæ.

The Nierembergias were named in honour of John Eusebius Nieremberg, a Spanish Jesuit, and author of a history of Nature. The species which is perhaps best known and most extensively cultivated is *N. gracilis*: it is a valuable edging

Fig. 61.—NIEREMBERGIA RIVULARIS.

plant for flower beds, and has been so employed effectively in Battersea Park during the present season. It is also highly attractive when grown in pots or baskets for greenhouse decoration. Plants taken up from the beds in autumn and potted flower early and profusely during the following season. Cuttings strike readily, and may be wintered in cold frames and protected in severe weather. *N. filicaulis* (lilac), and *N. calycina* (white), are also familiar, and are distinct and pleasing when cultivated in pots.

A species of more recent introduction and less seldom seen is *N. rivularis*. We are indebted to Mr. Ware of Tottenham for the accompanying illustration of this plant. It is also figured in the "Botanical Magazine," and is described as a beautiful little species, a native of La Plata, whence it was introduced by Messrs. Veitch of the Royal Exotic Nurseries, Chelsea, with whom it flowered in July, 1866. It was discovered by the late Mr. Tweedie upwards of thirty years ago. This collector describes it as a most lovely and fragrant plant, abound-

ing by the sides of the Plate river, and only within high-tide mark, its flowers rising above the dwarf grass which grows in similar situations in such profusion that the plant is discerned from a great distance. The flowers, which are yellowish-white, are sometimes tinged with rose colour. It roots freely from its slender stems. It is a charming sub-aquatic plant, suitable for cultivating in pots or in moist places in the flower garden during the summer.

OSBORNE HOUSE.

(AN AMERICAN HORTICULTURIST'S COMMENTARY.)

I HAVE mentioned the Queen's private residence at Osborne House in the Isle of Wight as one of the small but beautiful gardens with which England abounds. It was to me especially interesting, as showing how rapidly trees could be made to grow into beauty, or even utility if one were disposed to look on planting as a money investment alone. There are, of

course, many trees now which were growing on the estate when it belonged to Lady Isabella Blatchford, of whom Queen Victoria purchased it; but the major part of the trees now growing here were planted by Prince Albert or since his time, and numbers are over 50 feet high and 6 feet in circumference. Cedar of Lebanon, which we may with justice call a slow-growing tree, are many of them here over 40 feet high. A large number of our Californian Conifers, of which Prince Albert was very fond, are also of about the same height, and many of them I saw in great beauty for the first time. The *Cupressus macrocarpa*, for instance, here about 30 feet high, forms one of the most beautiful sights that a human eye could desire to look upon, and there are some very fine specimens of *Libocedrus decurrens*, which I may say here I find, all through England, "*Thuja gigantea*," though the error has been shown over and over again in American literature, and though anyone can see by the very look of the plant, if they were disposed to be inquisitive, that it is not a *Thuja* at all. If you ask them for *Libocedrus decurrens* they "do not know such a plant." The real *Thuja gigantea* they call *Thuja Craigiana*.

A very large number of the trees—enough to make quite an arboratum by themselves—have been planted at different times by celebrated or distinguished persons, as memorials of their visit to Osborne, or as commemorative of the birthdays of the Queen's family. The names of the planters and the occasions are neatly painted on "labels" at the foot of each tree. Some of these, like some of the planters, have had misfortune in their career and looked unhappy; but the majority were doing very well and must be a great source of pleasure. I envied especially the Princess Helena, who on May 25th, 1855, planted an *Abies bracteata* which was now 30 feet high. The branches lay flat on the ground, and the tree made a regular cone. These branches on the ground measured 55 feet round. The general appearance of the tree at a little distance reminded me of some of the beautiful Douglas Spruces I had seen in their native places of growth, but the leaves are very long, and I should judge a *Torreya* when old would look something like this. I wondered when I saw it whether in our own country we had in cultivation so pretty a specimen of our own native tree. The part where these trees are mostly growing is separated from the other parts of the ground by a dense hedge of Laurels and Laurustinus; and this makes a shelter from the stiff sea breeze very favourable to evergreen coniferous trees brought from our Pacific shores, though the hedge itself was planted to give a good landscape gardening effect to the grounds. There are some pretty specimens of our Mammoth Tree, *Sequoia gigantea*, on the grounds, and some that have suffered from the same disease which has not left us one good specimen in the Eastern Atlantic States, indeed hardly a specimen of any kind at all. Whenever I would ask the tree-growers of England or France about this disease they would answer that they knew nothing of it, and yet I saw traces of it everywhere in both countries. It is probably a species of *Æcidium*, a small parasitic fungus. It attacks the lowest and weakest branches first, and thrives best when the weather is warm. In our country with so much summer heat it progresses upwards rapidly enough to destroy the whole plant before winter sets in; but in these European instances it only browns some of the lowest branches, though in a few cases I saw half the tree destroyed. When I would call attention to it I would be told it was "only something in the soil," although a close neighbour, a little more shaded, perhaps, in the same "soil" would look quite sound.

There is a long avenue to the main road planted by Prince Albert with a double row of trees. The first is of *Araucaria imbricata*, the Chili Pine, alternating with Evergreen Oaks, and the back row of Cedars of Lebanon and Evergreen Oaks. There were thus three chances of some one doing well, so that the other two could be cut away in time. All have done well, and there has been nothing cut away yet. Our readers, of whom only a few have seen the *Araucaria* in greenhouses, can have no idea of the peculiar effect this tree has on the English landscape. It is quite hardy in that country, and we meet with it everywhere. Every garden has its beauty spots formed by some combinations or other; but I do not know that I saw a more beautiful piece of garden art in England than was here with an *Araucaria* for the chief centre. It was on a mound a few feet high, and behind the *Araucaria* were two beautiful specimens of the Californian *Cupressus macrocarpa*, the dark and feathery edge of which, seen on each side of the *Araucaria*, made a sort of perspective shadow to it, rounding it off, as it were, in a most beautiful manner. In the fore-

ground of the mound, and in front of the *Araucaria*, were pieces of fossil wood and rock, and in among them our *Yucca gloriosa*. Around the base of the little evergreen-crowned mound a narrow gravel walk swept, and on the other side of the walk, on each side, masses of *Yucca filamentosa*. The *Araucaria* itself has, as those who know it recognise, a sort of fossil-like look, and the *Yuccas* are scarcely less geological in their expression. The whole made a happy union and harmony such as we rarely see in landscape gardening. A seat was arranged where one could sit and enjoy this very pretty feature, as I did for some time. Those who know Queen Victoria tell me that she has a keen relish for natural beauty such as this. We often see trees, especially evergreens, clipped and sheared into many strange if not really hideous forms; but there is no tree-shearing on these grounds, except where some object is to be gained by it beyond the mere manufacture of a monstrosity. One of these usefully sheared plants is a Myrtle against a wall. This Myrtle covered the whole surface of the wall except the coping, and was sheared so close and regular that one might almost imagine a painter had wholly covered a board with green foliage. The whole was regularly about 8 inches deep.

In many parts of England the *Pyracantha* and *Cotoneaster* are grown against walls in the same way, and when kept thus neatly sheared are remarkably pretty—quite as much, if not often prettier, than Ivy. On a large heavy wall here our *Magnolia grandiflora* is grown and neatly trained. Of course this tree is "hardy" in England, but it mises our summer heats, and this wall treatment supplies some of this. Here, with its very sweet white flowers and fine evergreen leaves, it was very highly prized.

One of the matters which I have been struck everywhere in England, and which I find to prevail even here in this royal place, is the simplicity of the materials out of which the best garden effects are made. In front of some of the Queen's rooms is an extensive geometrical flower garden, made-up of numerous beds for flowers in masses, with gravel walks between. In many of these gardens the borders may be of Box; but here a narrow edge of what appeared to be costly stone surrounded each bed. The effect was very pretty; but a close examination showed the stone to be only painted wood. Near by is a very beautiful garden, made up in the grandest style, for in the centre is the celebrated Greek Slave, which, as a work of art, drew so much attention at the first and great World's Fair. The fountain basin is of polished granite; but soon after we pass out into real nature under an arbour of Roses and Vines. At a little distance is an alcove made in a terrace wall, and we are struck with the apparent richness of the work and the general choice appearance of everything in it. But as we get closer we see that the pretty flowers and foliage apparently carved-out are only sea-shells fastened on the wall in that way, and the whole washed with stone-coloured cement, and the massive ebony work is but polished coal. About these very artificial garden parts are, in excellent taste, the more artificial-looking plants, and the different kinds of Palm enter largely into the beautiful effects. Some of these Palms must be very valuable from their great size. Here, for instance, is a *Chamærops humilis* about 10 feet high, and with numerous young ones about it, so as to make a complete mass of Palm leaves. Though even the Orange grows here so well that there were some fruiting on the garden walls, it is thought best to protect the Palm in winter a little, and it is boarded over.

As I have said, the Queen prefers natural beauty to sheared trees, except when such shearing harmonises with artificial work, and in the square in which is one of the geometrical gardens are four sheared Bay trees in each of the four corners. They are of huge size, and here their effect is good. Leading down to the sea is also a wide gravel walk on each side of which are sheared Portugal Laurels, which also have a good effect. Around the palaces in Paris are huge Orange trees which have been kept in large square tubs for many years. They are all sheared, or rather trimmed with knives, so as to be all exactly of one size. If one could look along the top of a hundred of them in a line, no one would show a quarter of an inch higher than the others. These, during the summer, in France, are set out in their tubs alongside the walks at equal distances. But they cannot well have Oranges at Osborne; but they have Portugal Laurels in huge tubs, looking for all the world like these French Orange trees, as they are treated and placed in the same manner. But they appear grander, for the tubs in which they are growing are very much greater, and the trees are larger in every respect. But the secret is explained when the reader learns that the tubs are never

moved. The tree being hardy, remains there winter and summer; indeed the tubs have probably no bottom, and the Laurels are really growing in the ground. Yet these neatly-painted tubs with globes on the four upper corners give all the grandeur of the Versailles Orange trees; and what is of more consequence to an American and an Englishman, at very little cost for all! The piece of landscape gardening connected with this tub-Laurel-lined avenue is a masterpiece of good art. There appear to be only two or three acres on each side of the avenue, but while one is kept flat and smooth, and relieved only by the groups of Conifers and other artistic trees, the other side has a rolling contour of surface, and has massive groups of deciduous trees to match with the heavy swells of ground surface. Yet so well is the long straight walk carried through that no incongruity between the scenery on his right and his left strikes even the most critical.

Here, as everywhere, the aim in bedding is to have some carpeting unique, and not a copy of someone else's work. One might write a volume of what he sees in this respect, but it would be out of date by another year, as the object is to have new styles, as our ladies have new bonnets. In these grounds, coming to a place where some roads cross, there are beds in the angles in which the plants are arranged as playing cards. The hearts, clubs, and diamonds are outlined chiefly with a sort of Golden Stellaria, or perhaps it may be a Cerastium and Alternantheras. I remember, however, that the diamond was made of Echeveria for the outline of the character, and the filling-in was of Golden Pyrethrum.

The vegetable garden is not large, the Queen having most of the kitchen wants supplied from Windsor. What is grown, however, has to be of the very best character, and everything looked well. Those who think that pruning injures trees would especially be struck by the healthy appearance of the wall fruits, which are here of immense age, having been grown here before the Queen bought the place. A pruned plant, of course, never has a large stem. The Osage Orange in our country, unpruned, makes a large stout tree in a few years—in hedges, cut back, in twenty years is no stouter than one's wrist. So here in this garden we have Pear trees trained to the walls and pruned annually that were yet of very large size. I measured the stem of a Glou Morceau which was 3½ feet round.

OUR BORDER FLOWERS—COMPOSITES.

THE family is an extensive one, and though not possessed of the attractive properties that many of our favourites are, yet there is something about them that claims our attention. In the estimation of some they may be termed coarse. We admit that, but we think they ought not to be cast to one side because some will persist in saying they are ugly. They may not now be in such estimation as some of them have been in days long past. Some of them belong to our own land, therefore we note them the more pleasantly.

Elecampane (*Inula* (*Corvisartia*) *Helenium*) is a large showy British plant, in possession of medicinal properties esteemed as a tonic, and still retained in *materia medica*; it is also said that from this plant the Vin d'Aunée of the French is supplied. Its virtues have been extolled by the older naturalists, as Dioscorides and Pliny, but in modern days it has fallen into disuse; but the plant still retains its aromatic and stimulating properties useful in case of indigestion and nervous disorders, yielding its qualities to spirits more readily than to water. Few of this plant are seen in cultivation, being uncouth. Any out-of-the-way corner seems good enough for them when met with; they are at home in most situations, but they like light, air, and sunshine. They are not particular as to soil. Any ordinary free garden soil will meet their requirements; stagnant places are injurious. Some of them are strong growers and are the better for being staked, or they get blown about with the wind and become unsightly. They are easily increased by division in the spring or autumn.

Inula *Oculus-Christi* is very desirable, and with a little care may be made a very attractive plant. In a choice border its large, deep orange yellow, Aster-like flowers always attract attention when well grown. It is a capital plant for exhibition. *Inula* *crithmifolia* (Samphire-leaved *Inula*), is frequently vended for Samphire, to which it bears a very striking resemblance. *Inula* *dysenterica* is often met with by our waysides in out-of-the-way places, often in large quantities, cheering us in autumn. *I. saxatilis* is a dwarf kind, and is desirable as a rock plant where variety is sought after, useful alike for pot and indoors. *I. suaveolens* is a little coarse,

but worthy of cultivation for the pleasing perfume it emits. *I. grandiflora* is from the Caucasus, and ought to have a place in all shrubberies. Many others of this extensive family might be enumerated, but their being so little known, and I fear less cared for, they remain amongst the neglected ones.—VERITAS.

PROTECTION FOR FORCED PLANTS.

[THIS subject, on which "J. A., Birmingham," seeks information, is an important one, and is judiciously discussed as follows by Mr. W. Hinds in "The Gardener."]

It would be difficult to name any other subject connected with forcing houses that is more in need of general reform than the one which gives the title to this article. The value of proper means of protection before and after plants are forced cannot be over-estimated from either a cultural or a pecuniary point of view, because we cannot expect plants or shrubs of any sort that are exposed to sudden fluctuations of temperature to remain long in good health and vigour unless they are carefully tended and nursed for some considerable time after it has been necessary to remove them from the conservatory or show house. This being so, I should think that if the matter were intelligibly laid before any reasonable employer, little objection could be taken to a small outlay in providing such inexpensive places as would prove valuable auxiliaries to forcing houses. Both sides of the question should be stated clearly, in order that the idea might assume the character of a profit-and-loss account, which I think would tend to remove any misconception as to lavish expenditure. In the first place it would be necessary to run up the annual expenditure on plants for forcing, taking into account the length of time that intervenes between the date of forcing and the time when the same plants would have sufficiently recruited themselves to undergo another similar ordeal without the means referred to. It is generally supposed that forced plants and shrubs have reinvigorated themselves after a season's rest, so as to make them eligible subjects for a like purpose the following year; but I doubt the general accuracy of such a statement. True, there may be cases where this rule applies, but they are few and far between, and are only to be found where suitable structures are provided for completing and hardening the growth that is made under the cloudy skies of an ordinary English winter before they are turned out of doors. When proper pits, or temporary erections of some sort, are not obtainable, there is no other alternative left but to place such things in a warm sheltered corner out of doors, which is a poor substitute for a glass structure. It is here the comparison can be made, and it requires no expert at arithmetic to calculate the difference in value between two sets of plants treated respectively in the way I have described. Look at those early-forced Rhododendrons, Azaleas, Prunuses, Deutzias, &c., crammed together like so many oxen in a truck, with sickness depicted in every limb, and half-developed leaves scorched or starved into premature decay, or, at all events, rest; for we know that "sudden chills" impede the feeding or supplying power of plants, and once healthy action between root and branch ceases to exist we can no longer expect healthy development for a future day. Thus it is that a premature cessation of growth is forced upon plants, only to be removed when the weather becomes genial enough to excite the growing power which was not exhausted by natural means, but had been suddenly checked by the unnatural agency of cold. This is what is called second growth, which means a disorganised system of plant-growing, a system which is fraught with danger to the plants themselves as well as to those in charge of them.

Now, it is not wide of the mark to contend that those who build forcing houses in quantity have plenty of means to build auxiliaries to them; and I think I may further suggest that no more profitable investment can be made than in securing proper provision for the maintenance of health and durability in plants. Looking at the matter in a purely commercial light the question resolves itself into one of money either way. If there are no plant-protectors there are more plants required each year, in proportion to the inadequacy of the protection, and *vice versa*; so that in reality the employer who sanctions a small expense in this way is the gainer in a few years. Assuming for a moment that anyone was desirous of erecting one or two convenient places for this purpose, the following is a very good plan: After selecting a suitable piece of ground in some out-of-the-way place which is warm and well sheltered from winds, a foundation of bricks, level with the surface of the ground, should be laid for say one, two, or three span-roofed pits, the

proportions of which should be shaped according to the material at command. The sides of the pits may consist of thatched hurdles, which should be made to slide in a groove made in the sill which rests on the brickwork. Any old sashes of equal length can be prepared at a very slight expense, and a skeleton framework on which to lay them will merely cost a nominal sum. In this simple way useful plant-protectors can be erected, and the little outlay expended on them will be amply repaid in the health of forced plants, and in the neatness and general good order of a place.

Nothing imparts a more rubbishy appearance to Peach and orchard houses than a glut of such things strewn about here and there without any apparent system in arrangement.

Portable plant-pits of this description are not only useful for hardening-off plants that are forced, but they are also invaluable for bringing forward such things as Lilliums of all sorts, or, indeed, any hardy greenhouse plants. In the autumn, again, what a relief to better-class houses to have such places to bring forward Chrysanthemums—a class of plants that suffer more from early housing and insufficient ventilation than any other we could name; and lastly, we may notice that anyone in possession of two or three of those pits may prolong the season of Chrysanthemum flowers, and store away all pots that are required for stock.

NOTES ON VILLA AND SUBURBAN GARDENING.

THE weather has recently been favourable for forwarding all outdoor operations, especially the storing of roots. Beet must be lifted very carefully and stored without receiving any injury to the tap root, or it will lose its colour in boiling; also, instead of cutting the tops off close to the root, give them a twist round in the hands, and sufficient will break off. The weather has also been favourable for tying Lettuces and Endive for blanching, and for the removal of others to frames for protection. These should be lifted with good balls of soil and placed thickly in cold frames, from which frost and wet are excluded. Frequently stirring the ground is beneficial to Cabbages, Spinach, and other crops; it not only destroys the weeds which spring up at this season of the year, but adds materially to the well-doing of the crops. Young Cabbage and Lettuce quarters should frequently be searched for slugs and a grub that burrows under the ground and eats the plants off just at the collar; and all blanks should be made good as often as they occur.

Cauliflowers raised from seed sown about the end of August will require the protection of hand-lights or frames to render them safe throughout the winter. The plants are now about the proper size for transplanting. Hand-lights are most useful protectors; nine plants may be placed in each, and remain until spring, when those in the centre may be removed, leaving the four corner plants. These with liberal treatment afford useful early heads, and the others can be planted out in suitable quarters for succession.

Potatoes which have been stored should be occasionally looked over, as one decayed tuber speedily affects many others. Onions which are well dried should be stored thinly, or perhaps there is no better plan to preserve them than the old-fashioned one of "ropeing" them, which is work that can be done during wet days. Clear away Bean haulm and other decayed and useless vegetation, in order that the kitchen garden may be made as enjoyable as possible.

Flower gardens now require a regular transformation; the remains of the summer bedding plants which are not required for store purposes should be cleared away and thrown to the rubbish heap, and the edges of the beds be neatly trimmed, the beds manured and dug, and the spring-blooming plants planted with all possible dispatch to allow them to become well established before severe weather is upon us. Double Daisies, both white and red, Wallflowers, Polyanthus, Pansies, Forget-me-nots, and the various *Silenes* are amongst the more hardy and useful flowering spring annuals. The plants must have been specially prepared for this purpose as advised in former calendars, and should now be strong and well established. *Orocucos*, *Snowdrops*, double and single *Anemones*, *Turban Ranunculuses*, *Tulips*, and *Hyacinths* are also suitable for spring blooming, while many of the hardy *Sedums* (now so extensively used in summer carpet bedding) are also useful as edging plants; and seedling plants of the *Golden Feather* can also be advantageously employed. In planting bulbs it will be necessary to use *Crocuses* and *Snowdrops* as front lines or for the margins of the beds. *Tulips* and *Hyacinths* are taller, and should necessarily occupy the centres or back rows, as the case may be. Where spring flowers are not planted the beds can be made to present a very cheerful appearance by planting small hardy shrubs which have been kept in the reserve garden. Small plants of *Aucubas*, *Retinosporas*, *Cupressuses*, *Hollies*, *Portugal Laurels*, *Box*, *Ivy*, &c., are all suitable for this purpose.

Hybrid Perpetual and climbing *Roses* are now in good condition for making cuttings, and if the tops are taken off and cut in lengths of 6 to 9 inches and planted thickly in rows on a warm border most of them will root. Place the soil firmly around them, and protect them slightly in case of severe weather.

The grass will not require mowing frequently, but wormcasts and leaves will be troublesome for some time to come, and the lawns will require to be constantly swept and rolled; roll walks also, to make all firm and solid.

Greenhouses are now tolerably full. Care should be taken to ascertain that the *Azaleas* and other hardwooded plants lately taken under cover have not suffered by want of water. If the interior of the ball is dry a good soaking in a pail of water will save much after-trouble. *Richardias*, *Spireas*, *Lily of the Valley*, *Dieleytras*, and other early forcing plants require potting from the open ground, where they have been growing throughout the summer.

Chrysanthemums now require protection, for whilst the warm days and dewy nights are beneficial to them, frost may come any night and destroy all prominent flower buds, and it is possible we may have a taste of the equinoctial gales, which will destroy in one night perhaps that which has taken months to grow. *Chrysanthemums* are generally late this season, but the buds appear very plump and even, so that though they may not be in time for the earliest-fixed shows, we may expect some good blooms. All training of specimens, standards or pyramids, must be finished forthwith, or the foliage will not have time to resume its natural appearance. Continue to supply the plants liberally with liquid manure, for it is while they are swelling their buds that extra support is needed. An ounce of guano to a gallon of water will help them considerably.—J. W. MOORMAN.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

HARDY FRUIT GARDEN.

ON all the hardy trees the leaves have either attained the golden tinge of autumn or are rapidly doing so. Those in the open quarters fully exposed to the wind are speedily whirled off, but it is not so with *Peach*, *Nectarine*, *Cherry*, and other trees on the walls. If the leaves do not fall from such trees so rapidly as they ought a half-worn birch broom drawn gently up the branches will clear them off. See that all the branches are also nailed securely to the walls. We shall also look over all the trees in the open garden and do any pruning that is required. Trees grown on the dwarfing system are very apt to become overcrowded with wood, especially in light soils. It is very desirable that all superfluous wood should be cut out at the earliest opportunity. We do not find that the trees grow too much if the soil is heavy. Summer pruning is a good antidote for exuberant growth and deficiency of fruit buds, but we have found that in addition to this it is also necessary to prune the roots.

There are two objects to be attained by root-pruning: one is to cause the formation of fruit buds by checking the strong summer growth; the other is to stop canker should the trees show signs of this disease, which we fancy is caused by the roots running into unsuitable soil. In either case the object of the cultivator is to raise any descending roots nearer the surface, or, if this is not possible, to cut them, which will cause the formation of young fibrous roots; and if suitable fresh loam is placed round the roots they will spread laterally in all directions. We have sometimes, instead of cutting the roots all round the trees, done half of them one season and the other half the next. The check that the trees experience by having the whole done at one time deteriorates the crop for next season in some instances.

We shall as soon as possible go over the *Raspberry* quarter, and cut out all the old wood, and tie up the strongest growths which were made this season to the stakes where a stake is used for each stool. On one portion we have two wires strained, one above the other, to which the shoots are tied. This last plan is the best, as it allows the growths to be more regularly placed. It rather crowds the growths too much to tie up from four to six to a single upright stick; the other way they are arranged at regular intervals about a foot apart.

There are still a few of the trees from which the *Apples* and *Pears* have not yet been gathered, but we shall have them attended to very soon. The *Pears* that ought to ripen in October do not as yet show signs of doing so, and we fancy that some varieties will not ripen at all. The fruit is keeping very well that has already been gathered, except where it had been pecked by birds. They annoyed us very much this year, as not only *Pears* but a considerable portion of the crop of some sorts of *Apples* was damaged. Such sorts as *Cox's Pomona* and *Cellini* were the most attractive. We kept the birds from choice *Pears* on the wall by placing netting in front and fastening it securely at the top and bottom of the wall.

No delay should now occur in having plantations of *Strawberries* finished. If the work is not done this month the plants have but little chance to become established before the winter. We have kept the hoe at work between the rows of those plants

that were put out in August, the plants are now of large size and free from weeds.

Strawberry plants in pots are not unfrequently neglected at this season. If the roots become dusty-dry the plant does not show signs of distress, but it is a great mistake to allow the soil in the pot to get in this state. It is quite necessary to pay as careful attention to watering at this period of the year as during the summer. The soil has now become quite filled with roots and the ball of earth is very hard, and if from over-dryness the soil cracks away from the sides of the pots it is not easy to make it thoroughly wet again. If the plants are left out of doors until the end of this month and a wet period sets in, the best plan is to lay the pots on their sides to prevent the soil from becoming too much saturated. Laying them down also exposes the under sides of the leaves to the wet, which will destroy any red spider that may be on them.

CUCUMBER AND MELON HOUSES.

We have placed out the Cucumber plants, which will begin to bear next month, and continue to do so freely for the next twelve months if they are attended to and are not allowed to bear too heavily at any one time. We still grow Tender-and-True for winter, and have besides planted two sorts received from Mr. Kelway of Langport, Somerset. Mr. Kelway has succeeded in raising a strain of Cucumbers, evidently of the Blue Gown and Tender-and-True type; they are not only well adapted for exhibition, but are also good winter croppers. We explained our method of culture in the number for September 20th. It has been a very good season for the last few weeks for ripening Melons, and we have tasted green and scarlet-fleshed sorts of excellent quality. It has not been difficult to keep up the required temperature at night, and the sun has had a powerful influence by day. Fruit in a growing state or ripening must be treated to a temperature of 65° at night, and but little moisture is required from evaporation. Allow air by night as well as by day when the fruit is approaching the ripening stage.

GREENHOUSE AND CONSERVATORY.

These structures ought now to be kept very clean, and the flowers should be carefully preserved as long as possible, as they are very scarce at this season out of doors. Fading leaves are removed from Azaleas and many other greenhouse plants as they become tinged by decay. The house looks untidy if these are not removed; and further, as they may contain red spider and thrips they are better burned, or the insects may spread to other plants and cause very much more trouble afterwards. Zonal Pelargoniums are very useful plants at this time, but they have an untidy appearance if the decaying flowers in the centre of the trusses are not removed as soon as they are perceived.

The Chrysanthemums have been removed under glass, as we were afraid of the frosty nights injuring the blossoms which were showing colour; indeed, some of the early-flowering varieties, such as James Salter, have flowers very nearly expanded. As a preventive of mildew we throw a cloud of sulphur from the sulphurator, forcing it up amongst the branches, so that the largest portion of it adheres to the under sides of the leaves. Thrips and green fly also attack the young leaves and work into the petals of the flowers, causing much damage. These may both be destroyed by fumigating with tobacco smoke. The flower buds of Pompons may be tied into their proper position, and they should not be tied down too closely, as nothing looks more unnatural than to see the clusters of flowers jumbled together, while a well-trained specimen with the flowers evenly arranged and in their natural position—facing upwards, is a most beautiful object. No sticks are required for Pompons, but to grow the large-flowered varieties well it is necessary to have a stick for each flower, and when they are well grown and trained they make a fine show during the greater portion of November and December. It is well also to take note of the earliest and latest-flowering sorts. Mrs. G. Rundle, for instance, is sometimes in full beauty by the second week in November, and Lady Slade, Her Majesty, and other sorts of the same type will not be in flower until the last week in the same month. This very much prolongs the bloom. It is the same with the Japanese sorts; the earliest, James Salter, opens its flowers a month or six weeks before the latest, which with us is a noble golden yellow sort—Grandiflora.

Cinerarias and Calceolarias must now be attended to. The plants should be quite close to the glass, and they must also be protected from frost and damp. Their worst insect enemy is green fly, which seems to grow at a most rapid rate on the Calceolaria. Whether this is found on the leaves or not, the house should be fumigated with tobacco smoke to prevent its appearance altogether. Neither of these plants do well in a house where the atmosphere is very dry; they like a moist atmosphere, but it must not be so damp as to hang upon the leaves to cause mould on them.

FLORIST FLOWERS.

The work of the florist (the man who goes in for florist flowers thoroughly), is never done, and as the season wanes into autumn, and autumn gives place to the dull dark days of winter, there is sufficient to occupy all his spare time. Any time this month

the Carnations and Picotees may be potted and the Pinks planted out. Ours were done three weeks ago. It was necessary to pot the Carnations and Picotees to check their growth, else we do not care to pot them before the second week of this month. If they are potted too early the small pots become too full of roots before it is time to repot them in the spring. We would rather pot a second time later in the month to consolidate the growth. Greenfly continues to increase upon Auriculars, but we either fumigate or dust the leaves with tobacco powder. The larger outer leaves decay as the season advances, and we have them removed to prevent them from injuring the main stems.

The recent frosts have severely punished the Dahlias, and it is as well to dig them up on a fine day and to dry the tuberous roots in the sun, placing the stem downwards. This is necessary to drain out the water which frequently gathers in the hollow stem. The roots should be stored in a dry place and where no frost can reach them.—J. DOUGLAS.

TRADE CATALOGUES RECEIVED.

J. C. Wheeler & Sons, Kingsholm Nursery, Gloucester.—*Autumn Catalogue of Fruit Trees, Evergreens, and Roses.*

William Knight, Floral Nurseries, Hailsham, Sussex.—*Catalogue of Fruit Trees, Evergreens, Roses, &c.*

Souper et Notting, Luxembourg.—*General Catalogue of Roses.*

Joseph Schwartz, 43, Rue du Repos, Lyons, France.—*Catalogue of Roses.*

J. B. A. Delenil, au Haut de Rue Paradis, Marseilles, France.—*Special List of Amaryllides, Tuberous Begonias, Yuccas, &c.*

Rawlings Brothers, Old Church, Romford, Essex.—*Catalogue of Dahlias.*

Thomas S. Ware, Hale Farm Nurseries, Tottenham.—*Autumn Catalogue of Hardy Florists' Flowers and Roses.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (J. Sampson).—The title is "The Natural Principles of Landscape Gardening, or the Adornment of Land for Perpetual Beauty. By J. F. Johnson." Write to the publisher, C. Aitchison, 12, Castle Place, Belfast.

SEEDLING GERANIUMS (W. Swanson).—Your seedling Geraniums are not superior to others already in cultivation, and therefore would not be saleable as new varieties.

POTATO DISEASE.—"W. G." will oblige several correspondents if he will detail how and when he applied lime and gas lime so as to prevent the disease occurring.

LEAVES SPOTTING (An Old Reader).—Caused by defective root-action. The soil is not suitable probably, or water is applied judiciously. We cannot name Ferns that have no spores on the specimens.

VINES MILDEWED (R. B. R.).—If you remove the Vines to another house the mildew will be continued there unless it is previously extirpated by thorough dressings of sulphur.

NEWCASTLE SHOW (Hilton).—You must write to the exhibitors for the information.

CUCUMBER (J. B. A.).—Write to any of the principal seedsmen and tell them what you need. They will not willingly disappoint you.

BOXES (T. J. Harrison).—Write to Mr. Lovel, Weaverthorpe.

PRESERVING LEAVES (A Devonian).—Place them between sheets of blotting paper under a gentle pressure, and when quite dry stitch them on sheets of stout paper in a book of which each alternate leaf has been removed. Your bad specimens were not even numbered.

VIOLETS (R. J. S.).—We cannot without his permission publish the direction of "G. E. M."

LAMP-HEATING.—"H. C." asks for the experience and results of someone in heating by lamps.

BUDDLEA GLOBOSA (E. Y.).—It is a shrub, and usually grows to the height of 10 or 12 feet. It is a native of Chili. We have grown it luxuriantly on a chalky soil, and also on a gravelly soil.

SCALE (S.).—You will do well to destroy the Cotoneaster. Spirit of turpentine brushed over the branches would kill the insects.

STOVE (H. M.).—We cannot recommend any, never having used one. Write to the makers and ask for the name of someone who has tried their stove.

BON CHRÉTIEN PEAR (Croydon).—It was introduced long before the last century. Rea in his "Pomona," published in 1659, includes the Summer and Winter Bon Chrétien without any intimation that they were recent introductions. Dr. Hogg in the last edition of the "Fruit Manual," states that various opinions have been expressed as to the origin of the name of

Bon Chrétien, one of which is that François de Paul, the founder of the Minimes, being called to the Court of Louis XI. for the recovery of his health was styled by that Monarch "Le Bon Chrétien," and that he brought along with him from Calabria some of the fruit of the Pear now called Winter Bon Chrétien, which is said to be there grown in great quantity. Munting seriously affirms that the Pear appears to have received its name at the beginning of Christianity, and that from this title it merits the respect of all Christian gardeners. Another opinion is, that St. Martin, Bishop of Tours, was the first who obtained this variety, and that a king of France, having tasted it with him, asked, when it was presented to him, for *Des poires de ce Bon Chrétien*. But, perhaps, the most probable derivation is from the supposition, more or less well grounded, that it is the *Crustumum* of the Romans, but whether or not it is so is difficult to determine. Switzer says they are so called from not rotting at the heart, but beginning to decay from the exterior part.

MAGNOLIA (*T. H.*).—The leaf is of a Magnolia conspiciens. It is unusually large, but this is accounted for by rich soil and the climate of South Devon.

BULBS IN WATER (*J. G.*).—The best bulbs to grow in water are Hyacinths. By using cocoa-nut fibre as you propose Crocuses and Tulips will do pretty well. Mr. Barr of King Street, Covent Garden, has grown and flowered the "pretty sweet-scented Iris alata in a Hyacinth glass." Other bulbous or tuberous-rooted flowers may be tried in the same way.

PLANTING SPIREA JAPONICA AND NERTERA DEPRESSA (*Sambo*).—*Spiraea japonica* and *S. palmata* are quite hardy, though liable to have the foliage cut by severe late spring frosts. They should be planted in good rich light soil in a sheltered yet open situation from November to March in mild weather. *Nertera depressa* is hardy on moist rockwork in peat or vegetable soil in a sheltered situation, but is best wintered in a frame.

APPLYING CHARCOAL AND BONE DUST TO FLOWER BEDS (*Idem*).—Both are first-class manures. Charcoal may be used at the time of making the beds. A dressing 2 inches thick mixed with a foot depth of the surface soil is the most we have used to a strong soil, an inch thickness of charcoal and worked in with a fork would be a sufficient application to ordinary-textured loams. One peck of bone dust per rod (304 square yards) distributed over the surface and pointed in with a fork lightly prior to planting is very invigorating to most plants, notably *Pelargoniums* cultivated for their foliage.

CUTTING DOWN VARIEGATED RHODODENDRON (*Dan*).—Cut it down to the height required during moist weather at the close of April or early May. Propagation is very tardy from cuttings, but layers made now or in spring are certain to form plants quickly, the shoots being notched previously to being pegged in the ground.

BOUGAINVILLEA SPECTABILIS AND LÆLIA PURPUREA NOT FLOWERING (*Subscriber*).—The *Bougainvillea* should have the roots confined to a very limited space as compared with the extent of surface to be covered by the plant, and to be very sparingly watered after the growth becomes free, the object being to have the wood firm and well ripened. Watering should cease in August, only a little should occasionally be given to prevent excessive flagging, and the wood should be trained thinly so as to expose it fully to light and air. By keeping dry from August to March your plant ought to flower, pruning being restricted to thinning the shoots. The *Lælia* does not flower because we apprehend it is kept constantly growing, whereas it requires a plentiful supply of water and moisture until the growth is complete, and should then be kept dry and fully exposed to light, when it will flower in due course, provided the growths are sufficiently strong.

NAMES OF FRUITS (*Essex*).—Your Apple is *Gloria Mundi*. (*I. P. H.*).—We do not recognise your Pear. The deformities are not uncommon. (*J. D. Duffus*).—*Hawthornden*. (*Fitz*).—1 and 2, Not known; 3, *Dumelow's Seedling*; 4, *Gloria Mundi*; 5, *Wormsley Pippin*; 6, *Golden Winter Pearmain*. (*Northern Spy*).—1, *Winter Peach*; 2, *Wadhurst Pippin*; 3, *Rhode Island Greening*; 4, *Morris' Russet*; 5, *Pitmaston Golden Pippin*. (*Rev. R. Percy*).—*Lincoln Collin*. (*C. J. B.*).—*Cambusnethan Pippin*. (*Connaught Subscriber*).—*Yat*. (*W. H. Ashwin*).—1, *Gloria Mundi*; 2 and 3, *Winter Hawthornden*; 4, *Very like Golden Reinette*; 5, *Cobham*; 6, *Lewis's Incomparable*. (*G. F. B.*).—1, Not known; 2, *Duchess of Oldenburg*; 3, *Cellini*; 4, *Beauty of Kent*. (*J. Edge*).—*Northern Spy*. (*Sedgley*).—*Tower of Glamis*. (*R. B. L.*). 1, *Winter Peach*; 2, *Herefordshire Pearmain*; 3, *Dumelow's Seedling*; 4, Not known; 5, *Bedfordshire Foundling*; 6, *Baron Ward*. (*A Ten-years Subscriber*).—1, *Flower of Kent*; 2, *Winter Gilliflower*; 3, *Ord's*; 4, *Winter Colman*; 5, *Bedfordshire Foundling*; 6, *Bradrick's Nonpareil*.

NAMES OF PLANTS (*C. T.*).—*Viburnum Lantana*. (*Rev. T. A. B.*).—We have no plants on hand unnamed. Send some fresh specimens. (*A Subscriber*, *Andover and T. J.*).—*Viburnum Lantana*, the *Wayfaring Tree*. (*A. McDonald*).—*Tecoma radicans*. (*N. C.*).—Specimen of *Fuchsia* insufficient. (*Cycad*).—*Coccoloba platyclada*. (*Ten-years Subscriber*).—1, *Lycasteria formosa*; 2, *Erythrina crista-galli*. (*A. Y. D.*).—*Sedum spectabile*. (*T. Hyde*).—*White Beam* (*Pyrus Aria*). (*J. P.*).—*Duranta Plumieri*. (*G. B. C.*).—1, *Coccoloba platyclada*; 2, *Cystopteris fragilis*.

POULTRY, BEE, AND PIGEON OHRONIOLE.

TOUTING SHOWS.

THERE is a system very prevalent in the present day among the managers of poultry exhibitions which we consider very objectionable. The matter to which we refer is the plan of writing round to the chief exhibitors a day or two after the entries are supposed to have closed in the following way:—"Blankshire Show. Please send some entries! Open up to—." At present have only two Dark Drahma cocks and two ditto hens! Others proportionately weak. Hope you will help." This little note, generally written on a postcard, is then sent round to perhaps half a score of (for example) Dark Brahma breeders by the same post; and though it may be true that at the time they were sent only two entries had been made in those particular classes, generally most of the recipients of the postcard imagine on its arrival that they can get a prize very cheaply and so are constrained to send an entry, whereas by the fact of many thinking the same the class is frequently made

larger and the competition more severe than is usually the case. We maintain that if such a missive is sent to Mr. Jones it should be also stated that the Messrs. Brown, Smith, and Robinson also have had such an one, or else it appears to us to be obtaining entries on false pretences. We received such a card the other day, and have above copied it verbatim, only altering the name of the breed. And the fact of the system being worked as we have described was very vividly brought home to us, for a poultry fancier who was staying with us at the time, in the course of a post or two, had his letters forwarded from his home, and among the enclosures was a *fac-simile* of our own card; and he in his turn leaving us went to stay with a fresh poultry ally, and found to his surprise that he too had received just another card. This gentleman, however, very properly considers that equity should be the maxim of all shows, and as he did not like the idea of entries being obtained by these means he wrote to the writer, and remonstrated with him on the unfairness of writing in the same terms to so many without stating to each who else he had written to among exhibitors of the various classes. He also wrote to us in the following words, and his letter was a type of many such we have received. We quote from it:—"In my reply to the postcard, which I took some pains in wording, I said that had I intended exhibiting at Blankshire my entries would have been made in due course, and that I thought it very unfair to those exhibitors who had duly entered their birds that the lists should be kept open after the day originally fixed, and still worse that the Committee or Secretary should endeavour to swell the lists by informing a number of possible exhibitors of the classes in which there was likely to be little competition. I added that I was aware I was not the only exhibitor to whom a similar communication was addressed." The reply of the gentleman who sent about the cards was in the following terms:—"By dint of hard work and almost caddling for entries they have come up to more respectable numbers. I know it has become the custom to write round as I did to the well-known exhibitors if entries are short at the last moment, and if I had not found it to be the general practice from the oldest established shows down to the smallest local ones to do the same thing I might have hesitated to take such a course. It was done with no intention of deceiving anyone or drawing them in under false pretences, for surely there is no harm in striving to get up the strongest competition possible, especially when prospects look as gloomy as ours did, with only — entries on the evening of the date first announced for closing."

Against the practice there is this to be said—that those who make their entries at the proper time are not equally treated with those who are allowed to enter some days after the advertised date; for the first make their entries without knowing if certain birds of theirs will be ready by the time, while others by waiting do not enter unless their specimens are in a fit state, and so have the better chance; while if the date had been closed to all at one time, either all would have had to share alike in the uncertainty of the matter, or the first comers would have had the class to themselves and less competition against them. Again, against the touting principle many perhaps would not have entered because they had arranged for their birds to be on the day at some other exhibition, but on receiving the card imagine inferior birds will win in such small competition and so make their entries, whereas the similar cards being sent to many the class ends in being large and the chances for less valuable birds to win small. What should consequently be done is what the Secretary of an important show said to us the other day:—"Choose the last possible day before the show is held when entries can comfortably be received, and then publish that day and keep to it." Exhibitors will soon find out that the rule is observed and accordingly enter in time, which will stop all the necessity and consequent unpleasantness of the touting system.—W.

ALEXANDRA PALACE POULTRY SHOW.

THIS makes the third of the metropolitan shows for this season, and we are sorry that it has, on the whole, come off short in the number of its entries. This was, however, to be expected, for we never remember so large a number of important chicken exhibitions being held within so short a space of time in the early part of one season. We must, however, congratulate Mr. Nicholls on his admirable arrangements. The pens were all on one level, while the cards were placed on them as soon as each slip was handed in from the Judge. We were greatly pleased at this, and Mr. Nicholls has inaugurated, we hope, a commendable system for future shows. The Judges were—for poultry, Messrs. Mathews, Hewitt, and Teebay; and for Pigeons, Messrs. Equilant, Tegetmeier, and Capt. Heaton. We must content ourselves with noticing the chief objects of merit in each class, as the early date of going to press necessitates it. The quality of the birds was good, and many of the awards most judiciously made, while others, though under the same adjudicators, were much reversed from those of the Dairy Show last week.

Waterfowl mustered fairly, the Aylesburys and Rouens being both good collections, and the winners fine. In Blacks Mr. Kellaway walked his two pens in once more first and second, though Mr. Ogilvie made a good third with a pen very lustrous

THE PIGEON FANCY.

"Look! Do you see that flock of small Pigeons very high up just passing your strip of black cloud? Those are mine." "Yours!" "Yes mine. They are my Tumbler Pigeons taking their afternoon's aerial trip. They will alight here, and go in there to roost. There are six or eight young birds in the nests, and I will show you them up among the clouds with their parents if you will give me a call by-and-by. But just watch a minute; see every second or two one or other of them throws a single, double, or triple somersault, and they seem to vie with each other which will do those somersaults neatest and oftenest. Notice the one a little above the others. He is a Blue with barred wings and tail. See! he stands an instant on air, and there!—three turns at one roll, and he has not fallen much above a foot. Look again. Two somersaults and yet going upwards! He is a bird of remarkable power of wing, and always acts as leader of the flock." "Most extraordinary!" exclaimed my friend. "I never saw anything like that. Surely that is a curiosity in natural history. Is that tumbling not a disease?" "No; but could it be proved to be disease it is a most healthy one, as Tumbler Pigeons are the most hardy of all the family, and live to a good age." How big I felt then, when I could say those birds are mine—birds on the wing away among the clouds, soaring free as the wind, having all around them boundless space, and yet I could and did say they are mine.

"But come, I will show you something unique in the tumbling line amongst Pigeons. You see that pair of small red birds on the floor; stamp your foot. There! the cock with the white feather in the tail has risen but 2 feet and tumbled twice; and the hen (self-coloured) has risen only 12 inches and has tumbled once, both as neatly as the most accomplished Japanese tumbler." "Why is all this not generally known?" said my friend. "If it were known it would put a check on some of the wild theories now started." My reply was also in the form of a question. "Why do people walk over and trample down the most beautiful flowers and not know it? Answer, Because they won't look at what they are walking upon, and don't know of the world they live in." The above dialogue took place fully thirty-five years ago; it is no fiction, but what actually passed almost verbatim.

In those days the Pigeon fancy was carried out in all its entirety; all the varieties were kept pure—all we then had, which comprised all we now have excepting the Russian Trumpeter and African Owl. Of course I exclude the numerous Toys that come now and then from the Continent. At this late date we can still show a flight of Tumblers second to none, all colours, and still a pair at least that will tumble once for every 12 inches they rise from the floor or ground, and we still feel that it is something to be able to say to a friend who comes to see our flights of Tumblers in the clouds, Those birds are mine.

Without prejudice let us look at the state of the Pigeon fancy now. I may safely question, as a general rule, where is it? I go into the large towns of England—say, Liverpool, Manchester, Birmingham, and all the "black country," the very places in which the fancy might be carried to the highest points; but what do I see? At the breakfast and dinner hours perhaps from ten to fifteen flocks of Pigeons in view flying round and

round the chimney pots of the locality, so long as they are kept up by terror of the flag that is waved to keep them from alighting. These are no Tumblers, no! not anything of any merit. A lot of mongrels only fit to fly when pressed to it by the fear of some old rag, and the thing has become so disgusting that the magistrates of Walsall have determined to put a stop to Pigeon flying on the Sabbath, having already fined two men for prosecuting it. Certainly a move in the right direction. This is one of the fruits of the degeneracy of the fancy. It must not be supposed that I find fault with the particular fancy of anyone; I merely deplore the present state of matters, and would, if I could, turn the tide into the old channel when birds were bred to the original points without any innovations. When I used to start from my native city, Edinburgh, on my English journeys what a store of beauty awaited me! Newcastle on the one hand, and Carlisle on the other. South and farther south to London the sights were endless; Canaries predominated in this town and Pigeons in the next, and all as a rule were of high if not of the first-class order, and in the very Pigeon shops something could be bought worthy at the time of a better price than was asked. In those days the stocks exhibited to friends told at once of the artistic eye and elevated taste of their proprietors. The birds were kept for the pure love of the fancy, and therefore they must be of the highest order, not bred for the sordid love of gain, either by sale or for prize money to be obtained from shows. I hold that shows have done no good to the fancy, not because I do not approve of shows, but because I cannot approve of the manner in which they are conducted. But more of this shortly.

But what do I see now? Of course many of the old fanciers are gone; but alas! the fancy in a great measure seems to have gone with them. Here a stock of coarse birds, so-called English Owls; there a lot of Dragons; again a stock of birds, mere nondescripts called Antwerps; again the remains of the wreck of that beautiful bird the Jacobin. I am shown a bird which I cannot tell from what it has sprung, and am told "This is a sure winner." I am written to for birds, but "Don't send them unless they are certain winners." I can't see that anyone can ever be a true fancier who insists upon playing out the game of money in connection with the fancy.

Just look at our shows, particularly in England, what are they made up of? Long-faced, Medium-faced, and Short-faced Antwerps—in fact common flying Pigeons, Dragons of different colours, and so-called English Owls, all birds of no merit and bred without trouble. I see a show advertised to take place next month in the south, in which there are to be eighteen classes for Dragons, seven for Antwerps, and five for Owls: what interest can those birds have for the general public, or are they likely to attract an aspirant to the fancy? The fancy in the south is not only rapidly degenerating but seems to be in a moribund state. Over and over again I among others have appealed to our friends in the south to keep to birds having distinctive characteristics and to be done with all the cross-bred trash which are not worth a day's trouble or expense, and to come out in something genuine and worthy of their genius. But it seems of no avail, they will go on in their own course; and therefore I shall trouble no further, but turn to the fanciers of my native land, and appeal to them in connection with the trash that is so often seen, and say in almost the exact words of my ancient townsman Robert Ferguson—

"O Scotland that could once afford
To bang the pith o' Roman sword,
Winna your sons wi' joint accord
To battle speed,
Fight till the fancy be restored
Whilk now lies dead?"

—JAMES HUIE.

CANARY TREATMENT.

THE following advice of Mr. Barnesby relative to the management of a sick Canary which was infested with insects, and yet refused to wash except in its drinking fountain, having proved successful in restoring a favourite bird, may, perhaps, prove useful to others:—

"At once," advised Mr. Barnesby, "transfer the bird to another cage whilst you dress with either turpentine or naphtha the crevices of the one infested with the vermin. In about an hour's time scald and clean the cage with soap-and-soda suds. The following day the cage will be ready, but prior to placing the bird in let it undergo the washing operation, which can be performed in the following manner—One advantage is to get the bird washed as speedily as possible, and keeping it warm the whole of the time. You will require a cage for drying the bird in before the fire, with a cloth spread on the bottom of the cage. When holding a bird to wash it do so carefully but firmly. Place the bird in the left hand with its head towards your wrist and the tail over your forefinger. Do not press the thumb tightly across its neck or the feathers may become curled or frilled. Then with a soft shaving brush lather well down the back, wings, and tail. Turn the bird over and operate the same way about

the breast and underneath the tail. Wash the head and neck lastly, and when you find the dirt well extracted from the feathers rinse off in clean warm water, and dry with a soft cloth. Afterwards place the apparently prostrate bird in the drying cage, and in about fifteen or twenty minutes you will find the bird attempting to perch and shake and regulate its feathers. Let the water be about blood heat, and be careful the bird is not placed too close to the fire to dry. But even with all the above operations and precautions you may not at once get rid of the vermin, for around the very nail in the wall whereon the cage may hang the insects will secrete themselves, and this will show the necessity of further perseverance before the vermin are exterminated. Plenty of grit sand and bathing are necessary, and if your bird habituates itself to splash about in its drinking fountain it must be taught otherwise. No doubt you have noticed that when you have replenished the water fountain daily, the bird will take its bath such as it is. Instead of replacing the fountain open the cage door and hang on the entrance a proper kind of bathing vessel. The same may be purchased at a bird shop in London. The bird will thus gradually learn to drink and splash therein. After the regular bath is taken away replace the fountain."

The bird which was apparently approaching its end has now recovered its song, and is healthy and happy.—J. W.

THE USE OF PERFORATED ZINC IN SUPERING.

This zinc is made in sheets 6 feet long and a yard wide, and can be bought in this shape at a much cheaper rate than that charged for smaller quantities. The perforations are 5-24ths of an inch in diameter, which size permits the workers to pass to and from the supers, but excludes the drones and queens. I have this year employed it in seventeen hives, and in no instance was a super disfigured either by brood or pollen. I believe that this has not been invariably the case, as in the "British Bee-keepers' Journal" for September Mr. Abbott writes: "In some instances the comb (*i.e.*, the comb of sectional supers) has been filled with brood in most regular order, and in others some of the cells have had pollen deposited in them. This argues either that queens and bees differ in size respectively, and that one pattern of zinc will not suit all equally well, or that the bees and their queens are very wilful, for in the two sets of sections received from our honourable friend at Haverhill there was not a speck or blemish of either brood or pollen." Perhaps I may be permitted to suggest that one or more perforations in the zinc employed in the former case proved faulty in regard to size, and so admitted the queen and pollen-laden bees. I found a piece of zinc in this state, having four holes ragged and elongated, which would certainly have given a passage to a small queen if I had used it. At the Alexandra Show last year I saw the zinc was employed in some cases simply by laying a sheet cut the same size as the top of the hive upon the frames, the supers being placed upon it.

My method of using it is as follows:—I fix the sheet of zinc to a frame formed of quarter-inch wood 1 inch broad, and having a piece running across it parallel to the bars of the frames to support the zinc in the middle. I remove the quilt, and the framework occupies its place. Over each half of the sheet a set of sectional supers can be placed. I only place one set at first, keeping the opposite side covered with a piece of carpet until the first super has been commenced, then a second super is given. When one super is finished I take out with a penknife two slits of wood from its top and place a second super over. The bees soon ascend if honey is being collected, and as soon as the upper one is well under weigh I withdraw the lower one, the upper one taking its place, and so on to the end of the season. The framework upon which the zinc rests allows the space of a quarter of an inch above the frame bars, and thus gives free entrance from any part of the hive to the supers. Two accidents occurred to me this season in connection with the use of the perforated zinc. On May 14th a stock which was unusually powerful, and which was bringing in honey from fruit trees, seemed ready to enter a super. I was much engaged at the time, and placed a set of sections upon the quilt, giving access to it through the central feeding hole. This super remained so for about a week, the bees building several sections of comb, when I substituted the zinc and framework for the quilt and placed the super in its proper position at one side of the top of the hive. The super was rapidly filled and another at its side. Two others were entered above them, and according to my usual plan I proceeded to remove the lower supers. I then found that the bees refused to vacate the first super, and upon examination I found that her majesty was located therein and that the four central sections were full of brood and eggs. I first ascertained that all was worker comb (I did not wish to have a heap of dead drones on the zinc), and I then determined that during the glut of honey which had set in I would prevent the queen from again entering the hive, detaining her a prisoner in the super. That particular hive gave me the greatest produce

of honey of all the hives in my apiary excepting one. When the harvest began to fail I released the royal captive, having first examined the stock hive, which, as I expected, was stored with honey from side to side. Several combs were extracted, to be employed in hives to receive driven bees this month. Empty combs were put in their places. Gentle feeding commenced, and now that hive has a teeming population and plenty of stores for winter consumption.

The other hive alluded to above contains the queen which headed the colony in the straw skep last year, and which produced 131½ lbs. of surplus honey shown at the Alexandra Show. This queen having proved to be so valuable, and being likewise a young one, I determined should not be prevented for want of room from producing as numerous a colony as care and her "natural abilities" could compass. I think I stated last autumn that I had transferred her and the bees and combs to a bar-frame hive, having room in it for sixteen frames. I constructed this hive with a particular purpose. During the winter the eight central frames only were tenanted by the bees, wooden partitions of a quarter-of-an-inch stuff parting off the four outer frames at either end from the central ones. I spared no pains to induce the queen to lay eggs early, and the month of April showed me that in spite of the unpropitious spring the eight central frames were covered with bees and full of brood in all stages. I then gave two more frames to the brood nest by moving the two partitions back and exposing a frame at each end respectively. These frames were provided with clean old worker comb. The honey harvest commenced. The hive was full of bees, and now I carried out my design. A Lee's Crystal Palace super was first given over zinc at the top, covering the ten frames. This was entered, and when well begun I moved the wooden partitions, this time not only placing them respectively a frame back, but substituting for them two sheets of perforated zinc. The frames exposed were guided with wax midribs, and could be reached only through the zinc perforations. I believe that the bees would have swarmed that day, but that the extra collateral space prevented them from doing so. Strips of half-inch wood resting on the rebates shut off the passage to the side spaces from above. I found that the bees still increased, and that a glut of honey had set in; I therefore removed the wooden partitions altogether, and although the harvest ended so suddenly and prematurely, I found the whole of the six frames, three at each end of the hive, stored and sealed, not a speck of pollen and not a trace of brood visible on them. Weight 81 lbs., a Lee's super 22 lbs., and a set of sectionals over the Lee's 18½ lbs.; total of virgin honey, 71½ lbs. I was quite contented with this considering the season, and I think I have learnt a new method of employing the zinc, together with the use of the dummies or wooden partitions.

Many interesting experiments have been made by some of our leading bee masters during the past season similar in some respects to the one I proposed to myself and carried out, but all differ somewhat from the method I have attempted to describe. My desire was to give to the bees, at the same time that super room was being slowly augmented, gradually enlarged collateral space, and I believe that in a good honey season the results I obtained could be more than doubled in value by removing the frames from the sides one by one as they are completed and replacing them by others with deep sheets of midribs. My letter has been spun out to such a length that I cannot ask for more space to give your readers my experience—my first year's experience of Ligurians; this I shall hope to do on a future occasion.—P. H. PHILLIPS, *Offley Lodge, near Hitchin.*

BEEs IN THE YEAR 1877.

THE bee season of 1877 will long be remembered by apiarians as being one of the worst experienced for a considerable number of years—for over two decades at least. In looking back over its course I can scarcely find one redeeming point from its opening to its close. Its disastrous history may be read in the mortality of hundreds of hives throughout the country; indeed, in the utter ruin and extinction of whole apiaries. I do not know if matters are so bad in the south, in the more genial climate of England, where comparatively better weather apparently prevailed; but in Scotland, more especially in the eastern, central, and northern portions of the country, the havoc produced in many apiaries is unprecedented.

My own experience of the present bee season may, perhaps, in some measure represent that of many other bee-keepers. The autumn of 1876 found our hives generally well stored with provisions and amply populated. The wintering was extremely favourable. No lengthened confinement occurred to injure health or diminish unduly the population of the strong and healthy stocks. The opening spring accordingly found hives generally in splendid condition. Breeding, too, commenced very early, and everything promised well so far. February and March, however, were cold and backward, and scarcely a pollen load was seen to enter many hives for days together. April was not much better. Breeding evidently became completely

checked, and the bees accordingly diminished rather than increased in all hives. There was an improvement in May, and things began to assume a more hopeful aspect. June, too, with not a few good days succeeded, but all hives were far back for the season. The population in any hive was not such as it should be in this the great swarming month in Scotland. Swarms issued freely enough in the earlier localities, but the young colonies were comparatively small. In the later districts, however, bad weather prevented in many cases swarming altogether, and there were few after-swarms anywhere. For a time things went on hopefully yet slowly, but the season was now far advanced, and unless really good weather set in during July there would be little or no flower honey. Alternate good and bad days occurred, but swarms failed to fill their hives even with comb in the usual time, and little or no honey was being collected beyond the temporary wants of the moment. It now became evident that there would be no surplus flower honey. The supers were taken possession of, but little progress was made in working in them. Any little honey that was collected and stored there was afterwards speedily removed and utilised for the more pressing wants of the community. Now came the white clover season, but it miserably failed. This flower, second only to the heath in productiveness of sweets, was from the character of the weather unvisited by the bees, and so, too, may it be said in some measure of the wild mustard and bean, both highly prized by bees: little or nothing was obtained from them. Thus all the principal honey-yielding flowers of summer completely failed from wet, windy, and unseasonable weather. One hope still remained. The heath was yet a resource left, but it would be two weeks late at least. Meantime the hives were being fed to keep them up to the mark. Notwithstanding every effort, however, it was apparent the hives were fast diminishing in population onwards to the middle of August, when to the moors they were sent as the last resource left. I long hesitated. The weather was still doubtful; indeed throughout the season a sort of chronic sameness prevailed, so that if a few good days occurred these were succeeded by the recurrence of wet, cold, and sunless weather. No sooner had the hives been pitched down in the moors, therefore, when it became too evident that the movement was a mistake. There was no change in the character of the weather, and, to crown all, the heath blossom itself was defective, and even in the scanty flowers there was little or no nectar secreted. Thus after a three-weeks visit to the moors the hives were brought back in a worse state than when they were sent. Feeding even had to be resorted to at the moors to ward off starvation, a circumstance unprecedented in my experience. I counted some eight hives around my own that had completely succumbed, and during a subsequent visit I witnessed that ill-omened phenomenon, a hunger swarm, issue from some starving hive and settle upon one of my own hives. Considerable massacre was the consequence, as these are not the kind of accessions—a starving population—any hive is disposed to receive with favour. The poor queen was shortly afterwards found cast out dead.

But failure in honey-gathering is not the only evil of this most disastrous season. Most hives are sadly deficient in bees, and an examination of some will show that much of the combs are filled with unhatched brood, famine-reduced population combined, producing a state of matters very undesirable in any hive—namely, combs filled with sealed dead brood. Nor is this all the bad results of this untoward season. Not a few young queens have failed to become fertile from long-continued inauspicious weather. No less than five cases of this kind occurred in my own apiary. Such hives accordingly found at this season in such a condition are almost worthless, for though supplied with fertile queens they can never sufficiently recover or become good keeping stocks, as all the bees are adults, two or three months old, and cannot perhaps see, far less outlive, the winter.

Such is the sad experience I have to record of the present bee season, and I would accordingly advise that all hives be thoroughly examined, and their wants and deficiencies supplied as well in regard to food and population as to the state of the brood combs.—J. LOWE, *Edinburgh*.

BEE GOSSIP.

I HAVE given my hives this autumn nearly 1 cwt. of sugar, or about 170 lbs. of syrup. As I have only fed seven of them it will be seen that the average given to each stock has been about 24 lbs. This large quantity, however, makes but a poor show in several of the hives (although they are probably well enough supplied for the winter), because the bees were in general so utterly impoverished that they had nothing whatever to live upon, hence they had to support themselves and their brood from the provision with which my not unselfish bounty had supplied them.

For five or six weeks in August and early September the food was taken down with great regularity and in considerable quantities every day, but no hive took down more than 2 lbs. in

the day. All this time there was more or less of breeding going on in each hive. Latterly, however, but little food has been taken down, although the weather has been very warm by day with plenty of sunshine. It seems as if the bees had suddenly tired of it. Is it that September is a rest month with them, or that there being nothing to tempt them out into the fields they have fallen into a semi-torpid state and have not that stimulus to their energy which an actively foraging stock always finds when honey is to be found abroad? I am, nevertheless, daily expecting to witness a change, as the ivy blossoms are beginning to expand and will soon be full of honey and pollen if the weather permits. Then I expect to find, simultaneously with the waking-up of the bees' activity in the fields, a correspondingly renewed activity in emptying my feeding bottles.

The nights are unusually cold now, even within five miles of the Bristol Channel, and on low ground, and my bees begin to shrink within their combs and cells, so enabling me to see the condition of their stores. All look healthy and comfortable and seem ready for what may come, but soon I shall begin to cover and swathe them in drugget coats and blankets, that they may feel as little as may be the vicissitudes of weather, be it hot or cold. When once bees are wintered they should be kept still and quiet as much as possible. The quieter they are kept in a moderate and equable temperature the more successfully and with a lesser consumption of honey will they pass the December quarter. So no more feeding till the month of March.

All entrances should be narrowed to a size sufficient for four bees to pass in at a time; if larger, cold winds will enter with the more deadly effect, not to speak of various enemies which are now hunting about for winter quarters as well as for plunder. Drifting snow, too, must be carefully guarded against; it penetrates every crevice, and should be swept away continually as being among the deadliest of pests to our apiaries.—B. & W.

OUR LETTER BOX.

OXFORD POULTRY SHOW.—The entries are, of poultry 1013, and of Pigeons 1070.

REMARKS.

- 10th.—Rather hazy forenoon, dull but dry all day; wind rising at night.
 11th.—Rain during the night, followed by a very fine day; windy at night.
 12th.—Very fine all day, but rain at night.
 13th.—Wind and rain during the night and in the morning; a dull day, with a slight shower about 5 p.m. and very dark; starlit night.
 14th.—Beautifully fine all day, and starlight at 9 p.m.; but before midnight the wind rose rapidly, and by 1 a.m. it was terrific, and so continued till nearly 9 a.m.; rain fell about 6 a.m.
 15th.—Wind and rain at 9 a.m., but soon becoming bright and fine, though windy, all the forenoon; afternoon less bright; evening fine, but wind very high soon after midnight and during the early morning.
 16th.—Rather a dull day, and much colder.

The most noticeable feature of the week was the extremely violent wind in the early morning of the 15th; but it was not so great here as in other parts of the country.—G. J. SYMONS.

COVENT GARDEN MARKET.—OCTOBER 17.

A VERY dull market the last few days, large quantities of Apples remaining on hand, reduced prices failing to effect a clearance. Kent Cobs a good sale, quotations fully maintained.

From observations taken near London during forty-three years, the average day temperature of the week is 54.8°; and its night temperature 37.3°.

PREPARING FOR WINTER IN THE KITCHEN GARDEN.

ANY owners of gardens, especially those of the amateur class, think that when the kitchen-garden quarters are cleared of their summer crops it is not necessary to do anything to the ground until it is wanted again for next year's crop. This is certainly the easiest way of gardening, but it is not by any means the best either for the ground or what has to be put in it, nor those that expect anything out of it. Turning over

the soil and leaving it as rough on the surface as possible is the first thing we do at this time of the year as the ground is cleared of any kind of vegetable. The ground is very firm on the surface after most crops have been removed; if left like this during the winter neither frost nor wind, both excellent fertilisers, would ever penetrate beyond the surface. Heavy land especially is greatly benefited by exposure to the atmosphere in winter, and the lightest of soils is sweetened. We do not dig-in any manure now, as much of it would be decayed by cropping-time. This is put in when the ground is again dug, immediately before the crop is put in.

Not a weed should be allowed to grow amongst any winter vegetables, especially amongst low-growing crops, such as Spinach, Turnips, Endive, Lettuce, &c., as the more these are sheltered, drawn-up, or protected in any way now, they will be the more tender in the colder months to come. Plants are also much more liable to damp and decay when closely surrounded by weeds than when everything is clear about them. One good cleaning now will keep them right for the winter. Weeds look as untidy in the kitchen garden in winter as summer. Those on the ground now will grow if left all winter, but if they are cleared away now no more will spring up for some months.

We lifted all our Carrots the other day; it is not wise to leave them in the ground after the end of this month. Clean the soil roughly off them as they are dug up, lay them out thinly in an open shed for a few days to dry, and then store them in a cool shed or cellar, putting layer after layer amongst dry river sand. Beetroot is stored in the same manner, but when it is lifted the leaves are not cut off close to the crown like the Carrots, but they are twisted off with the hand a few inches from the crown to prevent bleeding. When cut close they lose much of their juice. Parsnips we leave in the ground all winter, only lifting a few when frost threatens. Salsify is treated in the same way. Onions have been under cover for some time; most of them are strung and hung up in a shed. This is the best way of keeping them.

Young Cauliflower plants for early spring planting are dibbed closely together in a two-light frame. The lights are never put on unless in a continuance of rain or frost. Sometimes we never cover them with glass at all, but put a hurdle over the frame in hard weather and cover it over with dry bracken. This reminds me that this is

one of the very best covering materials. Wherever it can be had, no time should be lost in cutting and laying in a large rick of it. There are some hundreds of acres in the deer park attached to the Castle here covered with bracken, so we have no difficulty in getting what we want. It is an excellent protector and not so littery as straw. We not only use it for frames, but spread it lightly over Lettuce, Endive, and such-like things when frost occurs, and find it answer capitally.

Small Lettuce, to stand the winter and plant-out for the early spring supply, should never be protected excepting when it is actually necessary. Ours remain in the bed in a south border in which they were sown until they are finally planted. Many err in covering up these kind of things now when there is no frost but only a little cold at night; this blanches them and makes them tender, when they should be hardened to withstand the frost.

Care should be taken not to over-earth Celery; always leave the centre above the soil, or the centre heart may decay in the damp days in winter. In the time of snow or frost bracken is an effectual covering for Celery.

Begin blanching Endive some weeks before it is wanted. In dry weather it is a good plan to tie the whole of the leaves up in a bundle at the top. In wet weather the centre often rots when tied up. Previous to the middle of October we tie them up; after that time we lay thin deal strips over each row, and blanch it in this way.

As soon as Asparagus stems begin to wither they should all be cut off, the bed cleared of weeds, and then covered over to the depth of 2 or 3 inches with rich dung. We shall begin lifting the roots for forcing the first week in November, to have a good batch of it in by Christmas.

Peas and Dwarf Kidney Beans are nearly over; stakes from these, if not rotten, may be stored away for mixing amongst new ones next year. Our outside Dwarf Beans are succeeded by those in deep frames, and seed will be sown in pots about the end of this month to come in about Christmas when the kitchen delicacies are scarce. Rhubarb should be covered over like Asparagus.

All kinds of Winter Greens should be gone over every other week and all decayed leaves removed. By breaking and turning a few leaves over the heads of Broccoli when they are beginning to show through the small centre leaves, they keep for several weeks longer than when left exposed to the weather. Cabbages to come in about May next year may yet be planted. Dutch-hoe frequently amongst those planted some weeks ago, and as soon as they are tall enough draw a little soil to their stems.

Globe Artichokes should be cut down to about 1 foot from the ground, then pack some bracken or long litter close round the stems without covering the top. Jerusalem Artichokes we leave in the ground and lift as required.

Old plantations of Strawberries should be trenched down 2 feet at once. Leave the soil rough on the surface as in digging. I do not see many recommending it, but we always fork-in a quantity of manure between our Strawberry rows about this time. Strawberries which

have been planted for two or three years require assisting with manure, and I find it does them most good when forked-in about 2 inches below the surface.

Fruit trees we never plant until the leaves are fallen, but preparation may be made for planting them now by getting some good loam together, and chop it up ready for putting to the roots as soon as planting begins.—A KITCHEN GARDENER.

TEA ROSES.

I AM of opinion, from the little experience I have had with Tea Roses, that a great future is in store for them and us. I believe they have never yet been grown to anything like perfection. They are often worked on the wrong stock, generally placed in a wrong position, and always coddled too much.

They will not last long on the Manetti unless they are planted sufficiently deep to form roots of their own above the union. As standards they are generally miserable objects; on cultivated seedling or cutting-Briars as dwarfs they do fairly well under favourable conditions; but where the soil is suitable I prefer them, as I do Perpetuals, on their own roots. Indeed Tea Roses on their own roots have more advantages than Perpetuals have, because the very life of a Tea Rose is its suckers. When it ceases to throw-up strong shoots from the base it is nearly all over with it.

Cuttings are very easy to strike. July and August are perhaps the best months to insert them, as they only require a hand-glass and a little shade, but half-ripened shoots will strike freely at any time in a cold close frame. I prefer getting them rooted, potted-off, and partially hardened before winter, giving them just sufficient shelter to prevent them losing their leaves during the first winter, and potting them on in January, never allowing them to become anything like pot-bound or stunted, for if such a thing once happens they are afterwards only fit to be thrown away.

If intended for planting-out, 8-inch pots will do for them, and are none too large, as they ought not to be planted-out before the end of May, and then if all goes on well they will produce some good flowers in the autumn. If intended to be grown in pots the above size is not large enough to carry them through the summer, and they ought, if want of indoor space prevents it in the spring, to be placed in pots 10 or 12 inches in diameter early in summer. I have a batch of plants, little more than twelve months old now, which have produced a few fine blooms through the summer, and promise to make large plants in the spring. They have lately been shifted into 14-inch pots, and will be kept in a house where the frost is merely excluded. They will not cease growing under these conditions, and will throw-up a few odd flowers through the winter and bloom profusely in April and May, or earlier if assisted with a very little warmth. Forcing spoils them.

The soil used and recommended is fresh turfy loam, mostly in pieces from the size of a hen's egg to that of half a brick, a good sprinkling of half-inch boiled bones, and a little charcoal.

For Tea Roses out of doors I believe the best possible position, in the southern and western counties at least, is a well-drained north border adjoining a hothouse or other building, to the walls of which the shoots can be tacked and be free from much frost and also much sun, while they enjoy full exposure to the air. Amongst several plants in such a position a temporary roof was erected over one last winter, and that very plant, selected because it was a good one, was the first to have mildew and has done the worst ever since.—WM. TAYLOR.

TRANSPLANTING FRUIT TREES.

In the description of the destruction of property during the late hurricane mention is made of the uprooting of hundreds of Apple trees in Herefordshire; but unless these trees were old I should think that this accident may turn out beneficial rather than otherwise. It is proverbially an ill wind that blows nobody good. Has not Nature, in this case of uprooting Apple trees, herself done what cultivators have been so often enjoined to do in vain? Will not trees when replanted be more likely to yield fruit in future years? I have myself this year gathered delicious Apples from a tree which was transplanted two years ago; but my experience has been not so much with Apple trees as with Peaches and Nectarines in the orchard house, and it has taught me that an uplifting of trees planted in the ground in alternate years is a good preventive against the growth of gross wood. Trees will grow thus if not discreetly checked. It is one of the arts of orchard-

house culture to restrain over-luxuriance, for those gross shoots which look so well to an inexperienced eye produce only barren shade. The Romans knew this full well. Your classical readers will no doubt remember the lines in which a youthful poet—after describing the causes of such fertility, that Bacchus wondered at his own Grapes and Minerva at her own Olives, and the weight of the fruit was so great as to threaten to break the branch unless a prop were placed underneath it for its support—proceeds:—

"But since the Plane tree, whose umbrageous leaves
Afford a barren shade, most praise receives,
We too the bearing trees, if such am I,
Broader and more luxuriant leaves supply."

Now mark the result:—

"And now no crop is gathered year by year."

My advice is, any time after the leaves have fallen, lift all those trees which have been making gross shoots. I urge this, not because it is a novel expedient, for it has long been recommended by the best authorities, but because I have found it by my own personal experience to answer, and now is the time to be thinking about it. Take that opportunity to give your trees a good winter dressing, so as to keep them free from scale, aphides, and red spider. Gishurst is a good compound for that purpose.

I ventured in the earlier part of the season to give your readers some account of the quantity of fruit in my orchard house this year. Out of the 1600 fruits I suppose as many as 500 fell off in the stoning, but the remainder proved excellent in quality; no sleepy Peaches, no woolly ones, but all luscious. One Peach in particular (not one of those turnips that you sometimes see among the clingstones in October, but soft and melting) measured 11½ inches in circumference. While so many lost their hopes of a crop in the spring I attribute the preservation of mine to the good effect of lamp stoves in keeping out the May frosts. I find in my cordon border along a back wall 12 feet high an alternation of trees in 20-inch pots with those in the ground a satisfactory arrangement in the case of single cordons.—H. W. HODSON, *Ashwell Rectory*.

WINTERING GERANIUMS.

WHENEVER I see information given on wintering these plants I note that it is not of an encouraging kind to "small people" like myself, and yet those are the very people who are chiefly interested. A light place would, according to our instructors, appear to be indispensable, such as a greenhouse. No doubt a greenhouse is a great advantage to a garden, and is the best place for Geraniums; but I have wintered hundreds of plants without their having been in a greenhouse, and they have proved very useful. I have a greenhouse it is true, and this I fill with Geraniums—young plants which are struck in August. These are wintered in boxes, and in March they are "turved" (not potted) and placed in turf pits. These make fine plants, which commence flowering early and are planted in the more prominent positions in the garden. But several hundreds of plants are required in addition to those for planting in borders and beds in different parts of the garden, and these are provided on a plan which may be a rough one, but which is none the less useful, for the plants secured by it make a fine late summer and autumn display.

The plants are simply taken up in October and are divested of all the fibrous roots. The tops are also cut off, leaving not more than half an inch of the main shoots. The wood there is quite brown and hard, and is not prone to decay; at any rate, decay is prevented by dressing the wounds with dry fresh lime at the time the plants are cut down. These stumps—for stumps they are—are closely packed in boxes of moderately moist soil, which is placed firmly round the roots. By making the soil firm sufficient moisture is retained to keep the stumps fresh without watering them during the winter. If the soil is loose it speedily becomes dry, and when water is applied in winter decay succeeds.

The boxes are placed in an old building which is nearly dark and nearly frost-proof, and all that is required to preserve the Geraniums is to cover them with perfectly dry hay during severe weather. They are examined occasionally, and if there is any evidence of mould a prompt application of dry lime checks it at once.

Eventually buds are formed on the stumps, and shoots succeed—white if in the dark, green if under the influence of light. The great source of danger consists in the eyes pushing too soon and before the boxes can safely be removed to a light

position, such as a turf pit or cold frame. The best means of averting this danger is deferring the cutting-down and boxing to as late a period as possible. If the plants are cut down and placed in the boxes during the first week in October fresh growth will commence in November if the weather is mild, and failure is then likely to result; but if the work is not done until the last week in the month, then the eyes remain dormant until January, which is a great advantage, for before the shoots become drawn the boxes can be placed in a light position.

They are removed to pits and frames as early in the spring as possible. Some are potted, some inserted in square turves, and some replanted thinly in boxes in light fresh soil. They then make fresh roots quickly and grow as freely as weather will permit. The shoots are thinned out; this is important, and fine plants are produced by the end of May. When the boxes of plants are brought from their winter quarters they are placed under glass for a time, at least as many of them as can be so accommodated, and the others are protected as best they can be. Some of these die, but many live and flourish.

I learned this plan of preserving Geraniums in a nobleman's garden where thousands of plants were thus wintered and managed annually, and I have seen it successfully practised by a cobbler who has no glass except the windows of his shop and dwelling, and his garden is far brighter than those of his neighbours.

In cutting employ a very sharp knife, and cut the branches off where they are quite hard and close to the main stem. Trim the roots somewhat in the same proportion, removing the soft fibres, and with a little attention the unsightly stumps will in a few months become attractive plants.—A GROOM AND GARDENER.

THE POTATO DISEASE.

ANYONE using gas lime as recommended by your correspondent "W. G." (page 287), believing it will prevent the Potato disease, will, I fear, be disappointed with the result. We have used it in the following manner without success.

The end of last autumn we had a plot intended for Potatoes dressed with gas lime, using, as near as we can judge, 1 cwt. to a pole of ground. The lime was left exposed to the weather during the winter. In spring the plot had a heavy dressing of old decayed vegetable soil. The soil had been prepared in winter by being turned and well mixed with a good dusting of gas lime. In March this was dug in, and Potatoes planted at the time of digging. I have never seen Potatoes so badly diseased as they were this season from that plot treated as I have described. We did not use lime thinking it would prevent disease, but to check wireworm, which it did to a great extent.—THOMAS COOMBER.

FLOWER GARDEN NOTES.—No. 2.

AFTER the early part of August we had rain almost daily, July being a wet month, telling disastrously upon Roses, yet we had some fair flowers, some, indeed, fine. The best were Alfred Colomb, François Michelin, La France, Baroness Rothschild, Marquise de Castellane, Sénateur Vaisse, Charles Lefebvre, Madame Lacharme, Madame Victor Verdier, Dupuy-Jamain, Claude Levet, Thomas Mills, John Hopper, Prince Camille de Rohan, Boule de Neige, Etienne Levet, Comtesse d'Oxford, Exposition de Brie, Queen Victoria, François Courtin, Jean Dalmais, Edward Morren, Louis Van Houtte, Maréchal Vailant, Charles Rouillard, Baronne Louise Uxkull, Annie Laxton, Felicien David, Miller Hayes, Thomas Methven, Marquise de Chambon, Madame Chirard, Madame Boll, Madame Clert, La Ville de St. Denis, Duchesse de Caylus, Dr. Andry, Capitaine Christy, Baronne de Prailly, Bessie Johnson, May Turner, Arthur Oger, La Souveraine, Antoine Moutin, Sir Garnet Wolseley, Princess Antoinette Strozio, Mariette Biolay, Miss Hassard, and Olga Marix. Gloire de Dijon was, as usual, fine as to flowering, but the summer blooms were all "quartered," scarcely a flower passable, yet it fully redeemed its character in September, and is now (October) giving some good blooms, being the best of the few autumn bloomers we have this year, followed by Alfred Colomb, La France, Charles Lefebvre, Olga Marix, Sénateur Vaisse, Baroness Rothschild, Boule de Neige, Thomas Mills, François Michelin, François Courtin, John Hopper, and Madame Lacharme. The Bourbons have plenty of buds all "glued" up, or very imperfect flowers. They seldom do any good in autumn in this part (North Riding of

Yorkshire), it being usually too cold and wet. The best this year have been Reine Victoria, Baron Gonella, Sir Joseph Paxton, Armosa, Catherine Guillot, and Louis Margottin. None have stood the wet and cold better or so well as the old Blush or common China, which is really very pretty in the bud, and forms a fine bed; Cramoisie Superieure also forming a fine mass. The continual downpour was too much for the foliage, which was to a great extent mildewed; the parasites and the wet weather combined have stripped many plants of their leaves, they being as bare of foliage now as we usually find them here in December.

Gladioli of the Ramosus section did not flower until the early part of September, and are more irregular in flowering than has been the case previously. I do not consider the plants of the same kind not all flowering together any drawback, but rather advantageous, as the continuity of flowering is considerably prolonged, there being fully a month between the first to flower and last—indeed more, some not having flowered as yet (October 6th), being later than many kinds of Gandavensis. The spikes of Ramosus are much more useful for cutting than those of the more shapely Gandavensis vars., some of them, as Ne Plus Ultra, having a fine branching habit, which amounts to as many parts for cutting as there are branches, and a spike or branchlet with two or three expanded flowers is as useful for vases as a spike as many feet in length. I usually cut the spikes when the lowest flowers on the spike are fully expanded. The peeping flowers are an attraction, they opening as certainly in a cut state as upon the plant; in fact, the spikes last a long time, as we have only each time the vases are supplied to remove the faded flowers, cut off a corresponding length from the stem, and the spike is as good as the day it was first cut, and continues until every bud is blown. No flower surpasses the Gladiolus as a cut flower. The Gladioli season is opened early in June with Byzantinus, Communis albus, Communis roseus, Blandus, which has the advantage of being sweet; Cardinalis and its variety roseus, and Colvilli with its variety alba, certainly one of the finest for cutting. These are all hardy, succeeding in any well-drained soil, planted about 4 inches deep. They increase rapidly, forming fine clumps, which require to be taken up about every fourth year and divided. September or early October at the latest is the time for renewing the clumps. Fresh-planted bulbs are not nearly so effective the first season as subsequently; indeed, they annually increase in effect as the masses become established. They do well in peaty soils and sandy loams well drained.

The Ramosus hybrids are almost equally hardy, and ought not to be taken up annually, nor at all only for purposes of increase, and then planted again as soon as possible. I planted dry bulbs this year and have lost several from "yellows," being unable to account for the irregularity of flowering in no other way than that the roots had been taken up before they were matured. When left in the ground I do not remember to have seen a single plant collapse of "yellows." I shall leave the Ramosus vars. in the ground, and have some hankering after trying the Gandavensis vars. in the same way, as our soil appears to suit the bulbs well, being a vegetable one of a sandy character overlying a cool bottom. A neighbour leaves his bulbs in the ground, the soil being well drained; "All that is wanted," he says, "is a free open soil and situation sheltered from winds, mulch, and watering copiously during growth." All I can say is, my friend has some grand spikes and laughs at the mention of "yellows." Taking up, he insists, is only necessary in heavy wet soils and for trade purposes. "It only weakens the bulbs, late planting and early lifting ruining them." Be that as it may, over-stimulation may have something to do with it, and so it will ever be with plants cultivated upon the high-feeding system essential to secure the spike and flowers that can only satisfy exhibitors. There is one peculiarity of Ramosus vars. that is not often recognised—namely, they last longer in bloom than Gandavensis vars., the family giving matchless spikes for cutting from June to December, the cutting not impairing but adding to the vigour of the bulbs in a future season.

Phloxes, herbaceous, were kept from flowering by the rain and cold, and it is a flower that will stand as much wet weather as most; but the end of September setting in fine, and October promising to be a real Michaelmas summer, the plants recovered wonderfully and produced some immense heads of flowers, finer indeed than at any earlier date. It is surprising how the roots increase, what great clumps they become; a mass a yard across and as much or more high, with a hundred stems, each sup-

porting a bouquet of flowers, make a grand display in herbaceous or shrubby borders. All they require is a free soil liberally manured and an open situation. No plants surpass them for affording a quantity of effective beautiful flowers with so little trouble and expense. The only trouble is to keep the clumps within bounds and manure in mulch form liberally. A collection, or rather selection, should be in every garden, alike for effect and cutting from.

Pyrethrums were fine in June, but the late-summer or autumn flowers have not made their appearance. There is no plant that slugs are so fond of as this; to keep them under sprinklings of soot should be given, and in winter some sharp ashes placed around the crowns are a good application, as the pests when having their own way make quick work of the plants. Dusting with quicklime destroys all the slugs it falls upon.

Pinks did well, but Carnations, especially Cloves, were much damaged by the wet, the flowers rotting; those having the fullest flowers—i.e., most petals—were glued up, those rather thin opening more freely. The end of September and early October (the promise being yet good) being finer than any previously. Their great beauty and fragrance are always appreciated; indeed no flower, excepting the Rose, is held in higher esteem.

Stocks had their central spikes good, when the wet completely converted them into a rotten mass; the flowers being individually large only helped the ruin. The plants struggled on bravely, and are now finer than I have ever seen any in October. The per-centage of single to double-flowering plants was greater than usual. I consider fully two-thirds of the plants had single flowers, a characteristic of Stocks in general this season.

Aschers did not so much as show colour until the close of September, it being remarkable what an influence sun exerts upon plants, and surprising what a few days' bright weather effects. The season has certainly been too cold for them.

Marigolds have given very indifferent flowers—very coarse and badly marked. An improvement has been induced by the weather. September shows should this year have been held in October. African Marigolds stood the weather much better than the French.

Dahlias, notwithstanding the wet, have flowered well and grown strongly. The Dahlia is one of the very best of flowers for a display in late summer, the dwarf varieties making grand beds, and the bouquet sorts are truly superb for decorative purposes.

Verbenas have been wretched, the great trussed kinds being the worst, and the pips of none can long withstand rain. The erect growers, as Lord Raglan, have been the best; those of prostrate habit have done nothing but grow.

Scabious, than which there are not many sweeter useful flowers for cutting, grew luxuriantly, and are now rewarding with a profusion of perfect half balls in various shades of colour. I wonder prizes are not offered at late summer shows for cut blooms. They are handsomer and in greater variety of colour than Marigolds.

Phlox Drummondii made strong growths. These are really very useful and effective plants with a great diversity of colour and marking. Prizes for a dozen heads of flowers—distinct varieties—should form part of the schedule of all late summer shows. The flowers withstood the wet well, and will continue flowering until frost.

Sweet Peas, which combine delicate sweetness with beauty of flower, were practically useless until late September, when they flowered profusely. I would even offer prizes for these as cut flowers—any and every plant in fact that affords variety, being of a useful decorative character—with a view to encourage a taste for those plants within the reach of everyone. Double Jacobæa, double Indian Pinks, and many others may be named as very effective and of the easiest culture, that are well worth the attention of the framers of schedules, whose chief aim appears to be to honour what are chiefly luxuries of the wealthy, instead of fostering a taste for hardy plants at the command of everyone possessed of garden grounds. Great sums as prizes for material that is more to be measured by the means at command than upon the skill required in cultivation lead but to one result—the bringing-out of "lions" paraded from one show to another, the same plants doing the grower or purchaser justice for years. It frustrates the aims of the promoters—the advancement of horticulture, and its dissemination among the masses.

Hollyhocks may, as regards flowering, be put down a failure. Not a flower expanded until October; but as it is said to be

"better late than never," so it may be with this stately flower. Taken altogether there are more flowers this year in October than at any earlier period. The weather appears to have suited very few plants; notable exceptions are the Primula family, Daisies, and the genus Viola. Pansies are blooming as freely now as in early summer. I had some seed of the French Impératrice Eugénie, and such a mottled, dotted, striped variety of flower I have not before seen, nor in so great variety of colour. No one can but be interested by such great diversity of flowers, some of them being really marvels of tint and shades of colour, a few having really well-formed flowers. They beat the Belgians hollow.

There is a great promise of Violets (Victoria Regina and Neapolitan), and we have been gathering them since the middle of September. Hardy spring flowers are remarkably vigorous, giving promise of a great bloom in due season.—A.

NEW HYACINTH GLASS.

MESSES. STEVENS & WILLIAMS of Brierley Hill Glass

Fig. 62.

Works, Staffordshire, have recently registered a new Hyacinth glass with support, of which we append an engraving. When not required for Hyacinths the glass can be used for cut flowers. The rod does not at all interfere with the bulb, as it can be applied by means of a spring outside the glass, thus obviating the employment of any hooks or screws. The supports for the leaves and flowers are made of brass bands, the flat sides of which alone touch the plant. By this means accidental bruising or cutting is prevented. These supports are also so arranged that they are able to slide up and down. The top support is capable of admitting the spike of the flower without any difficulty, and it is at the same time of sufficient strength and firmness to uphold the largest Hyacinth.

IMPROVEMENT OF LIGHT SOILS.

It is just possible that the statement of "CIRENCESTER AMATEUR" on page 290 in last week's number may deter some readers of the Journal, whose garden soil is too light to produce good Strawberries, from trying the great improvement they may effect at a slight cost by surface-dressing their soil with a moderate quantity of clay in preference to burying it, otherwise I would waste neither your space nor my time in noticing his assertion that "it would be necessary to go at least 5 feet deep," &c. Deep cultivation is all very well, but has anyone ever prepared a bed for Strawberries 5 feet deep? We may next be called upon to prepare for Radishes yards long, and Carrots running down to the greensand. But after all, in such a matter no amount of argument is worth one carefully conducted experiment.

Let anyone make a bed on light soil according to "CIRENCESTER AMATEUR's" instructions of any novelty he recommends, and prepare a similar bed for British Queen by spreading 3 or 4 inches of clay on the surface, leaving it exposed for the winter, and then mixing it in with the top spit just before planting, which should be done with runners from a nursery bed early in the spring. The next season, immediately after the fruit is gathered, the plants are to be dug up and replaced with the earliest runners that can be obtained, or plants from a reserve bed the same as the first season, and so on for a season or two, till it is evident whether the permanent bed of novelties, said to be suited to light soils, or the British Queens are the best.

Three or four inches of clay will practically convert the top spit into loam. After some years I should trench and clay again. In most districts a little judgment and forethought will provide all the clay that may be required at a trifling cost; but if every load has to be carted from a distance I should adopt a plan, which I believe is carried out at Loxford Hall gardens by Mr. Douglas, of placing a shovelful of strong loam round the roots of each plant as it is put out. Few of your readers can have worse soil to contend with or produce better results.—ESSEX.

FILBERT CULTURE IN KENT.

THE Filbert (*Corylus avellana*)—a corruption of "full beard," as it was originally styled, to distinguish it from smaller nuts—so highly appreciated at dessert, is cultivated extensively in the neighbourhood of Maidstone. It is not grown to any extent beyond a circuit of seven or eight miles round that town, though there are a few plantations at Ightham, about thirteen miles north-west of it, and in the West Kent fruit-growing district. It does well upon the soils of the ragstone, but thrives exceedingly upon the Atherfield clay, locally called the "coomb," which has been described as follows by a practical farmer:—"There is a very narrow belt of land running along the escarpment of the ragstone, which, though of a very heavy and adhesive texture, is astonishingly productive in Hops, fruit, and grain." The situation best suited is a southern slope, sheltered from rough winds, which are apt to snap off the delicate shoots in the early spring and bruise the blossoms. Filbert trees are always grown on cultivated land, planted under standard Apple, Pear, and Plum trees. Fruit bushes are generally planted as well. Filbert trees are set about 18 feet apart, giving 257 trees to the acre: they are invariably propagated by suckers obtained from old trees, and put in nurseries until they are two or three years old, being carefully pruned and trained to the required form.

The first operation in an established Filbert plat is to open a small trench round each tree, to get the suckers or "spawns" from off the roots and lower part of the stems. Rags, shoddy, fur-waste, sprats, "sheep-trotters," hop-bines, are used for manure. Digging the land is done with the spud peculiar to Kent, before Christmas if possible; before the trees are pruned, that the bloom, which appears very early, may not be rubbed off. Pruning or cutting Filbert trees is a most elaborate process. Each branch is examined by the tree-cutter, who leaves the finest young wood that he sees, or ought to see at a glance if he knows his business, to be bloom-bearing, and cuts away all wood of coarser, older growth, comparatively unfruitful. The "bloom," or cluster of pistilline flowers, is remarkably pretty, like a small scarlet star upon the extremities of the shoots. It is fertilised by the "catkins," as the staminate flowers are called, growing on the same branches, some of which are left by the judicious cutter. After the pruning the trees look mere skeletons. A stranger who had seen Filbert trees thus naked and forlorn in the winter would be surprised to see them in September with a wonderful wealth of leaves, branches, and nuts upon them. A typical tree has a stem of about 2 feet in height, from which the branches are trained to spread out laterally, and to form a centre of a saucer-like shoot, with a diameter of 7 or 8 feet, and a height of about 6 feet. After pruning, nothing is done until July, when most growers have the long suckers taken from the middle of the trees, and the leading shoots are broken off to relieve them from the burden of supporting unproductive wood. Mr. Webb states that he saw some Filbert trees near Maidstone which had grown 40 lbs. of nuts on each tree. A crop of a ton, or even more, is occasionally grown; but the average yield may be set at about 8 cwts. per acre.

Filberts are frequently sold on the trees, as the growers have Hops to attend to, and do not want the trouble of picking and selling them at the busiest time of the year. They are for the most part sent to Covent Garden in sieves which hold about 28 lbs. of green and 40 lbs. of ripe or harvested nuts. It is customary to send a portion of the crops to London when the bunches are quite green, and the kernel not by any means developed. There is a certain demand for these, as they look well on the table, though at this time they have but a mere *soupeon* of the true Filbert flavour. When Filberts sell well at this stage some growers send their whole crop up, as the weight of green nuts is nearly double that they would have if duly harvested.

Prices of Filberts range from 5d. to 1s. per lb., according

to the supply. They are not much influenced by the competition of foreign nuts, none of which have the flavour or the appearance of the genuine Kentish Filberts, although the quantity of nuts of all kinds imported is very large. The value of the imports of this duty-free fruit, which chiefly comes from Belgium, France, and Brazil, amounted to £584,325 in 1875, as against £408,291 in 1871.

The Kent Cobnut, or Lambert's Filbert, is superseding the old-fashioned Filbert in a degree, and is generally preferred for new plantations; it is a much larger nut than the Filbert, with a thicker shell, and is a more hardy and more abundant bearer. As these trees do not thrive so well under standards as Filberts, they are now generally planted by themselves, with bushes under them, or with Plums, Damsons, or half-standard Apple trees. They are treated in the same way, requiring, perhaps, to be cut a little harder than Filbert trees. A casual observer would not notice the difference between Cob and Filbert trees, but their leaves are different; the whole growth of the former is more vigorous, and its "bloom," or pistilline cluster, is darker than the Filbert bloom. As a rule, Cobnuts make rather higher prices than the Filberts.—(*Royal Agricultural Society's Journal*.)

CHRYSANTHEMUMS FOR EXHIBITION.

As the shows of this fine autumn flower are approaching, a few hints on the management of exhibition blooms may not be inappropriate. Last year the best kinds opened very early, and such as Beverley, Aurea Multiflora, Prince Alfred, Queen of England, Empress of India, and several good varieties were over before showing commenced. This year the plants are a little later, and good stands ought to be forthcoming. I have frequently noticed flowers staged with very bad centres, some flat and reflexed, others with too much centre through not taking them in hand sooner. If the plants be looked over carefully, or rather the flowers, every day, taking each flower about fourteen days before it will be up in the centre, and take the eye carefully away with a pair of tweezers, then by tying the flower down facing the floor or stage will make a great difference in the appearance of it when wanted for the stand, especially such sorts as Queen of England, White Globe, Empress of India, Prince Alfred, and all the long-petaled varieties. It will also retard the flowers if getting too forward. Some will say flowers well grown should not have an eye, but it is almost impossible to grow them without. Also, when the flower comes very full without an eye the middle of the flower often spoils a stand through the petals being small and often of another tint of colour; therefore, all this should be removed as I said above, and in the same manner as the eye. It will be found that the space will soon be covered by the other petals. Such kinds as Aurea Multiflora, George Glenny, and Mrs. G. Rundle seldom want dressing at all unless exposed to too much sun, which is very injurious when the flowers are erect; but if suspended will not injure them so much. This will be found a far better practice than to place the blooms in dark sheds and cupboards, as I have seen done frequently, which destroys the colour of the flower before half open. I have seen Golden Eagle, Rev. J. Dix, Princess of Wales, and other varieties exhibited with not an atom of their true colour left through being exposed too much to the sun.

The very best way to bloom the Chrysanthemum, to obtain superior flowers and good colour, is to place the plants in a vinery or Peach house, if span-roofed so much the better, placing the pots at the sides of the house and tying the plants to the wires, allowing the flowers to hang down. They will enable the cultivator to look into his flowers and keep them free from vermin much better than when the plants are crowded together in a large bed. I have written more for the instruction of the young beginner than for the experienced exhibitor.—J. P.

TEA ROSE NARCISSE.

I COULD never discern why this little gem of a Rose has not found more favour with the Rose-growing public. If I were asked to name one Rose for general usefulness I should not hesitate for a moment to say Narcisse. I am fully aware of the "old Gloire's" claim. I do not forget many others; their worth is fully acknowledged when I say, Give me Narcisse for any of them.

"But it is a Tea," you will say, "it is too tender." Not a bit of it; it is as hardy as old Gloire, and such a little beauty,

when once you have it nothing will induce you to give it up. Its lovely soft, delicate, creamy-coloured buds render it a perfect button-hole flower. I have never found lady or gentleman that would not always have it before any Rose that I could give them, and most strange it seems, it was new to most if not all of them.

A gentleman said to me one day early in the summer, "Ah! how much I should like a house to grow such exquisite Rose buds as you always have." This very bud was plucked from an old standard some eight or ten years old, and had been replanted last autumn. This same old standard *Narcisse* has produced more Roses than any half-dozen Rose trees in the place. This says not a little for its hardiness. Its beautiful, clean, bright foliage stands out most conspicuous amongst all others in this most trying season of blights of all sorts. Never before did I see mildew and rust so bad as this season. Plant *Narcisse* in a sheltered situation, worked on the Briar, prune but little, feed it well, and you will have Roses early and late from it; in fact, it is difficult to go for a bud and be disappointed. I daresay I have had not less than four dozen buds off this same old tree this summer. No Rose is equal to it for bouquets. It is simply lovely so used; it is fine for ladies' hair as well as for placing in rooms, &c. May I not ask, Why is this good Rose not often met with?—J. TAYLOR, *Hardwicke Grange*.

GRAPES CRACKING.

At page 272 Mr. Harris seems to be of opinion that it is not within the compass of man to solve the mystery of Grapes cracking, and Mr. Inglis at page 285 is of opinion that atmospheric humidity is the cause. My theory to some extent clashes with both, still I hope to be able to bring forward facts which will substantiate my theory.

I believe there are varieties which are more liable to crack under certain conditions than others. Much, I believe, depends on the constitution of the variety.

Many will remember the humid state of the atmosphere last autumn, and how badly Grapes kept. I had a house with a few Black Hamburgs and White Frontignan still hanging in it. The Hamburgs were totally destroyed with crack and mould, but not one berry of the Frontignan was affected; and I believe that its firm Muscat flesh and dwarf habit just saved it, while the soft sappy berries of the Hamburgs had a greater affinity for the damp which brought their ruin. This result I believe rests entirely in the difference between the two Vines.

Cracking arises generally from two causes brought about by the same thing—the want of moisture at the root and in the house. After a spell of dry weather we generally have a spell of wet weather, which not only saturates the border but creates much moisture in the house. If the Vines have not been sufficiently supplied with water during the drought they will now gorge themselves at both roots and foliage. The skins of the berries having become hard and brittle from want of moisture will not expand suddenly, hence they crack. This applies more particularly to those varieties having a voracious nature, such as Madresfield Court, White Tokay, Lady Downe's, &c. Last season I had a clear proof of this. In a vinery I had a few Muscat Hamburg and Lady Downe's; the former is characteristic of being very moderate in its demands for feeding—so moderate, it is often not able to perfect more than half a crop; and although the border was deluged with rain, and the atmosphere at the point of saturation, not a single berry of this Grape either moulded or cracked, while, on the other hand, nearly all the Lady Downe's did. I believe the reason they cracked so badly was, they were kept too dry outside and in.

I have Madresfield Court grafted on Black Hamburg in an early house, where it gets lots of moisture, and I have little or no cracked berries. I know it was sparingly supplied with sap, as it never coloured right till after some of the Hamburgs were cut from the Vine; then it coloured, as if by magic, jet black.—B. G., *Co. Down*.

OUR BORDER FLOWERS—PHLOXWORTS.

THIS is one of the choicest of all the numerous families of our hardy border flowers. I believe we are indebted to the North American continent for the choicest of these our spring beauties. They are deserving of every attention that can be afforded them, and when well grown they cannot fail to give satisfaction. They attract attention by their compact habit,

bristle-like leaves and stems, and their carpet of lovely flowers in the sunny days of spring. I have proved their merits under a variety of circumstances. For indoor decoration in pots in early spring they are invaluable; and on sunny slopes, on the rockwork, or in the border, they are highly attractive. They are worthy of a place also on the exhibition table.

They are a very accommodating race of plants, and are of easy culture. They succeed well in any ordinary garden soil, but they are impatient of much moisture. For lines and edgings in the spring garden and for beds and patches they scarcely have an equal. They are quite at home on the limestone, and I think in such situations their flowers are particularly deep in colour. They are readily increased by division after flowering, or by cuttings during summer and autumn in well-drained pots in sandy soil, in a cold pit, or under hand-lights in a shady situation. They must be kept free from damp. I have never been able to increase them by seed—i.e., those dwarf spring-flowering varieties. I am not now alluding to the splendid kinds that belong to the florist-flower department, of which there are so many magnificent varieties in cultivation, but to our little spring gems.

One of their greatest recommendations is that they are cheap and within the reach of all who have any pretensions to spring gardening or border decoration. A bed of *Phlox verna*, known also by the names of *P. reptans* and *P. stolonifera*, rooting from the runner-joints like the Strawberry, is one of the most beautiful. *Phlox subulata*, with its white variety known as *P. Nelsoni*, make a charming pair. *Phlox frondosa* when in good trim gives us sheets of lovely pink flowers, lasting a long time in bloom; it is one of the very best rock plants we possess. *P. canadensis* is a useful plant; it is one of the tallest of the dwarf kinds, and deserves more attention than it is at present receiving. *P. procumbens*, *P. ovata*, and *P. suaveolens* are all worthy of extensive cultivation. *P. setacea* is one of the dwarfest growers of the family; there is a white variety of this species, but it is of delicate constitution, and is seldom met with in cultivation.—VERTAS.

RAISING TREES FROM LEAVES.

THE first who made this art known was Agostino Mandirola, Doctor of Theology, an Italian minorite of the Franciscan order. In a small work upon gardening, printed for the first time at Vicenza, in duodecimo, in the year 1652, and which was reprinted afterwards in various places, he gave an account of his having produced trees from the leaves of the Cedar and Lemon, but he does not relate this circumstance as if he considered it to be a great discovery; on the contrary, he appears rather to think it a matter of very little importance. His book was soon translated into German, and his account copied by other writers, such as Böcker and Hohberg, who were at that time much read. A gardener of Augsburg, as we are told by Agricola, was the first who imitated this experiment, and proved the possibility of it to others. He is said to have tried it with good success in the garden of Count de Wratislau, Ambassador at Ratisbon from the Elector of Bohemia. But never was this experiment so often and so successfully repeated as in the garden of Baron de Munchausen at Swobblor. A young tree was obtained there from a leaf of the *Limona rivo*, which produced fruit the second year. It was sent to Mr. Volkamer at Nuremberg, who caused a drawing to be made from it, which was afterwards engraved, in order that it might be published in the third volume of his "Hesperides;" but as the author died shortly afterwards it was not printed. The exact drawing as it was then executed at Nuremberg, and an account of the whole process employed in the experiment at Swobblor, were published by the Baron de Munchausen himself from authentic papers in his grandfather's own handwriting. No one, however, attracted so much attention to this circumstance as the well-known George Andrew Agricola, physician at Ratisbon, who, with that confidence and prolixity which were peculiar to him, ventured to assert that trees could be propagated in the speediest manner by planting the leaves, after being steeped in a liquor he had invented; and for the truth of the assertion he referred to his own experience. Among the naturalists of that period none took more trouble to examine the possibility of this effect than Thunning, who endeavoured to prove that not only leaves with eyes left in them could in well-moistened earth throw out roots which would produce a stem, but that leaves also without eyes would grow up to be trees. Baron Munchausen, on the other hand, assures us that, according to the many experiments made in

his garden, one can only expect young plants from the leaves of those trees which do not bring forth buds; that experiments made with the leaves of the Lemon tree had alone succeeded, but never those made with the leaves of the Orange or Lime tree; and that Agricola and Thunberg had erroneously imagined that the leaves themselves shot up into trees, their midrib becoming the stem, and the collateral ribs or veins the branches. It is probable that the well-known multiplication of the Indian Fig gave the first idea of this experiment; for every joint of that plant stuck into the earth, and properly nurtured, throws out roots and grows. As these joints were commonly considered to be leaves, people tried whether other leaves would not grow in the same manner. Luckily those of the Lemon tree were chosen for this purpose, and what was expected took place. Thus from a false hypothesis have new truths been often derived; and thus was Kepler, by a false and even improbable opinion, led to an assertion, afterwards confirmed, that the periodical revolutions of the planets were in proportion to their distance from the sun. But the raising of trees from leaves was too rashly declared to be a method that might be generally employed, for it is certain that it now seldom succeeds.—W. R.—(*Journal of Forestry*.)

NOTES AND GLEANINGS.

THE importation of POTATOES this year is much larger than in 1876. In September of this year 184,459 cwt. were imported; and in the same month of last year, 176,348 cwt.

— AMONGST the many fine examples of Palms and Tree Ferns in the conservatory of Mr. B. S. Williams of Holloway is a noteworthy example of *TODEA AFRICANA*. The specimen has been recently imported. Its stem or trunk is about 5 feet high, is roughly triangular in form, and measures nearly 9 feet in circumference. It has seventeen crowns from whence healthy fronds issue, these measuring from 3 to 5 feet in length. The plant is a very striking feature in the conservatory, and is much admired by visitors on account of its singular form and venerable appearance.

— WE have received the REPORT ON THE BRISBANE BOTANIC GARDEN, and are pleased to see that it testifies to the successful management of its Curator, Mr. Walter Hill. The glass structures, the drainage, and other details have been improved; 104,000 cuttings, 22,000 roots and bulbs, 21,326 plants, and of seeds 1046 packets and 46 lbs. have been distributed among public and private establishments.

— AN American bouquetist observes that a very pretty and tasty BOUQUET for summer time may be made of scarlet Geranium, Begonia Weltoniensis, or some other pink flower, Catalonian Jasmine, Browallia elata (blue), and a few Fern leaves. The first two varieties should be used for base flowers, the next two for projecting, and the Ferns for edging. In making the bouquet alternate the scarlet Geranium and Begonia. It is immaterial that these flowers be packed together, as the Browallia and Catalonian Jasmine will make the bouquet light and graceful. These two should be cut from the plants with long stems, as the buds are almost as pretty as the flowers. They should be projected about 3 inches above the other blossoms. There should be about twice as much Jasmine as Browallia, as a very little blue will make a much greater effect than the same quantity of white. Edge the bouquet with some light and graceful Fern leaves, and a gratifying result will follow. A round-top nosegay is preferable to any other style when made as above described, because the projecting flowers show with greater effect.

— IN reply to "F.," who has sent us a M.S. on plants written by SIR JOHN HILL, it is sufficient to state that he was a physician, but wrote upon any subject the booksellers paid him for. Amongst his publications were poems which occasioned many satires, among the most clever of which were these:—

"The worst that we wish thee
For all thy vile crimes
Is to take thy own physic
And read thy own rhymes."

The rejoinder to which was—

"No! Let the order be reversed,
Or he'll not rue his crimes;
For if he takes his physic first
He'll never read his rhymes."

Sir John Hill died in 1775.

— THE American *Cultivator* truly observes that POTATO tops are valuable either as a green manure for ploughing under

or as an addition to the compost heap. The stem and leaves of the Potato contain a good per-centage of the most valuable organic and inorganic elements of plants. According to Fromberg 100 lbs. of the leaves in their natural state contain from 0.82 to 0.92 lbs. of nitrogen, or 100 lbs. of dry leaves contain 5.12 to 5.76 lbs. of nitrogen. By every ton of Potato tops ploughed under we add to the land about 50 lbs. of inorganic salts, and a quantity of organic matter containing 20 lbs. of nitrogen, or about 23 lbs. of ammonia. The best Ichaboe or inferior African guano yielded but 9 to 10 per cent. of ammonia, hence one ton of Potato tops may in this respect be compared to 250 lbs. of cheap guano.

— GLUE FOR DAMP ATMOSPHERES.—A glue, fast in damp atmosphere, for fastening labels on preserve bottles may be made by macerating five parts of good glue in from eighteen to twenty parts of water for a day, and then adding to the liquid nine parts of sugar candy and three parts of gum arabic. The mixture can be brushed upon paper while lukewarm; it keeps well, does not stick together, and when moistened adheres firmly to bottles. For labels to be used in places subject to damp it is well to prepare a paste of good flour and glue, to which linseed oil, varnish, and turpentine have been added, in the proportion of half an ounce to the pound. Labels prepared in the latter way do not fall off in damp places.

— WRITING to the "*Journal of Forestry*" on the importance of TRENCHING THE GROUND FOR TREES, "*THE SQUIRE'S OLD GARDENER*" narrates the following experience:—About twelve years ago a gentleman having determined to make a considerable number of clumps or plantations on various parts of the estate, it fell to my lot to see to the work being done in a proper manner. I advised my employer to have the whole of the ground trenched 2 feet deep, which he at once agreed to have done. The soil varied from good loam to stiff clay, and in some parts a shallow sandy soil resting on rock, the stone cropping up in places at less than a foot deep. Before the work of trenching was completed my employer was advised by a person in whom he had great confidence that I was putting him to a great deal of unnecessary expense, and that if holes were dug 2 feet wide and 1 foot deep it would answer the purpose, and act as well as the trenching I was giving it, and so the trenching was stopped, and holes were dug in the remainder of the ground, and the young trees were planted. They consisted of Spruce and Scotch Fir, Birch, Elm, and Poplar, as well as various kinds of dwarf shrubs, all being alike strong and healthy plants. The planting was done in November, and every tree lived for the first two years, all appearing to flourish alike; but then we had a very dry hot summer, when a change came quickly over the scene. Where the soil was trenched the trees seemed to revel in the heat, and sent their roots deep down into the good soil prepared for them, while the plantations on the ground not trenched appeared scorched and stunted and all growth stopped, many of the trees dying, and those that remained alive never recovered their former vigour.

IN THE NORTH.—No. 3.

NEWTON STEWART.

IN my report of the Galloway Rose Show I have alluded to the zeal for horticulture which is manifested in this far south-west corner of Scotland, and have spoken of one of the places in the neighbourhood where a good example of gardening is set, but I think a somewhat more detailed account of it and another of the country houses in the neighbourhood may not be uninteresting to the readers of the *Journal*. They do not pretend to be show places nor even to be great gardens, but they are none the less a proof of how widely extended is the love of gardening amongst us.

PENNINGHAME CASTLE.

This beautiful spot, the seat of Stopford Blair, Esq., is situated about four miles from the town of Newton Stewart amidst the most lovely wild scenery. Seeing it as we did on a brilliant day in July when it was looking at its best, we can well understand how much its owner must rejoice in it when escaping from the bustle of a London season. Doubtless it tells (like most country places, and especially those in mountainous districts) a very different tale when wintry weather prevails. The Castle stands on an elevated plateau overlooking the river Cree, and the view from the flower garden in front of the house commanding that of the windings of the river is very beautiful. The beds in the garden were well filled with

the usual bedding plants, although, like every other place that I have seen this year, they were three weeks behindhand. The houses are situated in the kitchen garden, which is walled in; and although small in extent, showed in all the departments the results of care and attention, which after all go a longer way in the ordering of most things, gardens included, than very great cleverness. Having with me two of our very best rosarians—Mr. George Paul of Cheshunt and Mr. Cant of Colchester—we had a talk over the curious way in which the Roses are affected, and to which I made allusion last year, the leaves all curling and blistering-up as if they would never do any good, but getting the better of it as the season advanced. We discussed the various causes that might effect it—the soil, want of manure, so that the plants were probably deficient in vigour, situation, &c.; but I think we all came to the conclusion that it was due to atmospheric changes. The cold north-

easterly winds, which, severe as they are everywhere, would when they occur perhaps be more injurious in so generally mild a climate; and yet there must be something also in the special situation, for I saw nothing of it among the other Rose-growers in the neighbourhood. My two companions were as much struck as I had been last year with the beautiful *Tropeolum speciosum*, which was full of bloom, and would, we were assured, so continue until cut down by frost. No matter what was the situation or position it thrived well: springing out of a gravel walk, under Apple trees, or on a warm border, it seemed alike to flourish, and displaying in all directions its brilliantly coloured scarlet flowers; but I imagine in our more southern climate that it will do best with a north aspect.

The season has been here, as everywhere, against the production of out-of-door fruits; but the various small fruits were abundant and all parts of the vegetable garden in good order

Fig. 63.—PENNINGHAME CASTLE.

and the cleanliness and order of everything reflected much credit on the painstaking gardener Mr. Duthie.

CAIRNSMORE,

The then residence of Mr. Stewart, whose death I saw announced the other day in the *Times*, is an old-fashioned place, but its laird was an accomplished botanist, and in his garden had managed to get together a fine collection of the old herbaceous plants that our fathers used to delight in. In an evil hour he engaged a gardener who looked upon all these things as weeds and nothing to be compared with the brilliant reds and yellows of the modern style of bedding-out, and so, as the old laird was not able to get about as he used to do, he had it somewhat in his own way. However, there is a dawn of better things, and the collection is gradually coming back to its former condition. The garden is large, the soil good, and both afford by their large wide borders great facilities for the growth of herbaceous plants. Amongst other things there was a bed of *Primula japonica*, which I was told when in bloom was the most brilliant thing imaginable. Fine clumps of the old *Dictamnus Fraxinella* were most beautiful. Lovely little bushes of *Menziesia* and the white variety of it, grand pieces of *Spiræa*, were here to be seen in full bloom; then as we walked round fine masses of *Delphinium*, *Phloxes*, and other plants of a similar character everywhere met the eye. It may be prejudice, but I cannot but think there is more pleasure

in going round such an old-fashioned garden as this and meeting everywhere some fresh beauty, than going to some spick-and-span place where there are fresh masses of colour and trimly arranged beds over which the scissors has so constantly to pass; for while in a kept garden there must of necessity be some violence done to natural growth, yet this excessive trimness is a violation of all the canons of good taste. *Rhododendrons*, of which there is an excellent collection of fine named varieties, flourish here, as do all shrubs, most vigorously.

I wrote last year of the difficulties under which my friend Mr. Mackenzie follows out his gardening tastes; let me only add this year that he is still manfully fighting against the rude elements, and has by his example done much to encourage the taste for horticulture in and around Newton Stewart. By-the-by, last year I said the town seemed to have no higher industry than sawing wood and curing bacon. Let me correct myself, for I was this year shown some of the most artistic and novel inventions in the way of toilet ware I have ever seen. The inventor is Mr. Vernon, and the great novelty of it consists in the letting-in of indiarubber to the bases of the jugs, basins, &c., used; so that they are perfectly noiseless, and the possibility of breakage reduced to a minimum. They are most artistic in design, and I have no doubt by-and-by when they come to be more fully known will meet with general adoption, and both Mr. Vernon and his fellow townsmen may be well

congratulated on the marked proof of inventive genius and talent they display.

In my notes of the Rose Show I have stated what I cannot but reiterate, that nowhere amongst my wanderings do I meet with more thorough kindheartedness and hospitality than amongst the lovers of gardening in this somewhat remote Scottish town; and in this I shall, I am sure, be joined by Messrs. George Paul and Cant, who were my companions on this occasion.—D., *Deal*.

DEATH OF MR. THOMAS RIVERS.

It is with feelings of great regret that we have this week to announce the death of Mr. Rivers of Sawbridgeworth, which took place on the evening of the 17th inst., about half-past eight o'clock, in the 80th year of his age.

now among the oldest existing in this country, were commenced some time between the years 1720 and 1730 by John Rivers, who was a native of Berkshire, and so they have been in the possession of the same family for a century and a half at least. The extent of the grounds at that time and for some years after was, like the beginning of most great enterprises, limited, and might be regarded as an easy-going common-run sort of country nursery, the produce of which consisted of anything, no matter what, by which an honest penny was to be earned. Fruit trees and forest trees for the neighbouring gentry, Cabbage plants for those who had gardens, and market-garden produce for those who had none; flowers, fruit, and nosegays were alike in readiness for all comers, and, that the tastes of each might be further gratified, one of the staple commodities was a glass of good currant wine. To such an extent did this last branch of the business become, that in 1761 we find his

Fig. 64.—MR. THOMAS RIVERS.

For a long time past the sad event was looked forward to by his family and those who were most intimate with them with feelings of sadness and of hope—of sadness at the prospect of parting, and of hope that a life of so much energy and usefulness would not be prolonged in a state of suffering; for during the last four or five years Mr. Rivers has been a confirmed invalid, and totally laid aside from work of any kind. Though his mental faculties were sound to the last he has long suffered from disuse of the lower limbs, and the disease from which he suffered appears to have been a sort of creeping paralysis, which gradually extended upwards till it reached the vital parts, and thus ended peacefully a life of marvellous energy, an intellect of no ordinary compass, and the work of one who has added perhaps as much as anyone to the pleasures and enjoyments of his fellow creatures.

Mr. Rivers was born at Sawbridgeworth on the 27th of December, 1798. He came of a long line of ancestors who had followed the same calling in the same place for nearly a century at the time of his birth. The nurseries, which are

son and successor, Thomas Rivers, actually built, for the preservation and maturation of his domestic vintage, an immense vaulted cellar, 30 feet long by 10 feet wide—a fact which he recorded, for the information of subsequent generations, on a square stone bearing the initials of his name and the date of the year when the event took place. The cellar is still in existence, and is now applied by the present proprietor for the purpose of a fruit room, and a very excellent one it is. The house at that time was known by the sign of "The Fox;"* and the swinging board, which for several years battled with many a summer's breeze and winter's blast, is still in possession of the family, having been converted into an article of household furniture; but the pictorial delineation of "The

* Many of our readers may not be aware that it was customary in those days, and for many years afterwards, for nurserymen and seedsmen to designate their establishment by such signs. The more common were "The Acorn," "The Rose," &c. George Ricketts, at Hogsden (Hoxton), adopted "The Hand;" Edward Fuller, in the Strand, "The Three Crowns and Naked Boy;" and Francis Weston's, in the Strand, was known by "The Flower de luce."

Fox," and the announcement of the host, "I shall be at home myself every Tuesday, Thursday, and Saturday," have unfortunately been obliterated. This Thomas Rivers was the late Mr. Rivers's grandfather's uncle, and was so successful as to die the proprietor of the place he and his father had previously occupied as tenants.

The nursery grew in extent and importance with every change of successor, and on the retirement of his father in 1827, Mr. Rivers took the whole responsibility of the establishment on his own shoulders, so that from that time what was comparatively of moderate extent gradually increased till it became what it now is, one of the largest in this country. In those days the plants cultivated were of a miscellaneous character, and such as were to be found in a well-appointed country establishment; but Mr. Rivers was always quick to perceive the rising of a popular attraction, and the first speciality to which he directed his attention was the extensive cultivation of the Rose. Formerly standard Roses were all imported from France, and Mr. Rivers set himself to produce at home what had hitherto been a lucrative article of commerce with the Paris and Rouen nurserymen. His attention was first directed to a specimen of the Apple-bearing Rose (*Rosa villosa*), which had been planted by some of his predecessors, and which had by treatment and age acquired the habit and magnitude of a little tree. This induced Mr. Rivers to train up plants of this species as standards; but it was found to be too tedious a process, and his attention was then turned to the ready-made standards of the Dog Rose which he found in the woods and hedges of his native county, on which to bud the choice varieties. In 1833 Mr. Rivers published his Catalogue of Roses, of which Loudon said, "This we consider to be the most useful catalogue of Roses in the English language." This was an imperial folio sheet for sending as a single letter by post. "The Rose Amateurs' Guide" first appeared in 1837, and in the space of forty years it passed through no less than eleven editions. This was the first really practical work on the Rose which had appeared in the English language, and it soon attained a reputation which established it and its author as the leading authorities on the subject. Mr. Rivers was also a raiser of Roses from seed, and there are many who still remember his George IV.

Although fruit trees had always been among the leading articles of the Sawbridgeworth as of other nurseries, about the year 1840 Mr. Rivers began to turn his attention more in that direction, and to give special attention to their culture, and so in that year he published the first edition of the Catalogue which in subsequent years has become so familiar to fruit-growers. In this year also appeared the first edition of the "Miniature Fruit Garden," which was the outcome of articles he had communicated to "London's Gardeners' Magazine" on root-pruning. Although root-pruning had been practised for centuries before, and the late Mr. Beattie of Scone Palace had not long previously advocated the practice, it needed an energetic mind like Mr. Rivers' to give it an impetus and to force it on the attention of the public. This he did, and did successfully, through the "Miniature Fruit Garden," which from 1840 to 1877 passed through eighteen editions, and has been the means of revolutionising the whole system of fruit gardening in this country. The first ideas he obtained of this system of fruit gardening were during a continental tour through France and Belgium, where he found small trees skillfully managed by being kept within small compass taking the place of the wide-spreading overshadowing standards and dwarfs that were so common in our own limited gardens. This mode of fruit culture has now taken root in the country, and where one or two trees formerly occupied a large space of ground a great number of small trees easily protected are now grown, affording a good supply of fruit and in greater variety.

About the year 1848-49 Mr. Rivers first conceived the orchard house. At that time the writer of this, on one of his visits to Sawbridgeworth, was conducted by Mr. Rivers to a part of the grounds where there were small square spaces enclosed with Beech hedges. These are frequently met with in nurseries as places for sheltering the more tender and delicate plants from storms and cutting winds, and it was one of these spaces that Mr. Rivers had covered with a glazed shade, the walls being nothing more than the Beech hedges. Within the space a turf bank was thrown up by way of a stage, and the path was slightly sunk to afford head-room. In this structure Peaches, Nectarines, and Apricots were growing in pots and laden with fruit. No ventilation was required, for the air percolated through the Beech hedges, and the only heat was that

derived from the sun and the shelter of the glazed roof. The success that attended this essay induced Mr. Rivers to attempt a more substantial structure, which resulted in the glazed roof being supplemented with boarded sides, and ventilation being admitted by openings at the front and back. This was found to be an improvement on the original erection, and in 1850 Mr. Rivers published the first edition of the "Orchard House." It was a pamphlet of very modest pretensions, and was written with the laudable object of its proceeds being applied to the repairing fund of the old parish church of Sawbridgeworth. The publication was very successful, and the amount obtained for the repairs was £189, which entirely cleared-off the debt which had been incurred. The first edition was in the form of a pamphlet the ordinary size of his nursery catalogues, and it passed through several editions in this shape; but this with his other works was ultimately issued in the duodecimo size in which they now appear. In the preface to the first edition the author anticipates the pleasure he was providing for those who love the pursuit of gardening. He says, "The method of culture given in the following pages has been to me a pleasant relaxation from the cares of an extensive business, and I feel convinced that it may be made equally agreeable to a numerous class of busy men who make their gardens a source of untiring quiet enjoyment."

The hold which the introduction of the orchard house took upon the gardening public was firm and rapid. The little work in 1859 had passed through five editions, and in the preface to the fifth we find these words:—"Orchard houses are now familiar things; hundreds are now rising up all over the face of the country; no garden structures have ever so rapidly advanced in popularity. That they deserve to be popular I am more than ever convinced, and I cannot help feeling grateful that, through the exercise of my humble literary ability so much good, because so much intellectual pleasure, has been derived from this new mode of cultivating fruit trees." The popularity of this work rapidly increased, so that in 1877 it had passed through fifteen editions.

But besides those works that were published separately Mr. Rivers contributed voluminously to all the current periodicals. His first appearance publicly was in "London's Gardeners' Magazine" in 1827, when, under the signature of "MALUS," he sent an article on "An Orchard in Miniature; or the Culture of Apple Trees as Dwarf Standards after the manner of Gooseberry Bushes." This, however, was not the precursor of the "Miniature Fruit Garden," the principle of which rests on root-pruning, and in this that operation is never mentioned. It seemed to consist in selecting the dwarf-growing varieties of Apples, such as the Nonpareil, for the purpose of grafting them on Paradise and Crab stocks. In the subsequent volumes of the Magazine his name as T. Rivers, jun., frequently occurs as a constant contributor. Mr. Rivers possessed a ready pen, and he was ever ready to communicate to others the knowledge which he had himself acquired, and of this the readers of this Journal can fully testify. For nearly thirty years he made the *Journal of Horticulture* one of the chief channels through which he diffused his extensive knowledge, and scattered the seeds of instruction far and wide to appreciating readers in these kingdoms and their colonies.

In 1870 a movement was set on foot to commemorate the services rendered by Mr. Rivers to the cause of horticulture. This took the form of a memorial portrait, to which a large number of his admirers subscribed, and the amount being much more than was needed for the portrait, the balance was given over to the Gardeners' Royal Benevolent Institution. An admirable portrait was secured, and it was handed over by Dr. Robert Hogg, who initiated the matter, to the Trustees of the Lindley Library, and it is now suspended in the hall of the Royal Horticultural Society along with those of Sir Joseph Banks, Professor Lindley, Mr. James Dickson, Mr. James Veitch, Rev. Joshua Dix, Mr. John Standish, and Rev. M. J. Berkeley.

During the last few years the Sawbridgeworth Nurseries have been under the direction of Mr. T. Francis Rivers, and they will still be continued under his management. That he may be long spared to continue and still further develop the resources of this great industry is, we are sure, the hope of all who hold in honour the family name.

GOLDEN QUEEN GRAPE.

I AM not sure that I can answer all the questions of "A GRAPE-GROWER" which appeared in your last number, but at least I think I can throw a little light on what to him seems

darkness. He seems to think that the prizes offered should have been awarded to the Grapes shown, no matter in what condition they were, because Golden Queen is a new and untried Grape. Surely "A GRAPE-GROWER" must be aware that this "new Grape" obtained its certificate in 1873, having then been proved for three seasons at Chilwell; that since that date it has been shown, I believe, three or four times before the Royal Horticultural Society's Committee; that it was also shown at Carlisle, Derby, and the Alexandra Palace, where there were not prizes specially offered for its appearance—for aught I know it may have been shown elsewhere, but these three cases I have heard of; that this "new Grape" has been in the hands of the public for the last two years, and is now offered in almost every Vine-grower's catalogue.

"A GRAPE-GROWER" must, I think, admit that the Judges of the Crystal Palace Show had some little experience and data to go upon when they pronounced the three bunches exhibited at the Palace unworthy of the prizes offered, even if Golden Queen has not quite the known excellence of Black Hamburgh. That the Judges were entitled to withhold the prizes I maintain, inasmuch as, having written to the Secretary of the Show to allow us to offer the prizes at the Palace, we placed the matter in his hands, and of course subject to the rules of the Show, and advertised that the prizes would be awarded by the Crystal Palace Judges.

I fear I have begun in the middle of "A GRAPE-GROWER's" questions, and must now note some of his earlier points. I hope I have shown by what I have written that we are not what your correspondent calls the holders of a new Vine, but that, on the contrary, Golden Queen is a Vine which has been sent out two years, and I hope I may say with an established reputation. Had it been otherwise we had been simple indeed, with a score or two of good bunches at home, to trust entirely to chance to see it well shown at the Palace; at any rate, its being shown well or badly will not make or mar its prospects.

As to your correspondent's last remark, of everybody's geese being swans or something to that effect, I can only say my late father sent out Golden Queen, and I think I may say with safety that his character has been long enough before the public to need no vindication from my pen.—ALFRED H. PEARSON, *Chilwell, Notts.*

THE OLD MARKET GARDENS AND NURSERIES OF LONDON.—No. 18.

RESUMING the subject of the suburb of Hammersmith I remark that, being somewhat farther off than Kensington and Brompton, and therefore rather beyond the influence of the movement westward which has so revolutionised the suburban districts in the vicinity of the Thames since 1830, it had, as much as Fulham, quite the aspect until recently of a place that had made up its mind not to be swallowed by the all-devouring metropolis. Now, perhaps, Fulham has retained more of its rurality, and the cause is obvious. At present Fulham has escaped the noisy railway lines which, ramifying across Hammersmith, have opened up new roads and called into existence piles of new buildings constructed on what we may term the "Hodge-razor principle" for the most part—that is, built to sell or mortgage, but with slight regard for the health and comfort of the occupants. And it may be esteemed a little curious, as Hammersmith was the early head quarters of the manufacture of London bricks, that much of the supply went to be used elsewhere; and up to twenty years ago Hammersmith with its park-surrounded mansions, its garden grounds, and open fields where cattle grazed placidly, might have deemed itself the rival of the northern Hampstead or the southern Norwood, though the rapid changes in Kensington should, so to speak, have made Hammersmith shake on her foundations. Possibly the disappearance of the Cedar, to which many a visitor was attracted as he passed through the suburb, may have been esteemed a bad omen. There is a place called "The Cedars" in the Hammersmith Road, and near these houses are two trees of this kind by no means despicable, but they will not compare with the original Cedar, the memory of which has almost vanished. This was reputed to be the finest produced in Britain; at its perfection the branches extended at least 80 feet from the trunk, which was 16 feet in circumference, and the height 59 feet. It bowed to the axe on September 1, 1836, yielding, it is said, 17,520 lbs. of that valuable wood. There are many fine old trees about Hammersmith still, chiefly Elms, Limes, and Poplars; the Oak, however, is as scarce as in most London suburbs, though

Oak woods once flourished in this part of Middlesex, as witness the not far distant "Acton," which is presumed to have been originally "Oak-town." And as yet the axe and the spade have left untouched Ravenscourt Park, the special delight of Hammersmith folk, who can no longer boast that they observe the old custom of tolling the curfew bell, though this was the last of the suburban parishes to drop a usage which was originated as a protection against fire. During the summer season in bygone times, after the curfew, there would start forth from the market gardens here quite a procession of men and women carrying loads on their heads intent on reaching Covent Garden about the day-dawn. This expensive and fatiguing plan of conveyance has been superseded, of course; nor are there now, as formerly, many girls engaged at Hammersmith who have come from their homes in Shropshire and Wales for a few months' employment, to return in September. Irish labourers are predominant, I think, amongst those at present engaged in the market gardens, judging from the specimens of dialect that greet the ear, nor is their urbanity at all remarkable.

The public-house signs in a neighbourhood are frequently significant; and at Hammersmith we have near the Vineyard Nursery the sign of the "Hand and Flower," and at Brook Green, once in the centre of market gardens, there is the sign of "The Jolly Gardeners." Possibly also the "Rose and Crown" may be reckoned with these, as it might have been suggested by some loyal gardener. Other signs, such as the "Plough and Harrow," the "Barley Mow," and the "Cock and Magpie" belong to the time when there were farmers who grew Wheat and bred cattle and poultry in Hammersmith. How much of significance there is in names that we often miss! For instance, "Bradmore," which is attached to one locality in Hammersmith, does not, to ninety-nine persons in a hundred, convey any thought; yet there is reason to suppose it represents "broad mere," pointing back to the time when a broad mere or lake-like pond connected with the Thames was situate here. Much of the land in Hammersmith must have been under water in some seasons before the drainage was improved—perfected it cannot be said to be; but as beneath the surface soil there is generally sand or gravel, except in a few places where loam prevails, it has always had the credit with gardeners of being one of the best districts near London, particularly for the culture of fruit.

Mention has been made of the establishment of the Messrs. Lee, which is, as I understand, likely soon to be a thing of the past in Hammersmith, for a sale has already taken place at the time-honoured "Vineyard Nursery," and the business of the firm will be carried on at their grounds farther out in the suburbs. Hence houses will cover the spot sooner or later. There may be, it is true, a "Vineyard Terrace" or a "Lee Crescent," I hope there will. Farther on in the main road, and before the Broadway is approached, there is another nursery of some standing occupied by Mr. Elmes, concerning which there is nothing special to record; like its neighbour, it is probably in peril from the builders. On the southern side of the road, and extending towards the Thames, much land is under cultivation by Mr. T. Steel, whose name is a familiar one amongst gardeners at the west of London, and who will, I trust, steel his heart against the tempting baits speculators may offer. This is not the only district where market gardens are owned by that firm. In Hammersmith, however, where every effort seems to be made to get the most from the land, the beauty of the scene is interfered with in order to increase profit. Hence much of the orchard ground has been cleared, a succession of vegetables being found more advantageous than the production of fruit, especially as the securing it from depredators is troublesome when the population is numerous. From the yet remaining orchards in the vicinity not many Cherries and Walnuts now go to the market, though Apples and Plums may. Few Pear trees were planted by the early gardeners, on the supposition that these did not flourish here.

The nursery of Messrs. Colley & Hill had a frontage (a narrow one, I presume) in King Street, and the grounds extended towards the Mall and overlooked the Thames. Vainly would the visitor now seek for any traces of a nursery which in its day sent many choice plants to public and private displays of flowers. According to Faulkner the establishment at the beginning of Her Majesty's reign was noted for its Auriculas, Dahlias, Verbenas, Fuchsias, Cyclamens, Tulips, Azaleas, and Roses, with other things unenumerated no doubt, for the worthy historian was evidently not very learned in plants, or

he would scarcely have added that the firm had a good collection of "hybrids." I have been unable to ascertain when the nursery was closed, but on some part of the land houses had begun to be built twenty years ago or more, and probably like some other nurseries its extent grew "small by degrees" through portions being taken off for scattered houses, till the remainder at last made way for streets. At Bradmore also, when Faulkner wrote, Mr. James Lee, jun., had about eight acres of nursery and garden ground, excelling in his Dahlias, Pansies, and Pelargoniums. The nursery of Mr. Wells at Brook Green, which is yet extant, was another of some repute; in 1838 there were attached to it seventeen acres. But the market gardeners were more numerous than the nurserymen, and amongst the principal of these forty years ago I find the following specified:—Mr. Clarke, holder of fifteen acres, Bradmore; Mr. Brookes, eight acres, Angel Lane; Mr. Deadman, fifteen acres, Red Cow Lane; Mr. Masters, ten acres, Hammersmith Road; Mr. Yeldham, ten acres, Fulham Road; Mr. Dobson, eighteen acres, Pallingwick Green. Between Starch and Brook Greens were Messrs. Browne, Hodges, and Martin, with ten, twenty, and thirty-six acres respectively.

Then there were amateur gardeners at Hammersmith deserving of a passing notice; but there were never here, as in some London suburbs, gardens belonging to the nobility, which served to help on the progress of horticulture. Occasionally, no doubt, Hammersmith nurserymen gained admission to the grounds of the adjacent Palace at Fulham, more famous for its flowers and shrubs in Georgian days than it is at present. The name of Louis Weltge is mentioned by writers on horticulture, he being a successful raiser of seedlings, which he distributed to a great extent gratuitously; he also devoted special attention to the *Auricula* and *Pelargonium*. Mr. Salter, in the reign of William IV., was presumed to have one of the finest collections of *Iris* in these islands at his garden near Shepherd's Bush. At this place was formerly the nursery belonging to Mr. Plimly, who was also a market gardener. In his forcing houses were to be seen, forty years ago, splendid specimens of the Queen and other good varieties of the Pine. From Lord Holland's establishment he received early examples of the famous *Dahlia purpurea*, which was raised in 1803 by his lordship's gardener from seed which that nobleman had brought with him from Spain. And there formerly lived at Hammersmith an eccentric old gentleman of the name of Keene, whose boast was of his garden in Vale Place and the Apricots and Peaches he gathered there. With a love of gardening he combined (oddly enough) a fancy for collecting black-letter books. Early in this century he was to be seen daily promenading the main road in a "brown suit of clothes surmounted by a brown, unpowdered, and highly polished wig, topped by a shovel hat," and flourishing in his hand a "hooked crabbed stick of stately dimensions." At Brook Green resided the celebrated Tulip grower Mr. Strong.—C.

NEW BOOK.

British Industries—Horticulture. By F. W. BURBIDGE. London: Edward Stanford, 55, Charing Cross.

UNDER the editorship of Mr. G. Phillips Bevan, F.G.S., a series of volumes on the industries of Britain have been prepared and published; and as horticulture was recognised as of sufficient importance to be represented in the series, Mr. Burbidge was commissioned to prepare the present volume. It is necessarily in a great measure a compilation, and the gardening press of this and other countries has been laid under contribution, and official records have been utilised and books of some private firms have been placed at the author's disposal, and the result is that horticulture for commercial purposes has been shown in a plainer manner than it was ever shown before. But the volume also contains much original matter—much that is both entertaining, instructive, and useful. There are chapters on fruit culture, vegetable culture, herbs, decorative plant culture, hybridising, and plant propagation, Covent Garden Market, fruit and vegetable preserving, gardening industry abroad, with allusions to some collateral industries, and last but not least in usefulness, a capital index. Such is the scope of the work, its nature will be best appreciated by a few extracts.

After stating that the capital employed in the leading metropolitan nurseries varies from £10,000 to £50,000, or even more, fruit cultivation is thus alluded to—

At the present time we are paying a sum of £6,000,000 annually for imported fruits alone, and yet news reaches us from the Continent that fruit culture is being rapidly extended in many

agricultural and pastoral districts, so satisfactory to the fruit growers are the prices now realised in our markets. France, Jersey, Holland, Spain, Portugal, and Turkey send us Grapes, Melons, and Figs; the great bulk of our imported Apples comes from France and America; Pears from France and the Channel Islands (from Jersey we annually receive £7 worth of Potatoes per acre for the entire acreage); and during the earlier part of the season, when Strawberries, Cherries, and Plums fetch good prices, our own growers have but a poor chance of competing with the continental cultivator, who, in addition to a sunny climate, cheap labour and transit charges, and in most cases freehold land, brings a vast amount of intelligent ability to bear on fruit culture as a profitable industry.

Now that the acreage of our Wheat and Potato crops is decreasing year by year, and the production of meat is yearly becoming more risky and less profitable, it is a matter of great moment that the importance of gardening as a food-producing industry should receive that attention which it so well deserves. That we should import Apples and other hardy fruits to this country at a yearly cost of nearly £2,000,000 is all the more remarkable when we consider how many thousands of acres of cultivated land are annually devoted to a far less remunerative industry—viz., timber-growing; when thousands of acres are left waste which might be made most profitable for fruit culture.

And now

That we have an ever-growing population of 30,000,000 people to feed, and according to the latest reports only about 40,000 acres of land specially devoted to vegetable gardens, the produce of which is regularly marketed, it need no longer surprise us that our trade in imported fruits and vegetables should be expanding year by year.

The orchard, or hard-fruit growing, area of Great Britain is given as being only 154,584 acres, or less than half the return for the American State of Illinois alone, where an area of 334,067 acres is occupied by orchards. Notwithstanding enormous imports, however, current prices are maintained, or rise rather than fall, so that it seems that the demand still exceeds the supply; nor is this demand altogether owing to increasing population, but rather to a growing taste for fruit and vegetables as articles of food among the more intelligent of our labouring population, who, it must be remembered, influence the sale of food commodities far more than the wealthier classes.

The author further states—

That fruit-growing may become a remunerative calling to any person of intelligence having a capital of from £100 to £1000 has been proved by the direct experiments of the Rev. William Lea, M.A., whose work entitled "Small Farms: How they can be made to answer by means of Fruit-growing" published at the *Journal of Horticulture* Office, is one of the most concise and valuable of any hitherto published on this branch of cultural industry.

The cost and value of growing different kinds of fruits are alluded to, and there are chapters on the cultivation of vegetables, detailing the practice of the London market gardeners.

Decorative plant culture is thus referred to—

This branch of gardening industry has been wonderfully developed during the last twenty years, and an immense amount of labour and capital has been devoted to the culture of ornamental plants in small pots suitable for sitting-room or window decoration, and also to the production of choice cut flowers of various kinds, from the choicest of tropical *Orchids* to the old-fashioned *Narcissus* and *Snowdrops* of our gardens.

Some years ago immense profits were made by plant-growers for markets, but competition in this branch of industry, as in those of vegetables and fruits, has done much to reduce these; at the present time, as a rule, but little more is made than a fair return for the capital and labour expended, and further competition in this field is not likely to be successful unless some fresh line of culture is adopted, or some striking novelty introduced into the market. In this branch of gardening the capital expended varies from £100 to as much as £2000 and even £5000 per acre.

Nearly all plant-growers for market have something of which they make a speciality. Mr. Beckwith of Tottenham sends to market yearly from 80,000 to 90,000 show and fancy *Pelargoniums*. The plants of the show and fancy kinds are struck in the spring, as early as cuttings can be obtained, and potted-on till they occupy 48-sized or 32-sized pots. They are subjected to gentle warmth, and abundance of air night and day when the weather will permit, and are copiously watered daily. The only kind of stimulant used in this great plant factory—for such it may be called—is soot water, which is applied of different strengths, according to the different stages in which the plants may be. This has the effect of dispelling worms from the soil, and imparting to the foliage a dark green healthy-looking colour.

Bulbs also occupy a very important position in this establishment, especially *Hyacinths* and *Tulips*. Of the former between 60,000 and 70,000 are forced yearly. Mr. Beckwith always contrives to send twenty dozen pots of *Hyacinths* to market the

day before Christmas. Tulip bulbs are placed in shallow boxes, in which they remain until flower-buds can be seen, when they are lifted and potted four or five in 48-sized or 32-sized pots, using good sandy loam for the purpose. The single Duc Van Thol is the principal variety grown. Another market grower, Mr. Reeves of Acton, imports and grows yearly as many as 160,000 Tulip bulbs. Mr. Smith, of Ealing Dean Nursery, makes a speciality of Cyclamen culture, and yearly sends 10,000 or more to Covent Garden and other markets. A very large house is devoted to the culture of Poinsettias, and a more brilliant sight than they present when in bloom can scarcely be imagined, thousands of large scarlet bracts being open at one time. These plants are grown in 48-sized pots, are about 12 or 15 inches high, and well clothed with large green foliage from top to bottom. In addition to these several thousand Solanums are grown, 10,000 Begonia Weltoniensis, 12,000 Cinerarias, and as many Fuchsias. Some growers devote themselves to Mignonne, Heliotrope, Hydrangeas, and Asters; while others make a speciality of white Arum Lilies (*Richardia athiopica*), Pelargoniums, Fuchsias, and perhaps Chinese Primulas or Cinerarias.

We can only at the present make one more extract from the chapter on collateral industries of gardening.

Directly and indirectly gardening industry is beneficial, as affording employment to thousands of persons, head gardeners and their assistants, labourers, artisans, and others, to say nothing of an immense number of extra hands, principally women and children, who are employed in gathering fruit and vegetables during the summer months. In our best market gardens we frequently find three to five hands per acre, and in nursery gardens of course the rate is much higher; indeed, gardening is, of all forms of land culture, that which affords the best market for labour, whether skilled or otherwise. Messrs. Crosse & Blackwell inform me they employ regularly over a thousand hands, and from three to four hundred extra labourers, chiefly women, during the fruit season, the annual amount of wages paid by this one firm alone being £50,000; this expense for labour is necessary to the due preparation and distribution of 1500 tons of fruit, and 10,000 hogsheads (500,000 gallons) of fruits and vegetables in a preserved state, either as pickles or sauces; and among the ingredients necessary for this wholesale conservation, we note 1200 tons of sugar, and about 500,000 gallons of vinegar, the latter being prepared by the firm at their own brewery. The consumption of corks, pepper, wire, paper, and wood for packing cases, is proportionately great, to say nothing of show-cards and the hundred little requisites of such an extensive business. We are not told the sum paid for the glass bottles and porcelain jars in which these preserved fruits and vegetables are packed previous to their distribution, but it must be something considerable.

Extensive as is the fruit-preserving and pickling industry in this country, our American neighbours are ahead of us in the matter, and, thanks to their rich and almost boundless tracts of alluvial lands, they are enabled to supply half the world with canned fruits and vegetables of excellent quality and at a cheap rate. It has been estimated that of Cucumbers alone 100,000 barrels are pickled annually in the United States; these, on the average, being worth £4 per barrel; if those put up in jars with vinegar and spices be included, it gives a total value of £400,000 for this one product alone, to say nothing of Tomatoes, green Corn, Cranberries, Bartlett Pears, Blackberries, Apples, and other fruits, and the thousands of tons of Apples, Pears, Plums, and vegetables now preserved by the Alden and other desiccating processes.

We commend this modest little volume to our readers, and believe that not many of them will rest satisfied without reading it through.

SINGULAR TREES.

THERE are many species of trees growing upon the earth's surface of a very peculiar nature and entirely unknown in this region of the world. For instance, the Brazilian Nut Tree, a native of the country whose name it bears, affords a delicious fruit and grows to an average height of 75 feet. The fruit resembles a Cocoa-nut, and is about a third larger. Each ball contains from twelve to twenty nuts, three-cornered in shape and nicely packed together. During the season of their falling it is dangerous to enter the forest without a shield, as the force of their descent is sufficient to knock down the strongest man. In Guinea they have the Cannon Ball Tree, growing to the height of 60 and 70 feet, bearing a flower remarkable for beauty and fragrance, being of a brilliant crimson; the fruit resembles large cannon balls. From the shell various kinds of domestic utensils are made, while the pulp affords two kinds of acids, sugar and gum, besides material for an excellent drink in sickness.

At Goa, near Bombay, they have what is known there as the

Sorrowful Tree, because it flourishes in the night only; at sunset no flowers are seen, but in half an hour after the tree is full of them. As soon as the sun shines on these blossoms they close up again. The flower has a sweet smell and blossoms all the year. On the side of Mount Etna there is a famous Chestnut tree, measuring nearly 200 feet in circumference just above the surface of the ground. Its enormous trunk is separated into five divisions, which gives it the appearance of several trees. In a circular space formed by these large branches a hut has been erected for those who collect the great yield of Chestnuts, which are four times the size of those growing upon our New England Chestnut trees. A similar fruit is produced in the south of France, and is sometimes to be seen for sale on the corners of the streets in our northern cities under the name of Italian Chestnuts. In the country where they are grown these Chestnuts form no inconsiderable source of sustenance, being extremely palatable and nutritious when roasted.

There is a most curious dwarf tree, unknown, we believe, except in the mountain region near Cape Horn, only about 3 inches in height, yet with regular branches spread out 4 or 5 feet along the ground. In Bombay there is what is called the Sack Tree, because from its trunk and branches may be stripped a natural sack which resembles felt in appearance, and which is in universal use among the inhabitants. The Ivory Nut Tree is very common in South America. It is a species of Palm, the nuts making choice buttons and small ivory articles, while the broad and substantial leaves form a covering for the huts of the natives. The Butter Tree is found on the banks of the Niger in Africa, and from it excellent butter is obtained. The tree is like our Massachusetts Oak, and the fruit somewhat resembles the Spanish Olive. The kernel of the fruit is boiled, and the butter thus obtained is whiter, firmer, and of a richer flavour than is that from a cow, besides which it will keep a year without salt. This brief mention by no means exhausts a subject to which we may again refer.—(*American Cultivator*.)

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

KITCHEN GARDEN.

THE weather is still fine, but too cold at night for Dwarf Kidney Beans, Scarlet Runners, or even Peas, to do any good. Indeed ours have been over for some time, and in no season have Peas ever done well with us in the autumn. Where Cauliflowers have formed heads these must be protected from the frost. Some persons merely break or bend one or two of the inner leaves over the heart, but a better way is to tie them together over it with a strip of matting. Some gardeners lift the plants where the heads are not yet formed and lay them in deeply in a sheltered place rather close together with the heads inclining to the north; the plants are then easily protected by having a few light mats laid over them in frosty nights, or some dry straw may be used for the same purpose. Endive should also be tied-up to blanch, but this must be done when the leaves are dry; so also should the Cauliflower leaves. The plants are easily injured by damp at this season, and they may be kept quite dry by having an 11-inch board placed ready to lay over them; it may be kept above the plants by having bricks laid on the ground to support it. Lettuce and Cauliflower plants may now be planted in frames to stand over the winter. We generally plant the Lettuce in the open ground, but the vicissitudes of our winter sometimes make sad havoc amongst them, and it is well to have a small reserve to fall back upon. We shall soon have the hand-lights filled with plants of Early London and Walcheren Cauliflower.

If the late Potatoes have not yet been lifted no time should be lost in doing so, as they can only take harm now that the haulm has been destroyed by frost. We have tried many plans to keep them, but the most convenient next to a frost-proof shed is to make a clamp or pit of them. This is done by digging out the ground to the depth of from 4 to 6 inches, and then carefully put in the Potatoes in the form of a cone or long ridge, according to the quantity to be put in; then thatch them with dry straw of any sort, and cover the straw over with about 6 inches of soil; this will protect the Potatoes from any amount of frost, and they may be taken for household use as they are required in fine weather.

As the weather is so fine and the ground dry, Carrots, Salsafy, Scorzonera, Beet, and other roots should be lifted and stored, as they keep well when lifted in such a dry state during a fine dry day. If the ground between growing crops is close and hard a good plan is to run the Dutch or draw hoe through the ground; even if there are no weeds the crops are much benefited by it.

VINERIES.

It is very desirable to pay particular attention to the fruit hanging in the late house. The leaves are now falling rapidly, and owing to the evaporation of moisture from them the berries are more liable to mould than they are at other times. All that can be done is to keep up an equable temperature in the house and to remove the leaves as soon as they fall, or to pick those off from the Vines as soon as they cease to be useful. The dense fogs have also set in generally at night, and sometimes continuing till mid-day. Last Thursday at 11 A.M. it was so dense that a person could not be distinguished at six yards. This is what tries us the most, especially if the fogs are continued for many days. We are now making arrangements to renew the border of one of the early vineries; the roots have penetrated beyond their bounds, and no doubt they have gone through the drainage into a bed of gravel underneath. We shall cut a trench through the border parallel with the front wall and about 6 feet from the Vines. All the roots on the further side of this will be cut off, and the whole of the old compost will be removed. After that has been removed the rubble at the bottom will be turned over, removing from it all the particles of loose earth; the rubble will then be levelled over the bottom and some turf be placed over it with the grass side down. The next thing is to work into the old border that remains, and level about 6 or 9 inches of this into the bottom before putting in the compost that has been already prepared. We do not use it any richer for this than it was used for the border when the Vines were planted. The component parts of a Vine border have been so often described that one would think it was known to everybody, had not a correspondent written last week to ask if the following would answer to make a border for Vines—viz., to twelve cartloads of turfy loam add six cartloads of stable manure, two loads of lime rubbish, and twenty bushels of crushed bones. It was fortunate that the correspondent wrote to the Editors for information, else a large expense would have been incurred to end in failure. One load of decayed manure is sufficient for six or nine cartloads of loam according to its quality, and 1 cwt. of crushed bones would be enough to add to it, with two bushels of charcoal. A cartload of lime rubbish might be added to six cartloads of heavy loam or nine cartloads of light loam.

PEACH HOUSES.

As in the case of vineries, preparations must now be made to begin forcing the earliest house by washing the woodwork, dressing the wood of the trees, and renovating the borders. Besides being subject to the attacks of red spider, thrips, mildew, and green fly, the wood is often attacked by brown scale. This pest does much injury when it is allowed to increase unchecked. Before painting the wood with the mixture the scale ought to be washed off with a sponge dipped in soapy water. The wood ought also to be tied into the place where it is permanently to remain, and then, if it is necessary to put any plants into the house, they may be arranged on a temporary stage in the most advantageous position. In the late house the leaves will nearly have all fallen except on such sorts as Salwey, Comet, Lord Palmerston, or other late sorts. A suitable ripening temperature should be kept up, and as soon as the fruit can be detached by hand it ought to be gathered and removed to the fruit room, where it will keep in good condition if required for ten days.

PLANT STOVE AND ORCHID HOUSES.

At present we are not doing much except to clean the plants, pots, and stages, glass, and woodwork, both outside and inside. Whatever plants are flowering should be attended to, and the flowers be preserved for as long a period as possible. Many of the same plants are in flower that we alluded to a few weeks ago, and they continue quite as long again now as they do in summer. Nearly all the summer-flowering plants are approaching the resting period of their existence, and should not be excited by too much heat combined with moisture at the roots. *Clerodendron Balfourianum* and *Bougainvillea glabra*—two of our most useful stove plants either for decorative purposes on the home stage or for exhibition—will stand over the winter in a warm greenhouse, but they must be very sparingly supplied with water; indeed, they will scarcely require any. These and plants of a similar character will pass through the winter in the stove. They will not start into growth if water is not supplied to them. Poinsettias are now forming their flower bracts. These plants must not be over-watered, and an over-moist atmosphere does not suit them. They require a temperature of about 60° at night. A little guano water, or manure water formed by steeping sheep or cow manure in water, adds greatly to the strength and brilliancy of the floral bracts. We have the old variety and the new sort introduced to England by the Messrs. Veitch of Chelsea two or three years ago, and it is interesting to notice the difference in growth between the two, and also that the new sort is later in forming its bracts. It was thought that this new variety would displace the old sort altogether. We do not think so. They are both required; the old variety to flower earliest, and the variety plenisima to prolong the display at least two months longer than heretofore. Keep the plants close to the glass and admit as much air as possible, still keeping up

the temperature to about 60° at night and 65° or 70° by day. We would again urge the utility of the winter-flowering *Calanthes*. Now that the bulbs can be purchased at a very cheap rate, and can be grown in an ordinary stove amongst other plants, every collection should contain them. We simply pot the bulbs when they start into growth in February or March—three small in a 5-inch pot, selecting the largest bulbs to be potted in 6-inch pots. Turfy loam with a little decayed stable manure added is the best potting material; they do better in this than in peat. *C. oculata rosea* and *lutea* are the earliest to flower, to be succeeded by *C. Turnerii* (pure white) and *C. Veitchii*, the beautiful hybrid we owe to the skill of Mr. Dominy. Of these there are many shades of colour, from pale rose to crimson. The noble *Odontoglossum grande* is very beautiful at this season, and is easily grown. We have it in the cool house with *Odontoglossums* from New Grenada, and in the Cattleya house with the Mexicans. The variety *O. grande leopardinum* has the labellum of the richest gold and crimson bars; the sepals and petals are also much darker. *O. bicornense* is easily grown, and its spikes tower erect above most others. *O. autumnalis* is throwing up vigorous spikes, but the flowers will not open for a month yet. Although many plants are in flower or showing, it is not well to excite them with too much heat or moisture. We keep the *Odontoglossum* house about 50°, a few degrees less or more according to the weather; the *Cattleya* house about 55°, and the East Indian Orchids 60° to 65°.—J. DOUGLAS.

TRADE CATALOGUE RECEIVED.

Charles Turner, Royal Nurseries, Slough.—*Catalogue of Roses, Fruit Trees, &c.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

BOOKS (B. E.).—"Greenhouses for the Many," price 6d., or "Garden Manual," 1s. 6d.

INSTRUCTION (Pimlico).—Write to Messrs. Veitch.

TURNTIPS (A Lady Reader).—They are stringy if they have produced stems for flowering. They are best kept by being buried in sand in a cellar.

FERN (A. McDonalld).—It is *Asplenium fontanum*.

LEAVES (L. H.).—We cannot name from leaves only. The Vine roots have probably descended into an unsuitable soil. Manure the surface over them. *Echeverias* may be wintered in a greenhouse.

TYING FRUIT TREES (E. W.).—Stockholm-tarred string is not injurious to the tree tied with it, but you must adopt means to prevent the bark being chafed.

TRELLIS (Sambo).—Train over it Ivy and *Crataegus Pyracantha*.

SALSAFY (A. S. H.).—Sow in March and April in an open situation in shallow drills 9 inches asunder, scatter the seeds thinly, and cover them half an inch deep. When the plants are 2 or 3 inches high thin to 10 inches asunder. During very dry weather water occasionally very plentifully, and if half an ounce of guano is added to each gallon of water it will be very beneficial. They will have large roots by September or October; and in November, when the leaves begin to decay, a quantity may be preserved in sand for use in time of severe frost, but those left in the ground will not be injured. In spring, when those remaining in the ground begin to vegetate, the shoots when a few inches high may be cut for use as Asparagus, being excellent when quite young and tender.

CELERY (W. J.).—Dig a trench and bury the sticks, leaving the green tops uncovered.

VINES MILDEWED (L. H. and G. F.).—They seem to have had a slight attack. You can do nothing now until the leaves fall, when you must prune the Vines; then wash the wood with soapy water, and paint it afterwards with a mixture of flowers of sulphur stirred in soapy water till it is of the consistency of thin paint, add to it a little tobacco liquor. No harm will be done to your Vines if the wood is well ripened. Vines are most subject to mildew when they are unhealthy. Probably the roots have gone down into unsuitable soil; if so it would be best to raise them as you propose and put in fresh soil. Vines are more subject to mildew in a greenhouse than they are in an ordinary vinery. The low temperature is the cause. When the parasite appears dust the leaves with flowers of sulphur. The gas stove would not cause mildew. Paint the Vine when dormant with the sulphur mixture.

LATE-KEEPING APPLES (A. B. C.).—Gooseberry, Wellington, Blenheim Orange. *Ranunculus* will not do well behind a north wall.

TREATMENT OF ORANGE TREES (Idem).—They will do in a temperature of 65° during the winter months, but it is not desirable to keep them in this temperature unless they are bearing a crop of fruit which it is intended to ripen. The trees can be kept much cleaner and more healthy in a greenhouse temperature.

BOILER.—W. Palmer wishes to know some gardener who has tried Messrs. Heap & Wheatly's boiler for heating a small greenhouse.

WIRING PEACH WALL (—).—The trees will not do so well with the wires fixed 6 inches from the wall as they will close to it.

ERRATUM.—Mr. Wootton Wootton, Headington House, Oxon, writes that the foot-note attached to his list of Roses on page 302 should read as follows:—La Rosière has not been sufficiently tested to compare with Prince Camille de Rohan, nor has Marguerite Brascac as regards Charles Lefebvre.

VIOLETS.—We have a letter for "G. E. M.," which can be forwarded if we receive the full address.

COVERING PEACH TREES WITH GLASS (Kittie).—Of the three plans we prefer No. 2, and if the glass lights at the top were made to lift up with a rod, which could easily be managed, it would make a most efficient covering. The sashbars ought to be 2½ inches deep by 1½ inch wide. No. 1 plan would answer equally well, but we object to the wood top.

STRAWBERRY TREATMENT (A. B. C.).—By your letter we fancy yours is rich light soil, as such soil has a tendency to cause the production of leaves minus fruit. The runners were too late in being planted to bear fruit last summer. Another reason may be in the fact that you have not good varieties. Let your beds alone this winter, but obtain some runners of such sorts as Keens' Seedling, President, Auguste Nicaise, Due de Magenta, and Frogmore Late Pine, and plant in another portion of your ground; then look out in "Doings of the Last Week" for instructions as to future treatment.

REHOBODENDRONS NOT SHOWING BLOOM BUDS (Idem).—You did wrong to pot them at the time you did; it is best to pot after the bloom buds are formed. They will not be likely to form them now.

MAKING VINE BORDER (A. N.).—The roots sent were dried up, but we did not notice any disease upon them. Nothing could be worse to put in the bottom of a Vine border than "old oak stumps," and your proposed compost is far too rich. Two cartloads of hotbed manure is enough to mix with sixteen of decayed turf; to it add two cartloads of lime rubbish and 2 cwt. of crushed bones. You need only turn the compost twice before using it.

GLOXINIA TREATMENT (Desperandum).—The leaves are turning yellow because the plant is going to rest for the winter. Lay the pots on their sides in your house, and you need not water them until February, when it will be time to start them. Do not place the pots close to hot-water pipes, else the corm or bulb may become too dry.

REPLANTING AN OLD ORCHARD (Subscriber).—As the ground under the old trees has been for so long meadow land we advise you to trench the soil before replanting it again with young trees. If you do this we are confident that they will do well. Add manure at the same time if the ground requires it.

REMOVING A PEAR TREE (E. B.).—If the tree has not been disturbed at the roots for twelve years we would make a semicircle round the roots at 4 feet from the stem, then dig a trench about 2 feet deep and work a foot nearer the tree, raising the roots, and after placing some turfy loam amongst them fill-in with the ordinary soil; the tree may then be removed next year in November. It will be found to be a mass of fibrous roots where the loam was put in.

TREATMENT OF IMANTOPHYLLUM MINIATUM (Subscriber).—This plant is usually classed as requiring greenhouse treatment, but it does better with a little more heat than the ordinary greenhouse temperature. Your plant may be too much shaded under the Vines in vinery. If it was placed near the glass and enjoyed more light it would flower. It succeeds well potted in turfy loam, a little leaf soil, and sand added to it.

ALTERATION OF VINERY (J. W. L.).—It will be quite necessary to have the ventilators at the highest part of the roof. You must therefore cut the long rafter at the point B, and use the bottom part for the short lights at the back.

TRANSPLANTING ROSES (J. P. H.).—It will of course be best to transplant your newly budded Roses to the permanent positions; the only reason for hesitation is the unornamental appearance which they will present for the next year or two. Cut back the Manetti stocks to within 2 or 3 inches of the bud immediately, and carefully remove all stem buds and suckers when they are taken up. "Rivers's Rose Amateur's Guide," D. Thomson's "Handy Book of Fruit Culture under Glass," and our own manual of "Fruit Gardening for the Many," are the works you require.

TRELLIS FOR ROSES (C. T. S.).—Stout galvanised wire strained from eyelets or staples driven into the mortar answers admirably. They may be strained up and down with cross wires in the form of squares or diamond-shaped, fastening every two wires with wire thread at every angle, and driving in a few intermediate staples to stiffen the central parts. A handy man can do a large space in a few hours with a pair of nippers and a hammer.

FLOWERS FALLING PREMATURELY IN A CONSERVATORY (J. C. M.).—When Camellias that are planted in a bed in a house so well ventilated as yours is shed the flower buds at this season of the year there is something wrong in the soil, the bed, or the watering. Camellias answer in loam, in peat, and also in a mixture of both, with enough grit or other hard substance to afford a quick and ready passage to water, care also being taken to drain the bed. When this is well done you can hardly give too much water; but if the drainage be at all inefficient, then bud-dropping and yellow foliage soon follow. The fact that plants in pots also shed their buds soon after they are brought into the house points to overwatering, and we should not be surprised if you find that somebody has amused themselves with a waterpot in your absence. A hot dry atmosphere induces bud-shedding among greenhouse plants. Camellias require no artificial heat, only for the exclusion of frost.

WINTERING ACACIA LOPHANTHA, &c. (Sambo).—*Acacia lophantha* lives through the winter in the open air in the Scilly Isles, and it would probably do so in some parts of Devon and Cornwall, but in all other parts of this country it must be taken up at once and put in a greenhouse or pit. In the public gardens of London a fresh stock of it is raised every spring from cuttings or seeds, young plants with clean single stems being found most useful for bedding purposes. A packet of seed can be had for 6d. Scented Verbena (*Aloysia citrodora*), may frequently be met with in the south in snug corners, and trained to sunny walls, where it exists and flourishes for many years. Under less favourable circumstances it must have the shelter of a frame or shed in winter. Fuchsias may be left out if the crowns are protected by a little heap of coal ashes; but as by this method the whole of the stems are usually cut down by frost, it is far preferable to lift them and put them in any shed, cellar, or frost-proof building, covering the roots with sand. We have seen them wintered successfully by covering up the entire growths, roots and branches, in a heap of leaves from autumn till spring. When this is done care must be taken to remove the leaves from the branches before the new growth appears, or much of it will be broken off.

PLANTING BULBS IN OPEN BEDS (Idem).—Lilies of all kinds may be planted from the present time till March. If the soil is poor and thin deepen and enrich it, planting the bulbs quite 4 inches below the surface. Hyacinths and Tulips answer best when planted in September and October. Both may, however, be planted successfully till the end of the year.

INSECT (Rosa).—Smith in his "Ferns British and Foreign" says, "Within the last twenty years a small white-winged insect like a midge has made its

appearance (supposed to have been first introduced with imported plants to Kew). They congregate on the under side of the fronds, and when the plant is moved dart off like a flock of white Pigeons. At first it was supposed to be harmless, but such is not the case, as it has been found to feed on the cuticle like thrips. Repeated tobacco fumigation destroys it." We have found it on the under side of leaves more especially the Tobacco plant (*Nicotiana*), also on *Rivina levis*, *Panicum plicatum*, *Oldenlandia Deppiana*, and *Nephradium molle*; but these plants were growing in a Cactus house where the atmosphere was rather dry, while houses in close proximity in which Ferns were growing, and the atmosphere always kept very moist, have even been quite free from the insects. The name of the insect is *Aleyrodes vaporariorum*.

NAMES OF FRUITS (J. Woodliff).—1, Beauty of Kent; 2, Bedfordshire Foundling; 3, Bess Pool; 4, Braddick's Nonpareil; 5, Golden Russet. (*South Devon*).—1, Devonshire Buckland; 2, Hunt's Deux Ans; 3 and 4, Emperor Alexander; 5, Wheeler's Extreme; 6, Not known. (*Joseph Robinson*).—Golden Noble. (*New Plant and Bulb Company*).—2, Wormsley Pippin; 3, Melon Apple; 8, Downton Pippin; 10, London Pippin; 13, Golden Reinette; 14, Lady's Finger. (*C. J. B.*).—Dumelow's Seedling. (*Connaught Subscriber*).—Nelson's Victory.

NAMES OF PLANTS (J. P.).—*Echeveria glauca*. (*G. A.*).—1, Fuchsia procumbens; 2, *Pellaea hastata*; 3, *Oncophium japonicum*; 4, *Pellaea rotundifolia*; 5, *Asplenium Adiantum-nigrum*. (*O. C. H.*).—*Cattleya Loddigesii*. (*Gratus*).—1, *Pyrethrum frutescens*; 2, *Pierardia coronaria*? (*Zebra*).—1, *Phyllis Alkekengi*; 2, Specimen insufficient. (*W. Crowder*).—*Limnathes Douglasii*. (*Rev. T. A. Brennan*).—The specimens were not numbered. The Editors cannot answer by post. (*Richard Carnall*).—1, *Eucomis punctata*; 2, *Chrysanthemum fruticosum*; 3, *Hyssopus officinalis*.

POULTRY, BEE, AND PIGEON CHRONICLE.

THE CRYSTAL PALACE SCHEDULE.

THE schedule is out and the entries are supposed to have closed, but Mr. Howard has announced that the Committee have decided to keep open their entries until after the results of the Oxford Show become known, and that entries will be received until the 29th inst. Outside and inside the little book is so much as usual that the notices of past year's schedules will almost suffice for this. The highest value of any one poultry cup is £6 6s., and some more money has judiciously been offered for old birds, such as Buff Cochins, &c. We are, however, sorry to see that the class for Silkies has been omitted, especially when many fanciers of long standing have this season joined their ranks. It is true they only mustered seven pens last year; but if this is why they are now cut out, with their departure should have gone too classes for Silver-pencilled Hamburg cocks and Silver-pencilled Hamburg hens, White Leghorn cocks, &c. A national show should surely comprise the best classification extant, and not drop out a class save under exceptional circumstances. We must also again express our disappointment that the untrimmed class is allowed to remain; but we do not blame the Committee one-half as much as the exhibitors generally, for there were twenty-nine entries last year, and that means £10 17s. 6d. in entry fees, and as the cup was given only £2 came from the Society's funds, and they therefore netted £8 17s. 6d.; but we do wonder such exhibitors as Messrs. Leno, Petter, Beldon, Lingwood, &c., competed. Was the class only for "Vulture-hocked Asiatics" we would welcome it gladly.

Langshans have a class and a cup presented to them by their champion. We wonder if Black Cochins from a Black Cochins yard will obtain it. It is truly ridiculous to find what fanciers think of this title, and to see how Black Cochins generally win the club's prizes or those given by their supporters. An exhibitor whom we know recently won the Langshan cup at a show, and wrote to us afterwards thus:—"The Langshans I must tell you are the expiring effort of my Black Cochins. Having determined to get rid of my whole stock of them, and to please one of the Committee I sent a pair to that Show in the Langshan class, hoping they might sell. I was rather dismayed at their success, and shall be very glad to be quit of them all." Among the other classes we want to say a word for the Turkeys. They have three divisions here, and we do hope the pens will be properly divided and that we shall see no more of those sanguinary fights as we did at the Dairy Show, where two lady exhibitors had to go out to buy canvas wherewith to divide their pens more securely, for the cocks were utterly ruining each other's appearances by fighting; and their pens too should really be larger, for the one in which Mrs. Wyke's Turkey cock was at Islington could not hold him. And we do sincerely hope the Turkey chicken classes will only have poult this year in them, for we can all remember what many said last year when old birds were supposed to have won prizes for chickens, and how the protest was, we believe, not noticed by the Committee. We are very glad to see the managing body have made a concession regarding the double baskets, and after the unpleasant facts of last year's disqualification they have done most wisely in stating in their sixth rule that when fraudulent practices are subsequently discovered the prizes will be withheld.

The Judges are much as usual, though the Rev. C. C. Ewbank and Mr. Maldon have been engaged for the French and Black Ducks. We should greatly have liked to have seen a larger amateur element; one for Dorkings, another for Cochins, and another for Brahmas would have amply repaid, we are sure, in

entries any extra expenditure. We should much like to know what each Judge will do, and cannot understand why this should not be known, for a mere string of names is as useless as none at all.

There are a few new Pigeon classes, and there appear to be lots of new Pigeon fanciers, so we hope the classes will obtain very many entries. The collections of four pairs of Pigeons other than Carriers, Pouters, and Tumblers still remain, and always make to our mind a great feature of the Show. Mr. Howard is still the Secretary, and Mr. Crook the Treasurer; the names of the remainder of the Committee do not transpire, but the schedule of rules and regulations is signed by their order by Mr. Howard. We have every confidence of a great show again, and we shall be delighted to see such an one; and the sight of some of last year's inmates of the Palace interspersed with the chickens of this season will be very pleasing, for in the number of the past chicken shows we seem to have quite learnt to know the peculiarities and appearances of most of the youngsters, though, of course, many will appear here which have never before seen the walls of Messrs. Turner's and Billett's cages.—W.

MOULTING FOWLS.

THE moulting season is the most critical period of the year for old fowls; and yet in ninety-nine cases out of a hundred there is less care taken than in the spring, when everything is in their favour. The idea seems to be, that now the young stock is out of harm's way, they can all shift for themselves.

Some have much more difficulty in moulting than others. Spanish are a long time naked. All the non-sitters feather more slowly than the others. It may be because they lay a greater number of eggs, and that the production of them causes more exhaustion of the system than the twenty-one days of the sitters. Certain it is, however, that moulting is an effort, and taxes the bird so much that at such a time any old weakness or partially cured disease is sure to show itself again. Thus where roup has existed in a poultry-yard it always re-appears at moulting time.

Perhaps many readers have never considered the great drain upon the system of the fowl during this change of covering. Not only have the regular flesh-forming, life-giving processes of Nature to be fulfilled, but an entire new coat of feathers has also to be manufactured. These feathers consist not of flesh and blood alone, but of component parts of animal and mineral substances. These substances are assimilated from the food, and unless birds can obtain such food as contains the necessary qualities the work drags, is prolonged, and the poor fowl droops and grows thinner in the vain endeavours to fulfil Nature's requirements without the proper means to work with. I doubt if one person in twenty has ever given this a thought, and yet it is of the utmost importance to thorough and complete success in raising first-class stock.

Birds that have their full liberty and are well fed always moult well; but when they are kept in confinement, care and precaution are generally necessary. The effects of food may be proved by a fact. Quails are exceedingly fond of hemp seed. This is of a very heating nature, and if they are allowed to eat too much of it their plumage becomes nearly black. If they are fed entirely on it, their bodies are so heated that everything is dried up and no nourishment is possible. Their feathers, like plants, die for the lack of moisture. If improper food has this effect, then judicious feeding ought to assist. When birds are moulting they must have plenty of cooling food, and there is none so good as lettuce; if it has gone to seed and stalking so much the better.

Sometimes a fowl will be seen while moulting to be continually pecking or scratching at one spot of its body. On examination it will be found that one or more feathers have failed in passing through the opening in the skin that is provided for the purpose. They keep on growing, but they grow beneath it. This causes much pain. It is common in the top-knots of Polands, but the remedy is a very easy one; take a stout needle and pass it under the quill end of the covered feather, then draw the feather from under the skin. An abundance of warming nutritious food is needed at this time, and a tonic of some kind may also be given. Stale bread soaked in old ale given two or three times a week is said to be beneficial; but perhaps one of the best things to use is one-half pound sulphate of iron (green vitriol), one ounce sulphuric acid, two gallons of water. Put a teaspoonful of this mixture to each pint of water in the drinking fountain, and keep it by them during the whole time of moulting.

One thing requires to be watched; they will sometimes, in a dissatisfied habit of body, begin to peck and eat each other's feathers. If a fowl does this it should at once be removed, as it will teach others the same habit.—(*Stock Journal*.)

BERMINGHAM CATTLE AND POULTRY SHOW.—The schedules of prizes for the above important Exhibition, which has now reached its twenty-ninth year of existence, are in circulation,

and intending exhibitors are reminded that all entries must be forwarded to the Secretary, at Bingley Hall, on or before Thursday next, November 1st. The lists have in past years been so liberally extended that little change has now been thought necessary, the premiums ranging in the cattle department from £100 down to £5 for the leading breeds, which are kept distinct throughout, besides the President's twenty-five guinea cup, the Elkington 100-guinea challenge cup, and other valuable trophies. The amount devoted to this division is close on £1200. The poultry list will be augmented by the addition of classes for Black Cochins, Leghorns, Langshans, Andalusians, and Silkies; and several additional cups are given to the Pigeons, the prizes for which amount to about £850. New Selling classes have likewise been introduced for all breeds of poultry, Ducks, and Pigeons, the entrance fees in these classes being at a reduced rate.

OUTDOOR RABBIT HUTCHES.

LIKE all other animals Rabbits in domestication require to be very carefully housed, without which they will not give satisfaction to the keeper. There are many varieties of hutches, but as a rule the simplest and warmest are the best. Sometimes the only houses provided are tubs or barrels turned on one side, and short planks nailed across the bottom to make a level floor. As they bulge out in the centre and go smaller at the ends they make very suitable hutches for single Rabbits but do not answer generally for breeding, although some of the harder varieties, especially the common Grey, will breed very well in them. The mode of construction is very simple. Instead of nailing-in the floor it is best to have the planks loose and fitted in a groove. If a space of half an inch between each be left the cleansing process will be much facilitated, as the boards can be removed and the bottom washed. For the front a square frame should be made about the size of the bottom square, the interstices being planked over. This will give both air and retirement, and will be very satisfactory. The frame should consist of wooden slabs nailed on cross pieces. The slabs should be 2 inches wide and 1 inch apart. If the Rabbits gnaw the bars, as they sometimes do, their mischief can be stopped by fixing a piece of copper wire near each edge. If preferred iron netting may be nailed over, but it is a trifle too cold for an outdoor hutch. Perhaps the best of all are iron hoop bars, which may be nailed on as the wooden ones. They cannot be gnawed, and they tend to strengthen the frame very much. The top of the tub should be covered with felt to keep the wet out, and it will be found economical to tar or paint this, as otherwise it would soon rot and want renewing. It need not be nailed down, but is better laid on loose, so that it can be shaken occasionally and thus kept free from vermin. The framework referred to, and which is much the same for all outdoor hutches, should be very strongly made. Four pieces of wood the proper size nailed together will do and last for some time, but the proper way is to dovetail the pieces together, using glue and a screw at each junction. The wood should be at least three-quarter-inch or it will not be sufficiently strong. The iron bars should be put on evenly and upright. If you are short of tools take the hooks to a blacksmith, who will cut them to any length—and the lengths are easily measured and chalked—and will moreover make the holes in each for the nails by which they are to be affixed to the solid frame. For about sixpence this can be done, and it will save much trouble. If the hoops are broken to the desired lengths the edges will be rough and never look well. If it be desired to do matters extra well, and so as to be very durable, the bars should be screwed on. Great care should be used not to split the frame, and if a little red lead be put in the screw holes it will be well. Of course one screw each end will be enough. If preferred the bars may be put between two pieces of board for the frame, and the two pieces screwed together. There is some difficulty in putting them together like this, but they will last a very long time if once well done, although for ordinary wear and tear it is not necessary. Barrels are sometimes merely stood on end under a shed and used as hutches. This form is very useful for a day or two on a sudden addition being made to the rabbitry beyond the strength of the hutches, but it is not to be recommended for several reasons. Not only does it look untidy and unfinished, but it also places a great temptation in the way of cats. Besides this there can be but little comfort for the Rabbit and the waste of space is enormous, the height being so much more than can be necessary. Still, as previously remarked, there can be no objection to a temporary hutch being formed in this way.

A good strong case—such as can be bought from egg-importers, grocers, and others—will make a capital outdoor breeding hutch, and a very inexpensive one into the bargain. A wire case is the best, but they are generally very expensive. I once had one made of 1½-inch boards with each plank dovetailed into the next, so that it was both water and damp proof. It was given to me, but I think it would cost at least half a sovereign. A suitable case can be purchased for much less than a quarter of that sum. Let the length be from 2 feet 9 inches to 3 feet 6 inches,

the depth from 1 foot 6 inches upwards, and the height a foot or upwards. In any event there will be a few little holes which should be seen to. It is best to nail a slab over any hole. If the wood is thick this course will be quite sufficient; if, however, the thickness is only half an inch it is advisable to nail a thin slab along each joint and a thick slab crossways. If a few bands of iron be used it will also strengthen the frame, a necessary precaution if the hutch is ever likely to be removed. The next thing will be to provide a nest place for the young. The way to do this will be to divide the hutch into two parts, one of which should be at least double the size of the other. The partition should be of thick boards, say an inch or $1\frac{1}{2}$ inch; this will be a great strengthener to the hutch itself, and will keep the top in its place, otherwise it will be a little liable to fall in, in which case the front will not open well. There will have to be a hole for the Rabbits to get through—a circular one about 5 inches in diameter. The edges should be rounded and tinned to prevent gnawing. The frame will have to be the exact size of the outside portion, the door for the smaller being made small for the purpose of increased warmth and privacy. The floor should be planed as smooth as possible to facilitate cleaning, and the harder the wood the better will be the result. A small rack should be put up at the corner farthest from the sleeping compartment to hold hay and green stuff. This will keep it clean and dry and save a great deal of waste, as the Rabbits do not care about food after it has been trampled upon. The roof should be protected to keep the wet out. A second layer of boards is perhaps the best plan, and the next is to nail a piece of carpet or felt over it. In any case the top should extend a few inches beyond the front to prevent the rain from beating in.

A shutter should also be constructed the exact size or perhaps a little wider than the front. This can be let down at night or in wet weather, and if a padlock be used will be some protection against biped and quadruped nocturnal marauders. The whole of the outside of the hutch should be well painted with two coats of good brown or buff paint, and the inside should be whitewashed. Both should be renewed every spring, and the hutch will be found to last longer if this matter be well attended to.

In selecting a place for an outdoor hutch a high fence or wall should be preferred, as by that means both wind and rain will be kept off. A corner at the junction of two high walls is very good.—GETA.

IMPORTATION OF EGGS.—Last year the value of the eggs imported into England was £2,612,231, but even this large importation failed to satisfy our requirements, and the high price of eggs in the market at the present time shows that we can buy more and eat more if we can only get them. It seems probable that substantial help in this as in other matters relating to food supply will come from the other side of the Atlantic. Canada is establishing an egg trade with us which promises to assume important dimensions. Last week one steamer alone brought to Liverpool from Canada 250 barrels of eggs, and there is every prospect of a continuous stream of eggs setting in from that country. The Canadians cannot, in fact, keep up their hens, who lay more eggs than the colony can consume. The market report of the Hamilton (Ontario) *Spectator* of the 9th of August mentions that eggs were "very quiet," there being really no wholesale trade in them at present. In Ottawa fresh eggs were selling at 12 cents—that is, 6d. a dozen. Eggs at this price would be a boon to the British housekeeper, and might take the place of meat, in which case there would be less grumbling and gout.

ARTIFICIAL FOUNDATIONS.

OUR transatlantic friends quite transcend the British bee-keepers in experiment and invention. Almost every modern invention in bee-keeping is an outcome of American activity, and comes across the Atlantic Ocean to us. While we are hardly half awake to the possibility of improvements the American apianians compass and perfect them. While John Bull is putting on his boots our friends across the water can travel across a continent. The American bee-keepers have bluer skies and warmer summers than we have, and therefore have greater encouragements to make exertions and experiments. The exertions made do not all end in important discoveries, and many of their inventions are of no practical value. The impressed sheets of wax called "comb foundations" are in my humble opinion the best things that ever came from American bee-keepers to this country, as they are likely to be extensively used when their practical value becomes known. What I now say is nothing more than opinion, for I have not tested by experiment the worth of comb foundations introduced into hives. A few weeks ago I asked Mr. Hunter of Ealing to send me a small bit of foundation comb for examination. As this year's consignment had not arrived, he sent me a bit of last year's lot, which came safely by post, and which I admire much. It is a capital imitation of natural comb, so perfect in form and manufacture

that every apianian who examines it cannot avoid admiring the ingenuity and machinery which produce it. It is rather darker in colour than natural virgin comb, and I fancy the walls of the cells are slightly thicker and contain more wax than natural comb. In a note accompanying the small piece of comb foundation referred to Mr. Hunter says that "this is rather a thin sample as readily accepted by the bees, but not so quickly worked-up into comb, the bees having to supplement the supply of wax from their own resources. The sheets are made from 4 to 9 square feet to the pound, the heavier furnishing ample wax for the bees to complete the combs."

The value of these wax foundations to the bees and bee-masters is still, of course, an open question, and doubtless various and differing conclusions will be come to by apianians when extensive experiments are made with them. All I can say at present is that I have formed a very favourable opinion of them, and that if the bees take to and adopt them readily they will be useful in many ways, especially in supering. But comb foundations meant for supers should be made of wax well bleached, and made as white as possible. We all know that wax, like flax, is bleachable. If bees readily adopt comb foundation bee-keepers will find it an easy matter to entice their bees to commence work in supers. A few large pieces of foundations fitted in supers and running from tops to bottoms will serve to draw the bees into them as soon as the hives on which they may be placed become full. For swarm hives meant for stocks comb foundations of a darker colour, or made of wax not so well bleached, may be used. For swarm hives nothing but bee comb foundations should be introduced, and for supers nothing but drone comb; the reasons for so doing are easily understood.

By using two or three sheets of foundations in swarm hives it is likely that all the eggs queens may lay after swarming may be set for brood. When swarms are placed in empty hives the bees have not cells enough for the eggs laid by their queens, and almost invariably place eggs in cells before their natural foundations are well laid. The walls of the cells in swarm hives are frequently built up and around the eggs placed on their foundations, and doubtless if artificial foundations answer the end for which they are made eggs will be set in them before they are completed. I will not venture to say more about these American sheets at present. My object in noticing them now is to help Mr. Hunter in calling the attention of bee-keepers generally to them. According to the statement made by Mr. Hunter in this Journal a few weeks ago the price of these sheets of comb foundations is very moderate indeed—2s. 6d. per pound if I remember rightly. My wax in the lump and unbleached sells readily at 2s. per pound. If it be found by experiment, ample and satisfactory, that bees readily adopt the artificial foundations and work them up into combs, we may safely predict that they will be extensively used by the bee-keepers of Great Britain and a very good account given of them.—A. PETHIGREW.

LIGURIAN BEES.

Mr experience of Ligurian bees is not very great, extending only over the past season, but during that time I have endeavoured to make myself as much acquainted as possible with their peculiar excellencies or deficiencies. A Ligurian queen was sent to me by Mr. Abbott towards the end of May. From a very large skep, holding about a bushel, I drove a swarm and introduced the stranger queen to the driven stock. She was received amicably, and at once proceeded to deposit eggs in the thousands of empty cells. Nine days after a powerful swarm was led-off by the Ligurian, and it joined itself to another swarm from a neighbouring hive. By casting all the bees upon a white cloth a yard or so in front of a bar-frame hive I managed to catch both queens under wine-glasses. I returned the black queen to the hive whence she had led the swarm, and to make all sure I placed the Ligurian for twelve hours in a cage and inserted it between the frames. She was duly released, and next day had deposited lots of eggs. Young Ligurians appeared twenty-six days after at the mouth of the hive. I had seen them first on the combs twenty-two days after the insertion of the queen. Gradually the powerful black colony died-out, and the third week in August none but yellow bees inhabited the hive excepting a few drones, which were soon after expelled. Meantime the Ligurian princess was proving herself a worthy successor, and young bees hatched-out after all those which must have been the progeny of the pure queen appeared to me to differ nowise from their older relatives either as to size or colour, although the young queen must have been fertilised by a black drone. Both hives made honey while the sun shone, and I was able to take a sectional super with five sections complete, and two nearly filled but not sealed, from the bar-frame hive before the honey season ended. Weight of seven sections 16½ lbs. Every frame, ten in number, was filled with beautifully built comb, started upon a guide of worker pattern mid-rib 4 inches deep. These combs are perfection for the extractor, all straight as a line. Four were taken out and given to a weaker stock, and I have kept my yellow-jackets busy fixing old

empty combs for me in frames, to use next spring for early swarms. They have abundance of honey in both hives for winter consumption, and breeding has been kept-up late by giving a small but constant supply of barleysugar. All my stocks are so fed in autumn. Syrup given at that time only supplies a superfluous amount of liquid, which is evaporated and renders the hive damp at a time when it cannot be kept too dry. Of course syrup must be given to increase rapidly the stores of a weak stock, but for gentle stimulative feeding I prefer barleysugar; the bees cannot take this too fast. I make a number of rough little boxes without bottoms or lids, about 4 inches square. In the place of bottoms I tack on a small piece of perforated zinc, that used for supering, and a small square of druggot or any warm covering is laid over the box. Thus all moisture escapes; the barleysugar is put into the box which is placed over the feeding-hole in the quilt, and the bees fetch it gradually, in quite sufficient quantities to stimulate the queen to continue laying.

But what was I writing about? Ligurians? Yes. Are Ligurians more energetic in searching for food, or have they the powers of scent more fully developed than our black bees? Whether it be the one or the other it matters not. If we can prove that they find food much more quickly than the black bees, then we at once find in them a recommendation to our favour. Let anyone with both black and yellow bees in his garden test this point for himself. I have done so a score of times. Place an unfinished super, a piece of comb with honey in it, or some scented syrup in a place unfrequented by the bees, say under a cabbage in a bed of that vegetable, and note the first bee that visits it. In nine cases out of ten it will be a Ligurian, and among the first dozen bees that pilfer the sweets there will be eight or nine Ligurians, or hybrids, as the case may be. Some have found their Italians much more irascible insects than the black bees. I cannot say that I find any difference in regard to disposition. Both kinds can be readily made perfectly docile by being first thoroughly intimidated by a puff of smoke and bribed by the gift of a little warm syrup in cases of emergency.

I find that my Ligurians visit flowers which I have never seen visited by our native friends. I have had flowers of *Tacsonia Van-Volxemii* blooming in my conservatory nearly all the year round. My bees have always visited the primulas, heaths, cyclamens, and many other flowers, but until I had Ligurians I never saw a bee on the *tacsonia* blossoms, neither on the flowers of the *tritoma*. Again, what insinuating rascals they must be. In seven different hives, when inspecting them previous to their going into winter quarters, I saw Ligurians. How they had got there and why they went there I leave others to answer, but not a single black bee can I find in my Ligurian and hybrid stocks. This fact tells me that they are more audacious and at the same time more tenacious of their own rights than their sombre sisters. Altogether I find myself, although only at the close of my first year's acquaintance, becoming a lover of the graceful Italian, and when I compare her with her Anglican sister I must say that I find my predilections strongly biased in her favour.—P. H. PHILLIPS, *Offley Lodge, Hitchin.*

CAN BEES EAT POLLEN?

"Do bees eat pollen?" is a question that was put and answered in this Journal some months ago. Can bees eat pollen? is a more difficult question to answer. Those who have studied the structure of the bee, and have made anatomical investigations of its head, are perhaps best able to answer this question. If any apian prove that bees eat pollen an anatomical examination will be quite unnecessary. The fact will establish the power. It is known that adult bees do live and are healthy for months without pollen; it is also known that pollen or bee bread is largely consumed by bee grubs before they pass into the chrysalis state. It is well known, too, what ravenous creatures caterpillars are, and how soon they skeletonise cabbage blades and gooseberry leaves; but after the caterpillars reach maturity and appear as butterflies they do not eat cabbage and gooseberry leaves. Bees and butterflies evolved and matured from maggots and caterpillars are altogether changed. After transformation do they possess organs and instruments for mastication? A bee-keeper in Scotland once told me that he soaked a boiled potato in syrup and gave it to a hive, and that the bees ate every bit of the potato. A Cheshire bee-keeper says he boils honey and pollen together for his bees, and that they thrive on it. I did not believe the Scotchman's story, neither do I believe that the bees of the Cheshireman swallow pollen. Often enough have I given honey polluted with pollen to bees, but never found them to fail in filtering the honey into their hives and leaving the pollen as dust in the vessels in which it was presented to them. Some three months ago I soaked a boiled potato and broke it up in syrup in a saucer which was placed on a board not quite full of combs. The bees took the syrup and well drained the potato, which lay next morning in the saucer dry and tasteless. Some time ago a gentleman in Altrincham told me he bought some honey of a grocer or chemist of that town for his bees, and gave

some of it to them in a trough. Next morning he found the bottom of the trough covered with flour. The grocer was told that his honey was impure, but he did not think it was so, and filled a clean trough himself and gave it to the bees. He returned next morning to examine the trough, when he found it covered with flour. In the face of these facts the question is asked, Can bees eat pollen?—A. PETTIGREW.

OUR LETTER BOX.

FOWLS IN CONFINED SPACE (*Hamburg*).—In a space 80 feet by 60 you may keep thirty stock fowls. They would not injure the trees planted in their run.

MARKING FOWLS (*W. B. P.*).—Nothing is easier than to mark poultry by putting a wire ring or sewing a piece of list round the leg, and this last is capable of development by enabling those who wish to do it to mark the different broods by using worsted or list of different colours. There is always difficulty in telling the age of hens. A very good judge may feel tolerably sure and justified in giving an opinion, but if he were asked to name the grounds on which his decision was based he would be unable to do so, and would hide behind generalities.

DUCKS BREEDING (*Mrs. W.*).—Ducks require water in the breeding season. They do perfectly well without it at any other time. The Aylesburys are the best layers, but they do not sit. The Rouens come next, and then the Buenos Ayrean; these last lay and sit well; they are also hardy. Your Light Brahmas will not lay before September, and that will depend somewhat on the weather.

REMARKS.

- 17th.—Strong white frost in morning, beautifully fine and bright during the day, and at intervals cloudless; rather cool.
 18th.—Very foggy morning, fine day, foggy again at night.
 19th.—Rather foggy, pleasant after 11 A.M., and beautiful night.
 20th.—Very fine and very pleasant day; much warmer.
 21st.—Very dull all day; windy in afternoon and evening.
 22nd.—Windy with occasional showers; fine night.
 23rd.—Dull and thick morning, rain at intervals till 6 P.M.; fine and moonlight after.

Cooler than the previous week, but in no way remarkable.—G. J. SYMONS.

COVENT GARDEN MARKET.—OCTOBER 24.

A BRISKER market the last few days, and clearances in Apples have been more readily effected, though with no alteration in rates. Large quantities of Pears still reach us from the Continent, consisting mainly of Duchesse d'Angoulême and Bône Diel. Cobs are easily cleared at last week's quotations.

From observations taken near London during forty-three years, the average day temperature of the week is 53.1°; and its night temperature 37.0°.

GRAPES CRACKING.

OUR correspondents, Messrs. Taylor and others, seem to think they can stop the cracking or splitting in the Madresfield Court Grape. Mr. Taylor, indeed, can do it instantaneously. I only wish he would try his hand on a couple of Vines here, or reconcile their vagaries in that respect with his hypothesis on the subject.

We have two Vines growing in the same house and entirely in an inside border. One Vine is in the middle of the house, and the other is at the west end where it has the most light. Both Vines are planted in the middle of the border—that is, equidistant from the front and back walls, and one is trained down the rafters and the other is trained both up and down, a shoot diverging each way where the stem reaches the wires. Both Vines were planted in 1870, and they are moderately vigorous, but the one that is trained downwards is the strongest, and has always the finest foliage, though it has not been allowed to extend an inch for some five years, and the sap is forced directly into the spur-trained shoots, fruiting or otherwise, and which are every year stopped methodically in the usual way. The Vine at the end has been allowed to extend a foot or two, but otherwise it has been treated like the other; and with this exception the breadth of foliage developed on each every year, and weight of crop, has been as nearly as possible the same.

And now for the "cracking." The fruit cracks less or more on both Vines, but the end Vine is always much the worst. This season there was not a bunch on it that did not crack, some very badly; whereas on the Vine in the middle of the house there was not a single bad berry, so far as I am aware, and the last bunch is still hanging on the Vine dead ripe and partially shrivelled; and yet this Vine, according to Mr. Taylor, is just the one that should have cracked berries. It is the strongest Vine, has the most succulent foliage, the sap cannot go anywhere else but into the lateral shoots and those which bear the bunches, and no attempt has been made to check the growth as Mr. Taylor directs. Besides, this Vine gets considerably the most water at the root, for it has to take its chance with the others, chiefly Alicante and Lady Downe's, and we water as copiously as most people. Contrary to what it ought to do, too, the Vine at the end begins generally to go off on the bottom limb first, though it is the weakest, the sap turning by preference into the top limb in its ascent. I may just say that the crop, including the Madresfield Court, has coloured as well this season as I have ever known it do.

Leaving the problem here propounded for your correspondent to solve, I ask, in conclusion, why cracking should always be supposed to be produced by the force of the sap from within? Neither in the case of the Madresfield Court nor the Chasselas Musqué Grape does any sap flow out when bursting occurs. Before the berry cracked by distension one would expect the sap to ooze

through the pores of the skin, as it does in the case of the Lady Downe's Grape when the fruit is allowed to hang on the Vine till the sap begins rising in the spring, but it does not.

To me the cracking has always appeared to be just the same as that which appears on chapped hands and on the lips of human beings, which is caused by external cold and exposure. It is a curious fact that in the case of the Vine at the end of the house, to which I have already referred, the sun shines directly on the bunches for a long while every afternoon; whereas on the other Vine, where there is so little cracking, the bunches are much shaded, as the Vines are trained only 2 feet asunder and the foliage covers the roof entirely in every part.

If any of your correspondents can give information on this point it may throw a new light on the subject of the cracking of Grape berries.—J. S. W.

JOTTINGS ABOUT APPLES.

WITH hundreds of varieties to choose from, and half a dozen all that are really necessary, the difficulty is not to find six first-class Apples, kitchen or dessert, but the varieties that will meet our wants best over the longest season. An old servant is none the worse for being old—the reverse. With old favourites we have coupled long and tried services and other pleasant remembrances. The old Keswick as soon as ever they are big enough we can either eat, bake, or boil. For use to the middle of August plant sufficient of the Keswick. I once in the month of August heard a person engaged in the judging of kitchen Apples remark that he did not like the Lord Suffield, there was no weight in them. These are of the difficulties exhibitors meet with; an Apple in season—the correct thing—may or may not be appreciated. For use from the middle of August to the end of October plant Lord Suffield, and when it fails in having a crop Apples in that district will be scarce. For use from the end of October to Christmas plant Ecklinville Seedling, and of all Apples I do not think you will find a larger, or one more taking in appearance, or, of more importance as a surer bearer. From Christmas to the latter end of March I know of nothing superior to Warner's King, it will answer all kitchen requisites. To fill up the intervening space is perhaps not difficult, but I am so taken up with a local Apple grown in two or three places in Northumberland that I shall claim the liberty of naming it. A friend (Mr. Harkness of Allendale Town) last June sent me a present of a few as sound as when pulled; and in addition to good keeping qualities they were of good size and passable for table purposes. It is known as the Gateshead Lemon Pippin. Two others I strongly recommend are Cellini and Manks Codlin; they crop well, in fact are of our hardiest Apples, and will in a strait pass muster for eating.

And now for dessert. I place the Early Margaret first; its blossom will stand a little frost, and it is a good cropper. Follow this with Irish Peach, next Kerry Pippin, and then plant to the full extent Cox's Orange

Pippin, winding up for the season with Court-Pendu-Plat. Add to this list any for which you may have a fancy, and as far as need requires you may safely pass by all the rest. Though do not for a moment let it be considered that I hold this to be the best possible selection that can be made; I only contend that it is a good selection. In fact I rather regret to leave out such Apples as Dumelow's Seedling and the new Hawthornden.

And now about planting. When I plant a Gooseberry bush I do no more than rake a piece of soil, place the bush on the site raked, spread out the roots and cover them over like a good-sized molehill and in proportion. I prefer this to deep planting. A stake will steady a bush the first year; it will protect itself afterwards. You will have clean fruit when your neighbours' is dirty, and your bush will grow none the worse for having beneath it the increased depth of soil. With a clay bottom good drainage is the most necessary thing. If the bottom is poor, rotten, and cankerous, then you must make a sound one; one 2 feet deep will answer all purposes. I will take it for granted that any reasonable expense will not be allowed to stand in the way of good results. One ton of the best cement can be purchased at from £2 to £2 5s., and to this can be added from two to three parts of sharp sand, but test its strength for yourselves. If you get it sufficiently hard to put the soil on without injury it will keep getting harder afterwards. This secured, set to work and throw out a trench say 6 or 8 feet wide, leaving it round in the middle, and on either side put a drain tile just sufficiently deep to carry off the surplus water. Let the bottom of the trench be smooth; then take the parts of cement and sand, mix one part of each, and spread it with a plasterer's trowel thinly over the bottom; a quarter of an inch thick is sufficient. As soon as it is sufficiently hard throw back your soil, with an addition of as much burnt rubbish as you like, but let all the necessary manure be spread over the surface.—JOSEPH WITHERSPOON, *The Vineries, Chester-le-Street.*

AUTUMN PERENNIALS FOR SHRUBBERIES.

THERE is a dearth of flowering shrubs in autumn compared with spring, and wild flowers too are scarce. We have, it is true, the glorious tints of the fading deciduous shrubs and trees; but oh! how short-lived is their beauty! One little frost and a breath of wind, and all is over. Annuals are often recommended for the sides of woodland walks, but they are seldom satisfactory; even if birds, reptiles, and insects allow them to grow, most of such as will thrive in such positions have rather a weedy appearance, and by the end of summer are rather an eyesore than otherwise. Ordinary bedding plants have an air of vulgarity about them when placed against shrubs, or indeed against any good foliage, a mass of Cannas edged with scarlet Geraniums in Battersea Park this summer to wit. The colour was right, but something in the habits of the two plants did not harmonise. A few plants (not a continuous line) of *Gladiolus Brecheleyensis* in lieu of Geraniums would have made all the difference. I have nothing particular to say against bedding plants so long as they are kept to the beds, but bedding plants in mixed borders, subtropical beds, or around and amongst shrubs, are about as incongruous as winding walks and London rockeries in a vegetable garden. There is, however, something about the better class of herbaceous plants which claim our respect if we are not too bigoted. A plant here and there suitably placed can be made to look like part and parcel of the whole concern rather than like interlopers or tenants-at-will. Those I shall name are such as will almost take care of themselves when once well planted, needing no protection, no guarding from insects, and little or no tying-up.

It must not, however, be supposed that all herbaceous plants need so little attention. There is no place in the flower garden which takes up so much time as the herbaceous borders where there is anything like an attempt to keep them in good order; and besides this, ordinary labourers and young gardeners can hardly be persuaded to take an interest in this class of plants. With regular lines and bright colours the superintendent's work is light, but to have herbaceous or mixed borders well attended to there must be someone in charge of them who has some pretensions to the possession of taste as well as a little aptitude for learning names. The following are taken at a glance along the borders as those which are likely to stand the roughest treatment, and yet they are all really good. It would be an easy matter to extend the list, but many of the prettiest

plants have such horrible long ugly names that there is a danger of frightening beginners with an extended list.

The queen of hardy border flowers is of course *Anemone Honorine Jobert*, also called *A. japonica alba*, but it certainly is not a white variety of *A. japonica*, as it is distinct in foliage and habit. *Anemone vitifolia*, also called *A. hybrida*, is a pinkish variety nearly equal to the above, and growing to the same height—about 2½ feet. *Anemone japonica* is also very beautiful, but it does not succeed with me as well as the other two; it, however, grows well in most places. I think all three of them, though they look well almost anywhere, are best as specimens about 2 feet through on the grass.

Tritomas or Torch Flowers are suitable for similar positions, and the effect of coming suddenly along a winding walk to a large patch of *T. Uvaria glaucescens* backed by dark green foliage is almost startling. *T. grandis* is a later and larger variety, flowering from October to Christmas. Its flowers are equally as bright as the preceding, but they are not quite so freely produced.

All kinds of Lilies are admissible in the shrubbery. Most of them, perhaps all excepting *L. candidum* and its varieties, do best in light soil which does not hold too much wet in winter. Peat suits them admirably, and they can generally be grown along with American plants. *Lilium speciosum* (syn. *lancifolium*) and *L. speciosum album*, *L. punctatum*, *L. eximium*, *L. excelsum*, and of course *L. auratum*, are specially to be recommended for such positions. *L. tigrinum*, *L. tigrinum Fortunei*, *L. aurantiacum*, and the Martagon Lilies, are not so particular about the texture of the soil.

Helianthus multiflorus and *H. multiflorus plenus* are very telling perennial Sunflowers, growing 3 to 4 feet high and flowering all through the summer. *Patrinia scabiosifolia* is something like a single Sunflower, growing the same height, and is extremely pretty. The Golden Rod, *Solidago multiflora*, also growing 3 or 4 feet high, and the dwarf variety named *S. reflexa*, are very showy without being vulgar-looking. *Monarda*, generally called Bergamot, have perfumed foliage as well as handsome flowers suitable for cutting, and the best is *M. didyma* (syn. *M. Kalmiana*), a bright scarlet about 18 inches high. *Achillea Ptarmica plena* is an attractive pure white flower, very useful for cutting, and almost always in bloom; it also grows about 18 inches in height. *A. aurea* and *A. Millefolia rosea* are likewise good.

Among Michaelmas Daisies (Asters) are a great many weeds not worthy of cultivation, but on the other hand there are some varieties which are very beautiful, and these are as easy to grow as the most worthless sorts. To my mind the best of all is *A. longifolius formosus*, a rosy lilac, very free-flowering variety. *A. Amellus* is a large-flowering purple variety of dwarf habit. *A. horizontalis*, called here "Farewell Summer," is also very pretty, and so is *A. pendulus*. *Galatella cana*, 3 feet high, with small lilac flowers similar to an Aster, is good, and so is the dwarf variety called *G. hyssopifolia*. *Schizostylis coccinea* is a beautiful *Gladiolus*-like flower, but it is rather late in opening, so that, excepting in sheltered situations, it is liable to be cut off by the frost just as it is coming to its best. It is a fine plant for autumn work in pots.

Amongst other plants I have jotted down as suitable for edges of shrubberies are *Polygonum Brunoni*, *Tritonia aurea*, *Colchicum byzantinum*, *C. autumnale album*, *C. autumnale plenum*, *C. autumnale striatum*, and in fact all *Colchicums*; but autumn *Crocuses* are not so safe where there are rats or mice. Funkias, too, are good for this purpose; *F. Sieboldii*, *F. Sieboldii variegata* and *ovata*, are among the best. *Sedum Fabaria*, *Phygelius capensis*, and the Monkshoods, *Aconitum Napellus*, *A. Napellus bicolor*, and *A. autumnale*, are also hardy and showy.—WM. TAYLOR.

VENUS'S FLYTRAP.

THIS is a most interesting little plant, and one that should be more extensively grown than it is at present. I was visiting a friend at Preston, Lancashire, last year, and was taken by him to look at a collection of plants belonging to Mr. Foreshaw, an enthusiastic amateur of that place. There were many very good plants in the stoves and greenhouses, but the one that arrested my attention most was a beautiful pan of the *Dionæa muscipula*, or Venus's Flytrap. This year I saw that the same plant, or rather pan containing a number of plants, was exhibited at the summer show at Preston and was much admired. Some of our best gardeners, and amongst them Mr. Baines, had stated that they had never seen this

plant so well grown. I wrote for information as to the treatment it received; and Mr. Lanchlan Black, who has potted most of Mr. Foreshaw's plants for the last three years, writes as follows:—

"I consider this to be one of the easiest plants to grow with which I am acquainted. Some persons fancy that it can be grown in a greenhouse, or even with the protection of a cold frame, but it will not thrive under such circumstances. The best compost to grow it in is very fibry peat, sphagnum, potsherds, and lumps of charcoal, and the sphagnum ought to be encouraged to grow on the surface. It does best in a shallow pan well drained. The plant is now at rest and will make but little growth until the early spring months, and as soon as growth commences shake all the old potting material from amongst the roots and divide the mass of plants into single crowns. The potting material should be raised above the rim of the pan in the centre, then the strongest crowns should be planted in the centre and the smaller plants nearer the edge. The best temperature in winter is one from 50° to 55°, but as soon as the plants are potted in the spring the pan should be removed to a warmer house; a Cucumber house with a night temperature of 70° answers as well as any. During the whole of the growing season a plentiful supply of water is required. During the winter season enough water should be given to prevent the sphagnum from drying. The plant should not be placed in a draughty place, and it succeeds best in a still, warm, and moist atmosphere."

Such is the result of Mr. Black's experience, and I can confirm it from some little experience of my own. I grew a plant during the summer in a case with Filmy Ferns; it is now in the Cattleya house, where it will remain until the spring, and will then be potted as above and be transferred to the Cucumber house.—J. DOUGLAS.

WINTER CUCUMBER CULTURE AT EASTNOR.

WHEN visiting Earl Somers' renowned garden recently—renowned not more by the great taste and liberality of its owner than by the well-proved ability of the gardener—I was struck with the excellent condition and great promise of the winter Cucumbers. The Grapes were nearly all cut, the Melons on their "last legs," the Fig trees barren—the barrenness of October, and the Pines appearing as if halting between two seasons—summer and winter. They are grown with an object, and for a time, and that time for ripening, not now; but the Cucumbers had the appearance of having enjoyed a genial spring and were entering on summer instead of having been guided through autumn and on the eve of winter. They were so fresh, clean, strong, and springlike as to demand a note, a note of high commendation; a seasonable note too, for do they not teach an useful lesson at a seasonable time?

A mere sight-seer, I mean one of the many who admire flowers and enjoy fruits even when growing, but who are not initiated into the modes of cultivating what they inspect, would perchance see little to admire in the Cucumber house at Eastnor in October. Even the young enthusiastic professional impatient to make a name and a mark, might not be entranced with the steady, yes steady (mark the word), practice of a Coleman in growing Cucumbers on the threshold of winter. Probably when the ardent youth lived at so-and-so, had full charge there, the trellises were laden with fruit at this season of the year, but at Eastnor only a few Cucumbers were to be seen! That is just the point, the important point too, in winter Cucumber culture. Better, far better, than a crowd of fruit was the stout natural-looking foliage and the thinly-trained shoots: more attractive than a fruit-laden trellis were the vigorous white roots creeping out of one turf and into the next, so active that in fancy one might almost see them move. That is the condition in which Cucumbers should be now from which fruit is expected from November till March.

Strong early growth, a well-covered trellis, yet the shoots thinly disposed, leathery foliage bright and clean, active healthy roots bridging air spaces between turfy soil, and little or no fruit, should be the October standard for winter Cucumbers. That was their state at Eastnor on the 22nd ult. Evidently the temperature, ventilation, and atmosphere had been well managed: the soil, too, was simple yet effectual, and forbearance had been exercised in restricting the bearing of the plants. Precocious fruitfulness is the bane of winter Cucumber growing. The resources of the plants require to be husbanded now so that they may have a store of strength for the dark days, not expended in producing an early sensational crop,

and consequently weakened when the strain upon them is at its maximum.

It is some time since I saw the soil used for Cucumbers so simple and so good—that is, so rough, as at Eastnor. In its roughness consists its chief excellence. It is simply turf, turf no doubt pared from good soil, yet simply turf and used just as it was dug in large squareunks. It is surprising how little of such soil is required to grow Cucumbers when it is rightly used. There overhead was a large trellis quite covered with shoots and foliage of the most satisfactory kind; below a narrow ridge of turves, the roots protruding through them in all directions asking for another thin casing of the same sustaining and enjoyable food. Periodical layers of turves, and liquid manure when the plants are heavily worked, are all the food required by Cucumbers. All they ask for is to have the turfy soil "little and often," and rough.

In the next house, a succession house, the plants were in very large pots and the growth had nearly covered the trellis. In these pots they will remain, and their rooting medium will be rougher, far rougher, than even rough turves. What can it be, do you ask? Answer, bricks, yes bricks, or perhaps half bricks, for the Cucumbers are not particular so long as it is rough. The large pots are placed on a layer of "good stuff" over the hot-water pipes. By-and-by the roots will not only be encouraged to the surface of the pots, but over them. They will be enticed over them by rich rough food. Bricks and turves will then be packed round the pots. Water will be regularly poured in, and down the roots will go to the heat, moisture, and food below, gathering sustenance as they descend; their moist, warm, dark, rugged path, and liquid manure *ad lib.* will do the rest. That is what Cucumbers like—aerated food. What they do not like is a huge mass of close soil "given all at once and done with." They do not like alternations of heat and cold, dry draughts and cold fogs, nor especially to be heavily cropped when young. They may be young and willing, but the man is not wise who permits them to exhaust themselves to make a grand show during the early days of autumn and winter. Mr. Coleman at least does not allow them to do so, and the Eastnor plants before the winter is over will prove his practice correct.—J. WRIGHT.

COMPANY SHOWS.

UNDER the above heading you have published some remarks about which there may be some difference of opinion; indeed I know the subject alluded to is regarded differently by different people, and the remarks of an "OLD EXHIBITOR" on page 303 if they are acquiesced in by many are not by all. It was suggested in the letter referred to that special horticultural societies practically "sold themselves" to "companies" who had no real sympathy with horticulture, or any branch of it which they bought for the "time being and made the best of." That is rather strong language, not pleasant to many, yet I fear that it contains some truth.

The special societies of a horticultural nature now established are one and all calculated to do considerable good by advancing the culture of that particular flower or vegetable with which they are identified. The officers of such societies are generally disinterested men, who labour to advance their object and not to trade upon it. With the supporters of those societies the case is different. It is obvious that many of them have an "eye to business." What, then, can the few disinterested managers do in such a case? They are in a dilemma. Most of their supporters "mean business" on the one hand, and the managers of companies, such as the Aquarium, "mean business" on the other. It is their duty to attract custom, and they make liberal, even spirited, bids for popularity. The special societies of a horticultural nature must have money, and their supporters would not support them if their committees "threw such chances away" as the "companies" from time to time offered. That is the real difficulty.

By many this state of things is considered unsatisfactory, and they are brought face to face with another real difficulty when seeking a remedy. Not many special societies are strong enough to be really independent, and consequently they enter into alliances which are to a certain extent incongruous. They are induced to patronise a place of public entertainment, first because of the "consideration" offered, and secondly because there is the chance of a large number of visitors inspecting the show, some of which may perchance become specialists themselves and supporters of their new hobby.

It is very easy to over-estimate the influence of mere num-

bers, and to attach a greater importance to a "central position"—a position "in town," than such an advantage (?) is worth. In the first place the "crowds" do not flock to special shows of a horticultural nature. It has never yet been proclaimed from the house-tops that the National Rose Show at St. James's Hall was a "brilliant success"—not more successful, indeed, than the Rose Shows at "the Palaces." The Auricula Show at the Crystal Palace was well attended, perhaps better than any other special show of the year, but has it resulted in an accession of members to the Auricula Society? The Carnation Show at the Aquarium was worthy of far more of public patronage than it received, for although Roses were there also, visitors were scant; and the same may be said of the Potato Show; and this, in addition, may be said in regard to the Aquarium—and few impartial observers can deny it—that a horticultural show cannot be enjoyed there during the afternoon, the only time when many visitors can attend.

It appears to me as one interested in horticulture, yet having no particular connection with any one society—that is, having no bias towards one over the other either large or small, but desirous of seeing all prosper, that the first condition to secure in a horticultural society is a horticultural status. A mere "company" alliance will not secure this, because the chief objects and sympathies of the two are foreign in their nature. What will secure it and promote what so many are desirous of seeing—true horticultural progress? I prefer putting the matter in the form of questions. Would it not be desirable for special and purely horticultural societies to be regarded as branches of a central head having branch—subsidiary—shows in alliance with that head? If it is desirable, is it practicable. —HORTICULTURIST.

THE ROSE ELECTION.—No. 4.

VOTES IN ELECTION.

THE ROSES in the following returns are placed in the order of merit—namely, the first best twelve, the second best twelve, and the third best twenty-four varieties, except where otherwise expressed:—

Mr. T. BROWN, Gardener to A. J. Waterlow, Esq., Great Doods, Reigate.

a These varieties are bracketed only for the purposes of an election, not for the Rose catalogue or exhibition box.

b This variety (35) holds its place from the good qualities of colour, form, freshness, and perfume, also beauty of foliage and certainty on the maiden Manetti, in elector's county early boxes being rarely without it.

N.B.—Dark Roses of the Boncenne school have been purposely excluded, as seldom exhibited through opening badly or burning, though admittedly indispensable when in form.

I have been particular in closing the lists of the amateurs with that of the Rev. C. H. Bulmer's, because the list and the note attached thereto, coupled with his request that it may be printed as sent, opens up a question mooted by "WILD

SAVAGE" and myself in the earlier days of this election. Finding it met with opposition, and now acknowledging that from my natural infirmity of "thickness in the clear" I did not exactly express what I meant, I withdrew the proposition, fearing it might, if misunderstood, imperil the genuine character of the election. Several electors have touched upon the topic, some merely naming one or other of these Roses, pointedly saying the vote was to be given to the named Rose, not the other; others, like my friend Mr. Beachey, enlarging on the reasons for preference of one over another, but Mr. Bulmer's list and his request bring the matter rather to a crisis. Let me state how I did act as regards these votes in Mr. Bulmer's list. In every case of similar bracketed Roses I gave the vote, for it is plain there is only one vote to be given in each case to the Rose already standing highest on the list. It so happened that Mr. Bulmer's list was nearly the last received, and so the matter was easy.

Of course all of us think very highly of our own ideas—as Sam Slick would say, "tis human natur;" but it seems to me it would be wise to settle this little point, and argue out the *pros* and *cons*. I believe that in this present election we have not, for this very reason, arrived at the correct position of these similar Roses. Granted that they can often be distinguished "one from t'other and t'other from which," yet it must also be confessed that often, more often, "Cæsar and Pompey are so very much alike, especially Pompey," that identification utterly fails as far as the bloom alone is concerned, certainly to the ordinary Rose-grower, and even, I fancy, occasionally to the very best judge. Why, then, should not, for the purposes of election, this matter be allowed? Precedent is not wanting, as in the case of Lælia and Louise Peyronny.

I cannot resist giving my opinion, based on the numerous returns I have now for some years waded through, that these similar Roses scarcely attain their right position; for instance, Marie Finger and Eugénie Verdier. I can understand a person saying, "I cannot put two Roses so similar in my forty-eight. I choose Marie Finger, it comes best;" but another reasons exactly in the same way as regards Eugénie Verdier. Here, then, are two similar Roses that receive only one vote each, whilst these same electors each vote for some dozen Roses, like Marie Baumann and Maréchal Niel, which thus score two votes. Let this be repeated only three or four times amongst forty electors, and the result will very materially modify the position they would otherwise attain.

Let me now state briefly how I think the difficulty may be met. Confession is said to be good for the soul, and I confess I erred in saying at the onset all votes for either of these similar Roses would be given to a named one; it was, in fact, taking my opinion of the merits as the correct one, and I properly received castigation for the same. I propose, therefore, that for purposes of election Lælia and Louise Peyronny; Alba Rosea and Madame Bravy; Marie Finger and Eugénie Verdier; Ferdinand de Lesseps, Maurice Bernardin, and Exposition de Brie; Baron Prevost and Colonel de Rougemont; &c.—one Rose, and that whichever the elector prefer—should be named, then the returning officer might publish his list thus:—

18	$\left\{ \begin{array}{l} \text{Eugénie Verdier} \\ 6-6-10=22 \\ \text{Marie Finger} \\ 4-4-7=15 \end{array} \right\}$	10-10-17=37	$\left\{ \begin{array}{l} \text{These figures denoting the} \\ \text{votes in both twelves and} \\ \text{the next twenty-four.} \end{array} \right\}$
24	$\left\{ \begin{array}{l} \text{Ferdinand de Lesseps} \\ 3-3-7=13 \\ \text{Maurice Bernardin} \\ 2-4-5=11 \\ \text{Exposition de Brie} \\ 2-1-4=7 \end{array} \right\}$	7-8-16=31	

Such a plan would not only show us the most generally useful of the similar Roses, and thus be a guide to those able only to have a limited number of varieties, but by the collective vote these similar Roses would all stand higher. Such arrangement would further admit into the charmed circle of the forty-eight some Roses that, as the Rev. C. H. Bulmer says, we desire to see there; for when it comes to the last few votes, how difficult it is to balance the respective merits, and how many favourites are left out in the cold—with regret, deep regret. Mr. Beachey writes, "Many of the newer Roses are so good that they cannot be omitted, and yet for old acquaintance' sake, if for nothing else, how can one have the heart to give the cold shoulder to such dear old valued and faithful friends as Sénateur Vaisse, Pierre Notting, Gloire de Dijon (I must just slip in the last-named before the door is closed), Abel Grand, Lælia, Madame Bravy, and such like?" Other

electors, like the Rev. C. P. Peach, go even further, for he adds to his list of forty-eight Roses the names of fifty-three other varieties, headed "Regret to have to omit the following." Our "Peach" is far more tender-hearted in the kernel than the fruit.—JOSEPH HINTON, *Warminster*.

P.S.—Roughly looking at this point, I think I may say that had this election been thus carried out the Marie-Finger-Eugénie-Verdier Rose must have polled at least forty-two votes, and the Ferdinand de Lesseps, Exposition de Brie, Maurice Bernardin type would have mustered forty. The former must have forced her way into the first dozen (a very welcome addition in colour), and the latter would have made a plucky effort to follow her.—J. H.

NOTES RELATIVE TO THE POTATO.

MR. ADDISON seems to think (page 225) that the disease is brought on by deterioration in the sets and careless treatment of the same rather than an atmospheric cause. I believe the truth of the matter has been well elucidated by your able correspondent "A NORTHERN GARDENER," and I add my testimony to his. I do not know what the people of England think, but I know that in Ireland we have been taught by experience to look entirely to the season and the state of the atmosphere. The most casual observer here can and does prophesy about our crop. They draw their conclusions from the season. If the sets are planted about March or early in April, and May and June set in showery, it does very well; but on the other hand, if July, August, and September are wet, it is the universal cry, "The Potatoes are in danger." This is quite true. Last season we had an example of it; from July till about the middle of September was pretty dry, but about the latter period wet set in. The Potatoes were in full growth, or at least were quite green, with no bad tubers. A fortnight afterwards we had lots of diseased tubers, caused, we believe, by the change of weather.

It has been said by some writer that the Potato disease is contagious, and that it is an error to plant for years consecutively in the same piece of ground. This is a theory which I think will not stand in the light of experience. I know plots that cottagers have been growing Potatoes in (and nothing else) for this last twenty years, and year for year there is no difference in them from those grown in the best rotation-of-crop system. Most observers have noticed that there are varieties which are more subject to disease than others, and also that it depends on the constitution of the variety, as we find all sorts having soft delicate haulms are more prone to disease than those having strong haulms of upright growth. It is, I believe, a fact almost generally admitted that it is the haulm that conveys the disease to the tubers. This being granted, if there is no disease to carry there will be none at the root; but if there is, the haulm that can best resist it will have the most sound tubers. The potency of this theory I have seen in the Skerry, the stalks of which do resist the disease long after all others are cut down, and this year, notwithstanding that all other Potatoes are much affected, this variety is almost all sound. I know it to be a Potato requiring much inorganic matter to bring it to perfection. In a lot of about thirty varieties of seedlings that we had planted in a field I observed that all haulms of a soft flimsy nature were cut down with disease about August; the tubers were very bad. The haulms of others remained fresh and firm till we were taking them up (10th of October), and the tubers were fresh and almost free from disease.

I endorse the most of what Mr. Addison says about disbud-ding seed Potatoes several times before planting. It is a terrible error in management. No doubt it deprives the sets of some of their vitality, but how it can affect or assist a malady purely atmospheric it beats me to know. I say atmospheric, as I have seen what attacks the tops of the Potatoes on several plants, especially this season, when it came on so early, while all foliage was tender. I examined the leaves of Beans, Beech, and Lilac, and to all appearance it was identical. In this matter I do not stand alone, as my employer tells me it was perceptible on many trees and shrubs in the years of 1845 and 1846.

In conclusion let me say that as the Potato is so valuable as a culinary root, it by all means ought to be grown for its quality and not for its quantity. It is to be seen in far too many cases planted too thickly, so that when about half grown they are growing into and weakening each other. I believe if we were to grow none but those having stout haulms, and plant them in soil mostly inorganic such distances from

each other that they could be seen individually all through their growth, we should have less of disease. This, I know, would be a step in the right direction. Experience teaches me Potatoes ought to have an inorganic soil, as the quality of those grown on an organic soil is never so good; besides, I know the disease always attacks them on boggy soils first. I believe the disease travels in the dense fogs that visit us through the months of July, August, and September. These fogs and aqueous organic soils have a great affinity for each other, and therefore the disease settles here first.—B. G., *Co. Down*.

THE LATE MR. RIVERS.

(Continued from page 228.)

In our last we gave a sketch of the life and works of Mr. Rivers in their general relation to horticulture. We will now consider what he has done in that branch with which his name is likely to be most enduring, and in the interests of which he did more than any other person in modern times. When Mr. Rivers first turned his attention seriously to fruit culture our orcharding and fruit-tree management were at the lowest possible ebb. The orchards of Kent which had for centuries furnished the supplies of fruit to the great metropolis had become gnarled, cankered, and unproductive. The removal of the protective duty on imported fruit discouraged the Kentish farmers; many of them grubbed the orchards they had, and those who had them not refused to plant. In this condition did the fruit-producing districts for many years remain; the old cankered orchards became older and more cankered, and no attempt was made to supply the deficiency that was yearly becoming greater. No more short-sighted policy could have been followed by the English orchardists, for by their action they merely opened a wider door to the foreign grower. With a soil and climate adapted for fruit-growing to supply our every want, we were about to be handed over to the foreign producer for the supplies which we could easily have of far better quality at home. Mr. Rivers saw the course that was inevitable, and he set himself to arrest it. He was strongly imbued with a patriotic feeling, and though sufficiently cosmopolitan he never forgot that there was nothing that any other nation could do that was not equally within the power and grasp of the Anglo-Saxon race in similar circumstances. This was a feature in his character which we often remarked, and one of the phases of it was that he never would be outdone or allow that an Englishman could be outdone by any other nationality. He used often to remark, "Why should we import fruit from abroad when we have the soil and climate to grow it here in England?" He was always impatient of the old Kentish orchardists, as he was of all laggards and dullards. He was a man of action and great foresight, and knowing that this state of affairs could not long continue he set himself to inaugurate a better way, and he lived to admire the modern orcharding of Kent.

Mr. Rivers was not a mere talker and writer, for he acted both what he talked and wrote. While he was instructing the fruit-growers of the country by his writings, he was at the same time showing them an example and instructing them by what he did. It is now many years since he planted hundreds of Louise Bonne of Jersey Pears and Early Rivers Plum as pyramids, to show what could be done on a small space of ground with trees of small size properly managed. These trees are in existence still and continue to produce abundant crops. The practice which he followed in the nurseries at Sawbridgeworth was, perhaps, of greater value than his voluminous writings, for these facts could be studied, and those who could not realise what they read by description could see the real thing before their eyes.

It was mainly in Worcestershire, in the Vale of Evesham, and in some of the market gardens round London, that the system which Mr. Rivers advocated was first practised; and the success that attended it being universally acknowledged, the Kentish orchardists seeing the advantages of the new system soon adopted it, and now in that favoured county may be seen hundreds of acres of fruit trees grown on the pyramid fashion, while perhaps a still greater extent is being planted with standard trees of superior sorts both in quality and fertility. That which aided Mr. Rivers in this description of orcharding was the use of the dwarfing stocks—the Quince for the Pears, and the Paradise for Apples. He was the first to urge an extensive use of the Quince stock, and for years he had to battle against much opposition before he could convince

the public of its importance. It had for many years been used in France, and a few were grown in English nurseries, more to indulge a fancy than anything else; but its use on a large scale was due to the unabated advocacy of Mr. Rivers, and he succeeded at last in convincing the British gardener that to grow garden fruit properly and to economise space the use of the dwarfing stocks with root-pruning were necessary.

For Apples he, like others, used the French Paradise stock and the Doucin till he found that neither was so well adapted for the purpose as could be desired. The former was a weak and delicate plant not adapted for this climate, and being fortunate in finding a number of trees among some seedling Apples which retained a dwarf habit and the peculiarity of throwing out an abundance of small roots near the surface of the ground, his ready eye detected them, and they were selected for experiments in dwarfing. One or two were chosen as being the best, and at last Mr. Rivers found that every qualification being supplied by the variety called the Nonesuch, this has now become the only dwarfing stock for Apples used in the Sawbridgeworth Nurseries. Of its excellence for dwarfing and inducing fertility we can amply testify from long experience.

It was at an early period in life that Mr. Rivers began to raise seedling fruit trees. As we have already stated in our former notice published last week his father resigned to him the whole interest in the Sawbridgeworth Nurseries in 1827, and shortly afterwards in 1834 he succeeded in obtaining two seedling Plums, which were respectively known at that time as Rivers' No. 1 and Rivers' No. 2. These were raised from the *Precoce de Tours*, an old early variety; and they were both so much earlier, more hardy, and greatly more prolific than their parent, that Mr. Rivers showed his appreciation of them by making a plantation of fruiting trees, which have amply justified his judgment and foresight by the remunerative returns they have made. No. 1 ultimately became known as *Early Favourite* and No. 2 as *Early Prolific*, the latter being now better known as *Early Rivers*; and if Mr. Rivers had done nothing else to keep him in remembrance the introduction of this valuable Plum would have been sufficient to have done so.

Shortly after he started growing fruit trees in pots the Stanwick Nectarine, raised by Lord Prudhoe at Stanwick in Northumberland, was placed in his hands for propagation and distribution. The plants were all reared in pots, and on the 25th of May, 1850, the stock, consisting of twenty-four plants, was sold by auction for £164 17s., which amount was handed over to the funds of the Gardeners' Royal Benevolent Institution. The introduction of the Stanwick Nectarine and the discovery of the orchard house combined to lay the foundation of Mr. Rivers' success as a raiser of new fruits. Without either it is very probable that the many new Peaches and Nectarines which have added so many delights to our gardens would never have existed. The Stanwick gave a new character to the fruit, and the orchard house enabled him to grow and to fruit the trees in a space of time shorter than had ever been accomplished before, and with a security which induced him to proceed in the work, and this he certainly did with untiring energy.

At this period the Horticultural Society of London was not in a very flourishing condition; its efforts for the time seemed paralysed, and there was no authority to which a raiser of new fruits could submit his seedlings to ascertain their merits or to receive a commendation. In 1853 the idea of a Pomological Society was first suggested in the pages of this Journal. The need for such a thing was evident from the favour by which it was received, and accordingly on the 10th of July, 1854, the British Pomological Society was instituted at a meeting held at the house of the Horticultural Society in Regent Street, the chair being occupied by Mr. Rivers; and Mr. Spencer of Bowood and Dr. Robert Hogg being respectively Treasurer and Secretary, and the promoters of the movement. The impetus that was given to fruit culture by the establishment of this Society was very marked, and so useful had it become as a promoter of this branch of horticulture that the Horticultural Society of London a few years afterwards invited the members to amalgamate with that Society, and it ultimately became the Fruit Committee of the Royal Horticultural Society, which still continues to do the work which the original Society was instituted for.

It was at one of the meetings of the Pomological Society that Mr. Rivers exhibited his first seedling, obtained by crossing the old varieties of Nectarines with the Stanwick. He early discovered the faults of the Stanwick, and that it would never be a useful fruit for the outdoor climate of these kingdoms. Its

flavour he knew was exquisite, but its liability to crack, and requiring more heat to ripen it than can be obtained from a cool house or an open wall, were defects he endeavoured to obviate by crossing it with some of the hardier varieties. This he succeeded in doing, and accordingly on the 6th of August, 1857, he exhibited at the meeting of the British Pomological Society two seedling Nectarines from the Stanwick, being only seven years from the time when the plant was first distributed. One of these appeared for several years in his fruit catalogue as Stanwick Seedling No. 3. On the 5th of August, 1858, he exhibited for the first time a seedling Peach, which was subsequently named Rivers' Early York, by which this excellent Peach has now become widely known. On the 9th of September, 1858, he exhibited a seedling Nectarine raised from a Peach stone, and which is now so well known as Prince of Wales. In 1859 he raised Rivers' Orange Nectarine from Pitmaston Orange, and in 1861 were announced Pine Apple and Victoria Nectarines, and Early Albert and Early Victoria Peaches. The Nectarine Peach raised from the stone of a Nectarine appeared in 1862. In 1865 there was a strong addition to what would to many have appeared sufficient, and these were Peaches which have now established their reputation—Alexandra Noblesse, Dagmar, Dr. Hogg, Early Alfred, and Lord Palmerston. The year 1867 brought a measure of good fortune as compared with which all that had been done before sank into comparative insignificance. This was the raising of *Early Beatrice*, *Early Louise*, and *Early Rivers* Peaches. These by their wonderful earliness have added nearly a month to the duration of the season of Peaches. That grand Nectarine Lord Napier, which was raised from a stone of *Early Albert* Peach, first appeared in 1870. But space will not allow us to record all Mr. Rivers' achievements in fruit-raising; suffice it to say that in this way he has accomplished far more in the short space of time between 1854 and 1874 than can be attributed to any other worker in the same field, and with results that will be lasting.

Whatever tended to add to the pleasure of the people by extending the culture of fruits by modes that were simple and inexpensive, was sure to meet with Mr. Rivers' support. Cheap glass erections, whether they were mere shades over enclosures of Beech hedges, glazed wooden structures with roofing-felt for walls and heated by a brick Arnott stove which he himself contrived, or a sand-pit planted with Vines and covered with a simple glass roof—these were so many ways by which he showed practically that fruit culture was simple, inexpensive and remunerative, producing good returns with a large amount of pleasure. Another of these contrivances, though it did not originate with, was introduced and eagerly fostered by him. This was the ground vinery, which when carried out properly is one of the most valuable adjuncts to a large or small garden. As we have frequently seen it producing most handsome bunches of Black Hamburgh and other Grapes, we are confirmed in our opinion that it is a great boon to the owner of a small garden who either has no glass houses, or who may be afraid to build them as fixtures to a freehold which is not his own.

To recount all the labours of Mr. Rivers would fill a book. We will conclude by giving a list of the fruits that were raised by him as recently published in the pages of a contemporary.

Peaches.—Albatross, Alexandra Noblesse, Comet, Condor, Crimson Galande, Dagmar, Dr. Hogg, Early Albert, Early Alfred, Early Beatrice, Early Louise, Early Leopold, Early Rivers, Early Silver, Falcon, Gladstone, Golden Eagle, Goshawk, Lady Palmerston, Large Early Mignonne, Lord Palmerston, Magdala, Merlin, Nectarine, Osprey, Prince of Wales, Princess of Wales, Radclyffe, Rivers' Early York, Sea Eagle, Stanwick Early York.

Nectarines.—Advance, Albert, Albert Victor, Byron, Dante, Darwin, Downton Improved, Humboldt, Lord Napier, Pine Apple, Prince of Wales, Rivers' Elruge, Rivers' Orange, Rivers' White, Stanwick Elruge, Victoria.

Plums.—Autumn Compôte, Blue Prolific, Czar, Early Favourite, Early Rivers, Early Transparent Gage, Grand Duke, Late Rivers, Late Prolific, Rivers' Early Apricot, Rivers' Early Damson, Sultan.

Pears.—Beacon, Fertility, Princess, Seedling Bergamot, St. Swithen, Summer Beurré d'Arenberg.

Apricot.—New Large Early.

Cherry.—Early Rivers.

Raspberry.—Autumn Black.

Strawberries.—Royal Hautbois, Seedling Eliza.

And thus have ended the labours of one who did much to make life happy, and so add in no small degree to the in-

dustrial wealth of the country, by encouraging, like John Evelyn, the planting of fruit trees.

NOTES AND GLEANINGS.

We are informed by Mr. Killick that the APPLE ELECTION will appear in the next number of the Journal.

— THAT pretty and curious shrub *COLETTIA HORRIDA* is now in full bloom in the garden of Mr. Harrison Weir, where it is perfectly hardy, and flourishes without the least protection. The situation is an elevated one near Brenchley in Kent, and here many other plants stand out of doors that require protection in some parts of the country.

— We have rarely seen Mrs. PINCE'S MUSCAT GRAPE grown better than it is in a house entirely devoted to its culture by Mr. Harrison Weir of Weirleigh near Brenchley. The bunches are very large and well set, and the colour and bloom are perfect. Where Mr. Weir considers his success rests is that the house is lofty, the rafters long, so that the Vines have scope for producing an abundance of healthy foliage, and an abundance of air is constantly admitted, but always from the side away from the wind. This is managed by having a large space to open at each end of the house as well as on the roof, and air is never admitted except on the lee side.

— THE REV. W. F. RADCLIFFE states that *DÉSIRÉ CORNELIS* PEAR was raised by Van Mons, but it did not fruit till five years after his death. It is in shape like *Beurré Diel*, and of the flavour of *Marie Louise*. It ripens about the same time as Williams's *Bon Chrétien*—about the end of August.

— We learn from the *Dundee Advertiser* that the annual general meeting of the members of the DUNDEE HORTICULTURAL SOCIETY was held on the 26th ult., about 150 gentlemen being present. The Treasurer (Mr. James Hardie) read a statement showing the condition of the Society financially. He stated that the income from members' subscription, entrance money, &c., was above that of any ordinary previous year, while the ordinary expenses had been less. Owing to the liberality with which prize money had been distributed there was a deficit of £70 on the year's transactions, but they had still £414 13s. 9d. at their credit. In the year 1865 the Society only paid £58 as prizes, and since then it had gradually risen, and now stood at £342. Of the entire income of the Society since its commencement (£6518 18s. 6d.) there has been given in prizes £3300. The income of the past year, including balance, had been £1056 18s. 7d., and the expenditure £642 4s. 10d., showing a favourable balance of £414 13s. 9d. Previous to the election of office-bearer for the year Mr. Thyne moved—"That no partner or employé of any seed or nursery firm be eligible for election as an office-bearer," which, after discussion, was rejected by a large majority.

— THE CHRYSANTHEMUM SEASON is approaching, and good displays of this flower are anticipated in the metropolitan district. The plants at the Inner Temple never looked more promising than this year, and the collections at the Crystal Palace and Victoria Park are extensive and excellent. The collection at the Temple will be in beauty from the 1st of November, but some varieties are several days later this year than they were last. The Stoke Newington Society appears to be divided, for their exhibition is advertised to take place in two separate places—at Stoke Newington on the 16th inst. and at the Westminster Aquarium on the 20th. Brixton and Gravesend Shows open on the 14th, Walton on the 15th, Ealing on the 17th (it having been postponed from the 10th), and Kingston and Dartford on the 21st of the present month.

— "A WELSH READER" informs us that one of the most extensive FLOODS within memory has occurred this week in South Wales. Cardiff Castle, the seat of the Marquis of Bute (lately figured in the Journal), was nearly surrounded with water, and the grounds covered to the depth of 3 feet.

— AT their annual ROOT SHOW to be held at the Agricultural Hall, Islington, on November 14th and 15th, Messrs. James Carter & Co. offer good prizes for farm roots, also for vegetables and Potatoes. Messrs. Sutton & Sons, as usual, offer liberal prizes at their Root Show on November 24th, and they amount to nearly £500. Many manure manufacturers also offer prizes at the same Show.

— AN AMATEUR writes to us on the CULTIVATION OF HYACINTHS, that he last year received a collection of bulbs from Messrs. Veitch, some of which were so fine that he purchased

for them some extra large pots. In due time he had a very fine display, but—and this is the point to which he directs attention—he considers that he wasted his money in purchasing the large pots, for the spikes from bulbs grown in 48's (5-inch pots) were quite equal to those produced by 6 and 7-inch pots. He had excellent spikes from bulbs grown in 4-inch pots, which size is often very convenient for decorative purposes. With rich light soil and careful watering, using clear soft water as a stimulant when the spikes are advancing, satisfactory results, our correspondent remarks, may be produced in Hyacinth culture by employing pots considerably below the orthodox size.

— ALTHOUGH there was a good attendance at the CLEVELAND HOUSE plant sale (Mr. Ralli's) on Tuesday last the prices obtained for the plants were not large—some, indeed, being small. *Nepenthes Rafflesiana*, a splendid plant with nearly sixty pitchers, realised 23, and *N. lanata* 14 guineas. Seedling *Crotons* Madame Ralli and Leggi, raised by Mr. Legg, were sold for £12 and £4 respectively. *Anthurium Scherzerianum* Leggi was secured for 10 guineas, and *A. S. Album* (Bull's variety) with ten crowns for 15 guineas. The specimen *Crotons* only realised comparatively small amounts, the fine plant of *Volutum* being bought for 4½ guineas. A good plant of *Lapageria alba* was sold for £9, and a fine specimen of *Cycas revoluta* for 10 guineas. The *Heaths* realised from £1 10s. to £5 10s. The total amount of the sale was £392. The principal buyers were Messrs. Bull, Davis, Humphreys, Jackson, Lee, Shuttleworth, Wills, Walker, Warren, Williams, and Wheeler. Mr. Warren bought the exhibition van for 55 guineas.

— ONE of the best examples of successful FRUIT CULTURE which we have this year seen is at Barham Court, Maidstone, (Mr. Roger Leigh's). The crops appear to have been good, judging at least by the appearance of the fruit-room, which contains a noteworthy collection of well-grown and highly-coloured specimens. The trees are principally grown as espaliers, cordons, and pyramids, and their condition affords evidence of Mr. Haycock's skill and care.

— A VERY satisfactory instance of LAPAGERIA CULTURE has come under our notice in the garden of R. Hudson, Esq., Clapham Common. The *Lapageria* in question is growing in a large pot, and is trained near the roof along the south front of a large span-roofed plant house. In such a position the light is often too intense for this fine climber, and it would probably be so in this instance but for the shade afforded by a shelf which is placed along the front of the house; and under the shelf—not above it—the *Lapageria* grows luxuriantly and flowers profusely. Thus the space, the under side of a shelf, which is usually unoccupied, is here turned to account in a most satisfactory manner. The plant is kept scrupulously clean and has the best attention in watering. The opposite of those conditions—namely, drought at the roots, too much sun, and insect ravages, too often impair the health and mar the beauty of this beautiful greenhouse climber. Mr. Rapley the gardener, who grows other plants well, is to be complimented on so well pointing out a position where, with suitable care, the *Lapageria* will flourish in other greenhouses where space has not hitherto been found for it. Mr. Hudson only requires to have the white variety, which is one of the most chastely beautiful of all greenhouse flowers, to render the front fringe in his house complete. The same garden contains what would please the readers of the other end of this Journal—excellent arrangements for poultry and Pigeons, which are among the best that have come under our notice, and which are worthy of being again referred to. A little of everything, and that little done well, appears to be the guiding principle in the compact and enjoyable garden referred to.

THE KING'S ACRE NURSERIES, HEREFORD.

VISITING a Rose nursery when there are no Roses, or only a mass of decaying blooms which the early frosts of winter have despoiled, and when the leaves are withering on the branches or have been driven therefrom by the violence of the equinoctial gales, may not be a favourable period for appreciating the beauty of the national flower arranged *en masse*, but it is at least opportune for affording an idea of the magnitude of the trade in the most popular of garden flowers. It was at such a period that I found myself at King's Acre, the celebrated nursery of Messrs. Cranston & Co., who not only rank amongst the foremost of British rosarians, but who are

the donors of the greatest prize ever provided for competition at Rose tournaments.

The King's Acre Nurseries are situated about two miles from Hereford. The walk—or drive—is a pleasant one without being picturesque, and the observant traveller has not to proceed far before he perceives that he is in a district peculiarly favourable to Rose growth. Not only in the villa gardens skirting the town and in the cottage allotments "further afield" do Roses grow vigorously, but the Briars in the hedgerows tell us by their luxuriance that they enjoy a good larder and a congenial air. The atmosphere of Herefordshire is undefiled by the smoke of "works," such as foundries and factories, and the soil is such that renders the cattle sleek. It is under such conditions that Roses flourish—in such a district where Mr. Cranston has won renown by the excellence of his produce of blooms in summer and plants in winter.

In extent the nursery is about eighty acres; thirty of which are devoted to the increase and culture of Roses. Conifers, forest trees, and evergreens are largely grown, occupying about thirty acres, and there are twenty acres of fruit trees. Healthy and well-grown Conifers are attractive at any season, but especially during the winter, and the Conifer avenues at King's Acre are worthy a passing meed of commendation. They reach the entire length of the nursery, the shrubs, &c., in the borders being arranged with care—small and medium-sized specimens in choice variety. Alternating with these are avenues of Roses, which during the summer season must have an imposing effect. At the extreme end of the nursery is a boundary of specimen Conifers of commanding size and well-balanced proportions. The examples of these—Wellingtonias, Pinuses, Abies, Thujas, Cupressuses, &c.—are really excellent.

But it is the Roses, unattractive though they be, that primarily arrest attention. In no other place than in a Rose manufactory such as this can the extent of the Rose industry be appreciated. Thousands of Roses, even acres, are here seen. These are imposing—almost surprising; but more wonderful still is it to think that this is only one item in the great Rose trade of the country. We must think also of the Pauls, Turner, Cant, Veitch, Smith, Wood, and others who provide similarly powerful contingents, some of them perhaps even more powerful, to the national army of Roses in order to fully comprehend the full magnitude of the Rose trade in this country.

That Messrs. Cranston & Co.'s is an important Rose rendezvous must be admitted by all who inspect King's Acre, and especially, perhaps, if the visit occurs in the lifting and packing period. The quarters are then bloomless and almost leafless; but the character of the plants is better seen on that account—the sturdy bright wood, and, what is to the practised eye so attractive, the upturned bristling roots bushy and "close at home."

A striking feature of the nursery is a bed of 50,000 standards which have been budded during the present season. A path is arranged down the centre of this "plantation," to which the ground slopes; the Briars have also been assorted and planted systematically, the tallest at the extremities of the rows furthest from the eye graduating to the dwarfest at the ends next the central walk. During the blooming period next year these gigantic sloping banks of Roses will have a grand effect. This is only a portion of the stock of standards. The stock of Manettis budded during the present year is still larger and amounts to 200,000 plants. These are remarkably healthy, and have been budded very low. In order that the buds could be inserted quite close to the roots the soil had been dug out, and the budded Manettis are now in trenches. When growth commences in the spring the trenches will be filled-in and roots will issue from the bud, and thus aid the parent stock in furnishing support for the plants. But this is not all; for Roses thus worked seldom if ever produce suckers; and, moreover, Mr. Cranston places it beyond the power of planters to err in exposing any portion of the Manetti stock above ground—an important provision. The Manetti should always be covered to insure success, and with plants worked so low as these are it must be covered, for they simply cannot be planted without covering the junction of the bud and the stock.

The stock of Manettis now ready for distribution amounts to 150,000 plants. But many—some hundreds, probably thousands—have already been dispatched, as was evident by the large blanks in the quarters, and similarly by the loads of bundles and packages awaiting their turn for delivery. Roses were being packed not only for British gardens, but cases were being prepared for the Continent, especially Italy, for America, Ceylon, and even New Zealand and Australia. For

the long voyage of three months the plants are specially prepared. They are chiefly small plants of the newer varieties. The roots of each are firmly "mossed," and about 150 plants are placed in each case, and nearly all are found to reach their destination safely. The foreign trade in Roses is evidently a great one, and it is no slight compliment to English packers that are able to secure the safe transit of Roses even to the Antipodes.

For the packing of Roses to home districts fern (bracken) is employed at King's Acre instead of straw. It is found to be considerably cheaper than straw, while it is quite as good if not better for the Roses. Mr. Cranston purchases the bracken from Wales, and the extent of his consignment this year is suggestive: it amounts to forty tons of dry fern. This is stored as far as possible in barns, which are now full, but when the packing season is over will be empty.

A visit to a great Rose-growing establishment during the packing time affords an excellent opportunity for observing the varieties which are most popular with the Rose-growing public. And here the old Gloire de Dijon has a more honourable position than in the Rose election. Of all Roses it is the greatest in request. The stock of it—and a fine sight it is—at King's Acre now ready for distribution is upwards of six thousand plants, and these even on the 20th of October were "all sold!" The stock of Maréchal Niel is, to use a nursery phrase, always "run off its legs." Baronne de Rothschild is the most popular of the light Roses, indeed of any Rose excepting those above named, and upwards of five thousand are provided to meet the demand. La France sustains its popularity and increases in favour yearly. Four thousand plants have recently bloomed grandly at King's Acre, and another year they will bloom somewhere else. It is one of the most continuous in blooming of all Roses—one of the most chastely beautiful, and one of the most sweet. Amongst the dark Roses Alfred Colomb and Marie Baumann head the list in the public estimation, and the pair are here represented by nearly ten thousand plants. Of other varieties the Rose election poll of the *Journal of Horticulture* is a good index of merit in public estimation, and the Roses there honoured are increased accordingly.

Mr. Cranston's fine Rose Sir Garnet Wolseley is apparently in great demand, for the stock is large and the blanks already numerous. Another King's Acre Rose—a garden decorative and forcing Rose—Cranston's Crimson Bedder, is grown largely and sold readily; indeed the stock of this year is already "sold out." An order of five hundred plants of it for America was being executed. These were principally for forcing, it having proved valuable as a winter and spring bloomer.

Then there are the Teas—the lovely Teas. Year by year the demand increases for these charming Roses, and glass erections have to be increased for growing them in pots. Many hundreds of small plants are plunged in brick pits and protected when needful; and larger plants are accommodated in houses—splendid plants, it may justly be written, and splendid houses. One of them, a new one just erected by Messrs. Boulton & Paul, is an extremely fine structure; not highly embellished, but neat, light, strong, and well arranged and ventilated. The glass of this house (21-oz.) is well bedded in putty, but no top putty is used. It is a span-roof, 150 feet long by 24 feet wide. There is a central stage or bed, and side stages, with hot water beneath for bottom heat in the propagating season, when cases are placed over the beds which are now filled with fine plants. These plants were worked in January last, and are now in 7 and 8-inch pots—large plants, well trained and ripened, which will bloom freely all the winter. A finer example of Rose-culture is seldom seen than that afforded by this admirable collection of Teas. What plants can surpass such as these for decorative purposes and affording button-hole blooms and drawing-room flowers? None. What can equal them? Few. Near this is another house still larger; it is the same length, but wider and more lofty—the Rose conservatory. Here in a broad central bed the Roses are planted out. "Trees," real trees, some of them are which would gladden the eyes of "PARSON'S GARDENER," for he would require a ladder for cutting the blooms. On the side beds are Roses in pots, but a few are planted-out with a view of arching them over the path at intervals, which will add to the attractiveness of this house. A "tree" of Maréchal Niel in this structure must be a "sight" when in bloom. Its stem is of great size, but it will persist in swelling faster than the stock of its foster-parent the Briar on which it is worked, and this may shorten its days.

Other span-roofed houses there are of smaller size—about a dozen of them—some filled with Roses, some with Vines in pots, some with greenhouse plants, and some are propagating houses for Conifers, which, with fruit trees, appear to be next in importance to Roses in this nursery.

A large tree in the centre of the nursery demands notice—a fine old specimen of a weeping English Oak. It originated here; its branches are distinctly pendant, and it is very ornamental. On the lawn adjoining Mr. Cranston's house is a grand specimen of the Cedar of Lebanon planted about ninety years ago by a former proprietor; it is matched by a Purple Beech planted at the same time, but the Cedar has attained the greater proportions. The lawn is now cheerful by some admirable specimens of *Thuja aurea*, which show to advantage now the flower beds are bare—bare but not unsightly, for they are planted with bulbs, and neatly finished in a workmanlike manner, which contributes so much to the appearance of a garden in winter. The outside of the residence is draped with Ivy and Wistarias. And the inside? Well, it contains all that a wandering rosarian needs—quiet but genial converse, rest, &c.

Such is King's Acre in winter. What must it be in summer? Perhaps a "HEREFORDSHIRE INCUMBENT" will tell us by-and-by.—NOMAD.

SPIRAL VALLISNERIA (*V. SPIRALIS*).

NATIVE in ditches in Italy, especially near Pisa. Communicated from near Arles in Provence by the late Dr. Broussonet

Fig. 65.—*Vallisneria spiralis* mas.

in 1784. Mr. Brown found what he is almost certain of being the same species in New South Wales, about Port Jackson. This plant is perennial, flowering in summer and autumn. The root consists of long fibres, and propagates itself very widely by means of runners, so that the canals in which the *Vallisneria* grows are choked up with its foliage and rendered not navigable for boats. Stalks of the female flowers very long, thread-shaped, unbranched, single-flowered, curiously spiral, but becoming more or less straight when the flower is ready to open, by which means the latter floats on the surface, and after impregnation the stalk coils up again and lodges the fruit at the bottom of the water. This fruit is

3 or 4 inches long, and are rather of the nature of a berry than a capsule. The male flowers grow on a separate plant on short, simple, straight, radical stalks. Each minute white flower separates from the common spadix, and rises closed, like a little bubble, to the surface of the water. Bursting there, these flowers float about in immense numbers, covering the water, and impregnating the females above described.

Fig. 66.—*Vallisneria spiralis* femina.

This singular aquatic plant is popular in small globe aquariums; it grows with tolerable freedom and is not difficult to manage, and the great interest attaching to it when grown in this way is to see the circulation of the sap, which can easily be observed with the naked eye.

NOTES FROM CORNISH GARDENS.

PENTILLIE CASTLE, THE SEAT OF COLONEL CORYTON.

UPON a steep and thickly wooded hillside high up among the trees, standing out clearly, yet having an air of snug cosy warmth, is Pentillie—a stately building with elegant surroundings upon a commanding yet sheltered position in the centre of a wooded crescent, with the river Tamar flowing past its foot in a bold graceful curve, onward in serpentine sweeps to a still bolder curve, where it widens like the expanse of a lake, beyond which rise other hills undulating and broken—not into abrupt declivities or anything approaching startling contrast, but with rounded contours and flowing outlines, wonderfully varied yet all in harmony. That is the characteristic of the Castle and its position, of its pleasure grounds and woods, of the views which it commands; unity, fitness balance—no clashing, not one offensive object or feature; softness and repose most skillfully interwoven with infinite variety.

My work of inspection and note-taking at Pentillie were done quietly, deliberately, and under peculiar advantages; but too often one's visit to places worthy of careful inspection is just a mere rush through, a hasty scribbling of notes and away again to catch some inflexible "express." Here it was not so. In response to an invitation from its kindly owner I arrived at the Castle overnight just as darkness was coming on so fast as to impart a weird-like indistinctness to everything out of doors, even including a magnificent *Magnolia grandiflora*, to which I, and Mr. Boscawen, who accompanied me, groped our

way to have "just one look" before going in. In the morning the first sight which met my eyes was a *Pinus insignis* full 80 feet high in perfect health, and no unworthy rival of the Lamorran trees, standing right before my bedroom window upon a steep grassy slope running from the terrace bounding two sides of the Castle down to the bottom of a glen which intersects the crescent, not detracting from but rather contributing to the grace and beauty of the general effect, while forming in itself a distinct and striking feature. There are other fine trees near the insignis, over which I looked on to the farther side of the glen, all clothed with a dense growth of deciduous trees, and with just a few picturesque old Scotch Firs upon the highest point of the slope, imparting a finish and character to the scene so unique that with the sense of admiration came the more uncommon one of luxurious enjoyment. Such depths of shadow among the trees, such a play of

light among the branches, as the rays of the rising sun glinted down among them! It was one of those clear bright mornings which come to us as summer lingers upon the threshold of autumn, and which always seems to me a fitting type of the calm bright happiness that soothes the declining years of a well-spent life; and as I threw up my window to enjoy the fair scene fully, up from among the trees came an intermittent cooing of doves, breathing of security, contentment, and peace.

A closer inspection of the whole of the grounds and gardens strengthened the agreeable impression to which this first view gave rise. I found much to admire—ample variety, many fine and distinct features, with an unity of tone and connection in every part; abundance of fine timber, flourishing specimens of many Conifers, flowering shrubs well represented and presenting themselves in that pleasant guise always attendant upon tasteful arrangement combined with healthy growth; a

Fig. 67.—PENTILLIE CASTLE.

good collection of climbing plants, beds and borders well filled with flowers in great beauty, and in the kitchen garden an abundant supply of vegetables and fruit, successional crops all in capital order and condition, reflecting much credit upon Mr. Edwards the able gardener, who evidently has his charge thoroughly well in hand.

The terrace is, of course, the most important feature of the gardens close by the Castle. It starts from a level expanse on the carriage front, and is continued along the south and east sides of the building, overlooking most of the scenery to which I have alluded. The abrupt descent of the slopes from the south terrace renders its retaining wall a high one, which has been turned to account by clothing it with a collection of thriving climbing plants, including most familiar with the more uncommon kinds of Myrtle, Pomegranates, *Solanum jasminoides*, vigorous, healthy, and very ornamental; as was also a large *Mandevilla suaveolens* that has climbed right on to the top of the wall, hard by an almost equally vigorous example of the sweet-scented *Clematis flammula* bearing a cloud of its pretty flowers. *Magnolia grandiflora* was also well represented by several large specimens both here and upon the Castle itself, all of them remarkable for the large size of the deep green glossy foliage clothing every part of the sturdy branches. A ribbon border running along the foot of the terrace wall gay with summer flowers contained an uncommon and very attractive feature in a broad back row of

Lilium speciosum rubrum, or roseum, just bursting into flower, and which would thus serve to impart a freshness—a kind of autumnal beauty, to the border that is desirable and worthy of imitation.

From the east terrace a lawn slopes gently outwards to the crest of the hill which sweeps upwards to it from the river, all covered with timber and an undergrowth of *Rhododendrons*. The outward boundary of the lawn is a low belt of shrubs composed entirely of choice flowering kinds, imparting brightness and variety at all seasons of the year, and which in spring and early summer must form a gay floral fringe that is in charming contrast to the dense foliage of the tree tops below. This lawn imparts dignity to the adjacent buildings and an air of repose, but not quite in the telling manner it would do if its somewhat stiff formal semicircular outlines were softened into more graceful flowing curves, and three or four flower beds now dotted upon its centre were turfed over. It is true that these faults are quite of minor importance, yet where all else is so superior one does not like to see a single blemish; nor are these likely to remain unaltered, for a conservatory in course of construction close by betokens a spirit of progress and desire for improvement.

Retirement, seclusion, and pleasant shade abound in the numerous paths winding among the trees from the terrace along the slopes down to the river. As we go down flourishing examples of Oak, Chestnut, and Beech are seen on all sides,

forming a pleasant sight, and a useful lesson in the conviction which they bring to the mind of careful planting and judicious thinning, the free stout growth of the Oaks especially presenting a striking contrast to the stunted appearance of the Oak coppice, of which one sees so much in Cornwall. These trees are seedlings, while the coppice growth is all from the stools of old trees that have been cut down, hence the difference. At the river side a flight of steps leading down to the landing-pier impress one as being in good keeping with the position, consisting as they do of simple blocks of granite with no elaborate balustrades, but with what may be termed natural and certainly very ornamental spandrils of Escallonia, Berberis, Spiræas, Cotoneaster, Garrya, and Pampas Grass, all mingled together in wild and charming confusion.

The only really level expanse is by the carriage front of the Castle, not a formal court, but having its outline apparently determined by the natural formation of the adjoining slopes, falling away on one hand and rising on the other in picturesque variety. It forms a central point upon which the carriage drive and the walks leading to the most important features all converge. The idea is a happy one, and we will act upon it by making one or two excursions from here, turning first to a walk along the inner slope of the glen under the overhanging branches of some "brave old Oaks," past several flourishing Deodars and other choice Conifers, onwards for a considerable distance till it enters the wild woodlands beyond under an overhanging arch of leafage, forming an appropriate ending to the dressed grounds in that direction. The treatment of this inner slope is so excellent as to merit a full description, which shall be given in due course; and I will only state here that its frequent unbroken stretches of turf from the walk down to the bottom of the glen tend materially to enhance the effect of the densely wooded outer slopes.

Grand old plants of Yucca, Berberis, Arbutus, Rhus Cotinus, and Rhododendron stud the banks which rise abruptly on the other side of the carriage front. Upwards among them winds another path to a charming little flower garden—a circle with surrounding pillars and pendant chains, all covered with climbing plants, and with a novel entrance through an arcade of Cotoneaster microphylla. I am tempted to linger here, but must not, for the constantly ascending path leads onwards among rich masses of shrubs, and still invites us to explore. We follow, and are well rewarded, as we enter an American garden, which I must pronounce most excellent. Its outlines are a series of long irregular symmetrical curves, with a background of tall trees. The beds, also having irregular curved outlines, are on turf, and contain Rhododendrons, Azaleas, Kalmias, and Andromedas, all of large size and in robust health. The walk winds upwards among the beds, and it is when one reaches the upper end and turns to look back that the full beauty of this garden is seen. Nothing clashes, all is in harmony: the beds in their disposal, their form, and the shrubs which they contain. The enclosing belts of shrubs and trees exclude all surrounding objects except just one little opening at the lower end, where through a fringe of boughs a narrow vista of the river, the swelling country beyond, and the granite crags of a lofty tor on distant Dartmoor, meets the eye like a vision of fairy land, the reality being far more beautiful than any fanciful conception ever could be. It is true that the garden itself is a work of art, but this glimpse of rich natural scenery, lying far away beyond its boundaries, and yet apparently so near, imparts a charm and finish to it of which mere description can only serve to convey a faint idea.

From the Rhododendron garden the walk goes onwards among other shrubs, still ascending under lofty trees, many of which have Honeysuckles trained up the stems and left to ramble wildly among the branches—till it leads out into the grassy uplands of the park, where from the highest point the whole magnificent landscape comes fully into view, spread out before the eye—a veritable panorama. Nothing appears to be wanting; water, woods, hills and valleys, breezy uplands and shadowy hollows—all are here in infinite variety, stretching away far as the eye can reach in rich and picturesque profusion. In the foreground the winding Tamar stands out prominently, and away to the south-east, over the waters of the Hamoaze, are the clustering houses of Devonport and Plymouth; the Albert Viaduct at Saltash, Brunel's greatest work; the heights of Mount Edgecombe, whence the eye sweeps westwards over many other places "famed in ancient story," but which I must not enumerate here, catching glimpses as it passes of lofty hills which loom dimly in the far distance, and

numerous tors that spring upwards from the bosom of rugged Dartmoor.

I must not conclude these notes without devoting a few words to the kitchen garden. The path from the Castle to this garden is a straight one 9 feet wide and 400 feet long, the branches of large timber trees overhang it, and it has a broad fringe of Fern on each side, so that it has a cool, shaded, refreshing appearance that is very inviting in summer. In the garden I found some good black Grapes well coloured; excellent Muscats—not exactly prizewinners, but with plenty of those well-finished, compact, little bunches that tell best upon the dinner-table. Peaches were abundant and the trees in capital condition, both on open walls and under glass. Cherries and Figs are grown in curious structures formed of a framework of timber with fine wire netting stretched over it—a novel and sure way of excluding birds, but not a desirable object to see permanently established in a garden.

There were some good plants in the houses and a capital lot of Gardenias in a pit, with the pots plunged in leaves, which impart that cool moisture in which this plant thrives best in summer. A bed of Solanum Capsicastrum in an open border was excellent, as the plants invariably are when so treated in summer, the branches being laden with berries and well clothed with deep green foliage. The treatment of these and other plants in course of preparation for the coming winter, together with the excellent condition of the vegetable crops, all betokened intelligent culture and painstaking alike worthy of the garden and creditable to the gardener.—EDWARD LUCKHURST.

PEARS.

In answer to "L's" letter on page 305 I beg to say we can supply him with trees of the Pear he requires, Désiré Cornelis, as dwarfs or pyramids on the Quince stock. With us it is a Pear possessing good flavour and is of medium size.

I am very much surprised to hear that Louise Bonne de Jersey does not succeed well with him, as with us it bears well in the orchards as a standard, attaining a fair size, and is first-rate in quality. Beurré Bosc, another Pear he mentions as variable, has with us proved to be one of the best orchard Pears. Some years ago we grafted an old tree of Aston Town or Grey Beurré standing in the orchard with this variety, and it has borne large crops of fruit I believe every year since. This season is in our neighbourhood a most wretched one for nearly every kind of fruit; notwithstanding this our friend Beurré Bosc has borne a crop of 8 pecks, 18 lbs. to the peck, and the quality was sufficiently good to command a price of 6d. per pound. "L." does not mention Williams' Bon Chrétien. I should think it would succeed well with him. With us it is very hardy, and bears almost every year; this year, however, it had but a poor crop. Beurré d'Amanlis is another hardy Pear, which as a rule bears large crops as a standard, but this year it has failed us. This is scarcely to be wondered at, as on March 1st we enjoyed three hours' skating, the thermometer having registered 16° and 18° of frost the two previous nights. Pears which had set a fair crop and were looking well lost all their fruit. I can fully endorse all that your correspondent Mr. Witherspoon says respecting Marie Louise d'Uccle. It is extremely hardy, and of first-rate quality for an orchard Pear. Each season we have an increasing sale for this Pear.—ALFRED H. PEARSON, *Chilwell, Notts.*

GLOIRE DE DIJON ROSE.

It is somewhat remarkable that this, the most popular and best known probably of all Roses, should not rank high as an exhibition Rose, but it is none the less true; and rarely where the class is limited do we see an exhibitor venturing to place it with his Marie Baumanns, Alfred Colombes, &c.; it lacks the form and permanency so desirable in an exhibition Rose. But wherever a few Roses are grown, there in some form or other, as a standard, but more frequently as a climbing Rose, is old Gloire to be found. A detailed history of it is given in the "Journal des Roses" for October, but, as has been remarked, nothing is said of its parentage. There is a very good reason for this—nothing is known of it. Some years ago I had the pleasure of visiting the gardens of M. Henri Jacotot at Dijon, where it was raised, and he told me that it was entirely a chance seedling, coming up in an out-of-the-way corner of his garden, but from whence he knew not. It would indeed be a curious thing to know of how many of our best Roses can the pedigree be traced, and whether hybridising is much resorted

to among rosarians (I do not speak of English raisers, but of foreigners). I remember some years ago the elder Margottin of Bourg-la-Reine saying to me that he thought we were getting too much of the blood of G  r  al Jacqueminot amongst our Roses, and that he was going to try back, at the same time showing to me the plants from which he was hoping to obtain seed; but he has obtained nothing since that year of any value. We read indeed of such a Rose that it is the "issu de Jules Margottin," or "Victor Verdier," &c., but I think that simply means that the heps have been gathered from these varieties, not that they have been hybridised; my own impression (it may be a wrong one) being that this is not in any appreciable degree resorted to by our neighbours. There is one thing in connection with this Rose that I would notice, and that is the miserable caricature of it that appears in the "Journal des Roses." I remember when I edited the "Floral Magazine" how often I used to be bantered about Andrews' figures of Roses, and how often the superiority of the foreign artists was lauded. Well, take this plate for an example, and can anything be more wretched? Neither in form, colour, or foliage is it a bit like the Rose, and I am sure that neither Fitch, Worthington Smith, Burbidge, or McFarlane would venture to turn out such a production. Whatever they may do in other matters, we certainly cannot say of the figuring of Roses "they do these things better in France."—D., Deal.

ADIANTUM FARLEYENSE.

It is a gem amongst Ferns, and by this time has found its way into almost every collection; and when for the first time a plant is procured we justly regard it as a treasure that requires our tenderest care to develop it into all its natural grace and beauty. It is truly the queen of its genus, and those distinct qualities which it possesses render a special note on its successful culture desirable.

The plant is certainly of easy growth, for in the hands of nearly all Fern-growers no difficulty is experienced in producing fine healthy fronds. But still it is a fact that many cannot succeed with it; in this case undoubtedly the disappointment of the gardener is equal to that of the employer. Sometimes I have found it in a cold fernery, sometimes in a greenhouse, and planted out as a rockery plant; it is seldom to be found in perfection in such situations as those. It is extremely tender and delicate when sent out by the trade, and a check is often given in transit which is not soon remedied. It delights in a shady quiet atmosphere—no sun, no draughts, and a close barrier between the plants and hot pipes. I find it is a good plan to have the stage slated over and covered with a layer of gravel, or cocoa-nut fibre refuse, which I give the preference to. Afterwards I place the plants on inverted pots; this brings the plants 12 inches higher than the ordinary level of the stage plants, and affords ample room for the Ferns, and enables their graceful weeping to be admired from all sides.

In paying a neighbourly visit to some of my friends I invariably find this Fern potted in a compost which is anything but suited to its requirements. On one occasion I discovered it potted in bog peat and silver sand. On such discoveries I invariably recommend the *Journal of Horticulture* as a remedy for such vexing mistakes. The standard compost for this Fern is usually peat, loam, and charcoal in equal parts. It should be thoroughly mixed, open, and rough. In this they will grow vigorously. Care should be taken in the drainage; if defective the pots become waterlogged. In potting I have found it a good practice to keep the stool of the plant rather high, as the fronds come more vigorous. When the pots become filled with roots I find liberal watering requisite, still given by one, however, who knows from experience when to withhold and when to give.

P.S.—Have any of your correspondents noticed A. farleyense to produce seed spores? I have carefully watched it, but so far in vain.—JOHN BOND, Balbriggan.

SILVER BEET.

This Beet is not so much grown as it should be. It is a very excellent vegetable. We have been using it since June, and shall continue using it for some time longer yet. Three long rows of it were sown with the other Beets at the end of April. The plants were thinned out to fully a foot apart, as it produces a bushy head of green leaves, each of which have a very large broad midrib pure white in colour. This is the part that is used. It is cooked precisely the same as Seakale,

and many tasting it for the first time take it for this vegetable; but it is much better than Seakale, and it is much longer in season, and also requires less attention in cultivation.—A KITCHEN GARDENER.

A ROSELESS AUTUMN.

I VENTURE to write a line to say how the Roses have done this autumn in the eastern counties. I am surprised to see in your *Journal* of October 18th in a letter by Mr. J. W. Moorman that Messrs. Fish and W. Paul have found this such a Roseless autumn. I am glad to say that this has not been the case by any means here. I quite agree with Mr. Moorman with regard to the autumn Roses this year. I never had such blooms before of such size, such substance, so abundant, or of so good a colour, that it was impossible to mistake what a Rose really was, as is so often the case with autumn blooms.

I will mention a few of the varieties which have done very well. I will begin with the Teas, which I may say have all bloomed abundantly, but especially Marie Van Houtte, Madame Camille, Catherine Mermet, Niphetos, Souvenir d'Elise, and the beautiful though much despised, at least by some, Cheshunt Hybrid. Of the Hybrid Perpetuals, Marie Baumann, Marquise de Castellane, E. Y. Teas (which I think will soon vie with Marie Baumann for first place in the Rose election), Madame Victor Verdier, Capitaine Christy, La France, Auguste Rigotard, Dr. Andry, Comtesse d'Oxford, Jules Margottin, and Comtesse de Serenye have been most conspicuous; but I could name several more, which would make this letter too long, but I must not omit the Baroness, which has been splendid—much better here this autumn than in the summer, when she was thin.

My soil is a stiff heavy loam, and, of course, good for Rose culture; but I attribute the beautiful blooms I have had not so much on account of the soil, but because a great portion of my Roses are budded on the seedling Briar, which I have obtained of Mr. Prince, Oxford. I am quite certain that the seedling Briar is the stock on which to grow the Rose, and I most strongly recommend those who grow Roses for exhibition to give the seedling Briar a trial, and I feel certain they will not be disappointed. I have to-day (October 19th), cut a large basket of Roses, and hope to continue to do so for a short time longer, until Jack Frost comes to rob us of our queen of flowers.—EDWARD LYON FELLOWES, Wimpole Rectory, Royston.

FORCING ASPARAGUS.

LAST spring in cutting the Asparagus we left one long bed untouched. This produced many strong shoots, which must have strengthened the roots very much. These stems are yellow and ripe now, and will be cut off close to the surface of the bed at once. In the first week in November a quantity of the roots will be lifted out of this bed for forcing, and the first dish will be cut from them about the middle of December. Asparagus is a favourite dish with our family at all times, but it is doubly valued at Christmas and about that time when choice second-course vegetables are scarce.

Asparagus is not a difficult vegetable to force. It cannot be forced, however, without a good deal of bottom heat. This is what is most required, and must be had either from hot dung or hot pipes. We force ours above both. A steady bottom heat of 75° brings it on well. Hot-water pipes in beds are generally covered over with boards or some other covering to prevent the stuff in the bed from resting on the pipes; over the platform of boards 2 inches of very open soil should be spread, then lift the roots, remove most of the soil from them, and pack them in the bed on the 2 inches of soil as close as they will lie together without covering one another. When the desired quantity is packed-in cover the crowns over to the depth of 2 inches with the same kind of soil as that which is below them, work it well in amongst the roots, and when this has been done give the whole a thorough watering with water heated to 80°. Keep the atmosphere close after this, but provided the bottom heat be 75° the air heat need not exceed 50° or 55°, and this need not be increased. The roots must be kept regularly moist. As soon as the young tops can be seen keep the atmosphere moist, and on sunny days the bed may be damped over with the syringe. Begin cutting as soon as the shoots are 3 inches high; cut off all the small twigs as soon as they appear. When the whole has been cut lift the roots out and throw them away. They will not pay to keep. About three weeks after the first lot has been

placed in heat another batch must be put in in the same way to keep up a succession. Where a supply is wanted until it is ready out of doors a lot must be introduced every three weeks until the end of February.

In forcing it on dung beds (the beds must be made up like any ordinary hotbed, with a frame on the top of it) spread the soil over the dung the same as it was over the pipes, pack the roots in, and do it exactly in the same way as in the pit; but care must be taken not to give too much water at the roots, as the soil does not become dry so quickly above the damp dung as the hot pipes. During cold nights, when the tops are above the soil, cover them with glass; when the heat declines add fresh linings around the frame. My greatest objection to hotbeds is that in wet weather they soon lose the heat, and this of course they are much more liable to do in winter than at any other time. I have a bed about 4 feet wide and the same in depth in the inside of a lean-to house which I fill with dung as a hotbed, and this I find holds the heat as long again as the hotbeds outside.—A KITCHEN GARDENER.

Johnston's Elements of Agricultural Chemistry. Edited by DR. CAMERON. Tenth Edition.

The above title is a guarantee of excellence, for both author and editor are well known as good authorities. One extract will show the nature and value of the contents.

CHANGES WHICH FARM MANURE UNDERGOES IN STORAGE.—Fresh farmyard manure generally contains about 70 per cent. of water and 30 per cent. of (dry) organic and earthy matters. Only a very small proportion of the dry matters consists of substances soluble in water. In a short time, however, the organic matters—straw, &c.—begin to ferment, one result of which process is the production of soluble compounds. Fresh manure produces but little effect when applied to crops; but when it is far advanced in decomposition (*i.e.*, well rotted), it then contains so much soluble matter absorbable by plants that it acts as a powerful fertiliser if used in sufficient quantity.

In fresh manure the most important constituent of its soluble portion is potash; of phosphoric acid and ammonia it contains but very small proportions. Rotten manure, on the contrary, yields to the solvent action of water large amounts of nitrogen and phosphoric acid. If good fresh farmyard manure be dried at 212° F., the soluble organic matters of the residue will be found to amount to from 7 to 8 per cent., and its soluble mineral matters to from 4 to 5 per cent. On the other hand, dry rotten farmyard manure contains from 13 to 16 per cent. of soluble organic matters, and 5 to 6 per cent. of soluble mineral substances.

Dr. Voelcker has shown that there is very little free ammonia in either fresh or old farmyard manure, and that the peculiar odour of the latter is not due, as popularly supposed, to the escape of ammonia from the manure. In the hot centre of a fermenting dung-heap some free ammonia is formed, but this is prevented from escaping by the cold outer layers of the manure, which act like a chemical filter.

Dr. Voelcker, in a paper of great value published in the 17th volume of the Royal Agricultural Society, gives the following summary of the changes which farmyard manure undergoes in storage:—

1. That during the fermentation of dung the proportion of both soluble organic and soluble mineral matters rapidly increases.
2. That peculiar organic acids not existing—at least, not in considerable quantities—are generated during the ripening of dung from the litter and other non-nitrogenised organic constituents of manure.
3. That these acids (humic, ulmic, and similar acids) form, with potash, soda, and ammonia, dark-coloured very soluble compounds. Hence the dark colour of the drainings of dung-heaps.
4. That ammonia is produced from the nitrogenous constituents of dung, and that this ammonia is fixed for the greater part by the humus substances produced at the same time.
5. That a portion of the sulphur and phosphorus of the excrementitious matters of dung is dissipated in the form of sulphureted and phosphoreted* hydrogen.
6. That volatile ammoniacal compounds, apparently in inconsiderable quantities, escape into the air.
7. That the proportion of organic substances in fresh dung rapidly decreases during the fermentation of dung, whilst the mineral substances increase in a corresponding degree.
8. That this loss of organic substances is accounted for by the formation of carbonic acid, oxide of carbon, and light carburated hydrogen, or marsh gas.

* It is not probable that phosphoreted hydrogen is given off during the decay of any kind of ordinary organic matter. Ploss and Hoppe-Seyler found that decomposing fish emitted sulphureted hydrogen, but not phosphoreted hydrogen.—C. A. C.

9. That the proportion of nitrogen is larger in rotten than in fresh dung.

LOSS OF FERTILISING MATTERS FROM MANURE.—The experiments of Voelcker show that farmyard manure does not lose much by exposure to air, heat, and light. The deterioration which ill-kept manure-heaps undergo is therefore due to losses by drainage. The dark-coloured liquid which we too often observe trickling away from badly kept dung-heaps is rich in nitrogen, phosphoric acid, and potash.

Koerte found that one hundred loads of dung kept in the usual wasteful manner were reduced at the end of—

	Loads.	Loads.
81 days to 78.8,	sustaining a loss of 28.7	
285 "	64.4, "	35.6
384 "	62.5, "	37.5
499 "	47.2, "	52.8

Thus in sixteen months more than one half—and that the most valuable portion—of the manure had disappeared, leaving a highly carbonaceous matter, poor in all the elements of fertility.

NOTES ON VILLA AND SUBURBAN GARDENING.

In a former calendar the lifting and transplanting of trees and shrubs was referred to, but the unusual spell of dry weather which has followed since those instructions were given has prevented most of us from fully carrying them out. Now that the soil has had the benefit of heavy rains we urge on all who contemplate alterations and additions of any kind to proceed with them as rapidly as possible. Whether it be the removing or thinning of already existing plantations, the renewing of fresh Rose beds, or the alterations or additions of fruit trees, the sooner they are permanently placed in their new stations the better chance they have of making fresh roots before the extreme cold weather is with us. A list of trees, shrubs, and climbers is appended. The selection is chosen either from their beauty or from some other good quality rendering them well adapted for small gardens. Many are excluded that are likely to grow out of proportion to the size of most villa or suburban gardens. Among the evergreen shrubs the *Aucuba* is especially noted for its spotted Laurel-like foliage, and its readiness to grow in almost any soil and situation places it pre-eminent as a town shrub. *Aucuba japonica* vera, maculata and angustifolia, are amongst the best. If the true green male variety is introduced the possibility is that during the winter months some of the shrubs will be loaded with beautiful scarlet berries. *Berberis aquifolia* and *B. Darwinii*, the many varieties of *Box*, *Cotoneasters*, *Escallonias*, and *Euconymuses* are also suitable; *Garrya elliptica* with its nut-like catkins is very attractive during mild winters; the various sorts of *Holly*—the Gold, Silver, Prickly, or Smooth-leaved—are very bright and always pleasing; *Olearia Haastii*, *Skimmia japonica*, *Veronica Andersoni*, *Yucca recurva* gloriosa and filamentosa, are all worthy of notice. Of deciduous trees and shrubs some of the Maples, such as *Negundo fraxinifolium* and its variety *albo-variegatum*; *Acer japonicum* polymorphum, *A. platanoides* dissectum and laciniatum; the Snowy *Mespilus*, one or two smaller-growing forms of the Birch, double-flowering *Cherries*, *Chimonanthus fragrans* and *Jasminum nudiflorum* for covering walls; Hawthorns, notably *Paul's New Scarlet*; *Cydonia japonica*; *Deutzias* crenata flore-pleno, gracilis, and scabra; *Leycesteria formosa*; *Syringas*, especially the large-flowering variety *Philadelphus grandiflorus*; *Prunus sinensis* flore-pleno; Elders of the variegated and cut-leaved varieties, and all the *Weigelas* are excellent for shrubberies. Of climbers *Ampelopsis hederacea* and *A. Veitchii*, *Clematis flammula* and *Jackmanii*, the various forms of *Ivy*, *Lonicera aurea reticulata*, *Jasmines*, and *Ceanothus Veitchianus*, *azureus*, *rigidus*, and *dentatus* are all useful for covering walls and fences. Compact specimens of *Conifers* for lawns are the Gold and Silver *Yews*, *Retinospora plumosa* and *R. p. aurea*, *Retinospora filicoides* and *R. obtusa* aurea, *Cupressus Lawsoniana gracilis*, and *C. L. erectis viridis*, *Thujaopsis borealis variegata*, *Thuja aurea* and elegantissima, with *Junipers*, are all suitable. For larger-growing specimens *Cedrus Deodara*, *C. Libani*, *C. atlantica*, *Abies Albertiana*, *Piceas lasiocarpa*, *nobilis*, *Nordmanniana*, and *Pinsapo*, *Thuja gigantea*, and the renowned *Wellingtonia gigantea* should all be included. Great care should be taken in planting those larger-growing trees not to place them too near to walks or the sides of buildings; for although at the time of planting they may look well, in the course of a few years they become obstructives, and then there is a difficulty of removing them.

In planting the various specimens care must be taken to break the ground well around and underneath them, and if large breadths of planting are done there is no better way than trenching the ground. Merely digging small holes and cramming the roots into them is like digging a grave to receive them, especially in heavy soil, for on such ground the water is held around the roots as if in a pond the whole of the winter, consequently the smaller fibres—the feeders—decay.

Selections of Roses have so recently been given in your pages,

and amateurs cannot do better than choose from the "election," for generally speaking the best exhibition sorts are also the best for general purposes. A deep pulverised and richly manured soil suits them best; and if there are any doubts that beds have become exhausted through being planted for a length of time, or that Elm or other roots of trees are exhausting the soil, by all means lift the Roses, deeply trench and manure the bed, and replant them again. Collect Briar stocks and plant them in rows for next year's budding. Roses in pots which have been plunged out of doors during the summer ought now to be placed under cover, merely keeping on the lights during heavy rains and in severe frost. The weather has been very favourable for ripening their wood, and an over-abundance of moisture must necessarily be kept from them, or the sap will rise and bleeding will follow pruning. Where pits or houses cannot be spared to protect them lay the pots on their sides and protect them from being frozen. Where early blooms are desired the plants should be pruned at once, and brought on in a very steady temperature. No flower has a greater dislike to harsh treatment than Roses in pots, and for very early forcing it is well to prune hard and use the smaller plants; the larger plants will make a greater display during the early summer months.

Chrysanthemums which have been recently housed must not be kept close, but air must be freely admitted if good foliage is desired. Continue helping them with manure water, as the majority of the blooms are very late this year. Elaine and James Salter of the Japanese section are the only flowers open with us yet. For some years we have had numbers of blooms open by the 1st of November.

Asparagus beds should now be cleared of their ripe stems and the weeds hoed off, and a liberal dressing of manure spread over the beds to lay throughout the winter. The principal other work for the present will be the collecting of leaves and keeping the garden as neat as possible.—J. W. MOORMAN.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

HARDY FRUIT GARDEN.

We have now had a good soaking of rain, which will enable us to do any transplanting that may be required. Previous sharp frosts have caused the leaves to drop. It is as well to take an early opportunity to transplant any trees that it is intended to move to another site, either because alterations in the winter require it, or young trees have grown too much and require to be removed to make room for others. When they have been for many years in one place the roots within 3 or 4 feet from the main stem are not well furnished with fibres. In order to insure complete success it is well to dig a deep trench round the tree and cut most of these roots at that distance from the stem, in the same way as we have already recommended for root-pruning; this should be done so as to allow a season to intervene between the time of cutting the roots and lifting the trees. After the growth of one season a mass or bunch of fibrous roots will have been formed from each root that has been cut, and when the tree is carefully lifted and planted in its new position it will suffer but little from the removal. When the trees are removed the holes, which of course must be ready for their reception, should be rather larger than the full spread of the roots. It is not always possible to have turfy loam decayed and chopped up to place amongst the roots, but if it can be had it tends much towards the formation of fibrous roots. When the tree is planted and the earth firmly levelled round it a mulching of manure must be placed over the roots, and it should extend to their furthest extent.

Owing to the rain we have not quite finished gathering all the fruit, but will do so the very first favourable opportunity. We frequently look over the Apples and Pears stored in the fruit-room to remove those that are decaying, as there is most injury from decay the first few weeks after the fruit has been gathered. We shall take the first opportunity when the ground is hard with frost to mulch under the dwarf-trained trees in the kitchen-garden borders with good manure. Many persons never dig under the trees, but we think it better just to lightly fork over the ground once a year—that is, in the early spring. It might be better for the trees to leave the mulching as it is, but we have found that it causes the kitchen garden to be very untidy at a time when every part of it ought to look its best. The small birds scratch the manure over the gravel walks, and if this is cleaned up one day it is scattered over again the next. Leaves are now blowing about in all directions, but as they are mostly down on the ground now we shall at least clear the walks of them.

PINE HOUSES.

We do not grow a sufficient number of plants that will fruit in the winter to devote a whole compartment to their culture. If we could do this the night temperature would range from 65° to 70°, according to the weather. The plants require to be

very carefully attended to as regards watering. It is better rather to under than over-water them. We examine the soil once a-week and water all that require it. As a rule the pots require water about once in two weeks. In fine weather the temperature by day may rise to 75° or 80°. No moisture is allowed to evaporate from the troughs over the hot-water pipes after the last week in October, and it is sufficient to moisten the walls and paths of the house twice daily. In our house, where plants are at rest to start early in the year, there are several fruits in various stages, some taking the second swelling and others just set. The temperature ranges from 55° to 60°, and with that temperature very little atmospheric moisture is required, and as the pipes are not much heated it is not necessary to sprinkle water about except after cold nights followed by sunny days. We are not watering the plants at all that are resting, and they are not excited by much bottom heat. Those showing fruit require water sufficient to keep the fruits plump and in a growing condition, as it is out of the course of nature to rest plants swelling their fruit, and we would have them in a higher temperature if we could. Suckers for succession are also wintered in the same temperature and receive very similar treatment. They are now growing in 6 and 7-inch pots, and will receive but little attention until they are potted into their fruiting pots in the spring.

ORCHARD HOUSE.

This structure is now filled with Chrysanthemums of the different types, either for specimens or plants trained to a single stem, so as to have flowers of the largest possible size. The fruit trees have as usual been plunged out of doors in cocoa-nut fibre refuse, where they will remain fully exposed to the weather until they are removed into the house about the beginning of the new year. Strawberry plants are also left out until about the same time. If the roots are likely to be saturated with water we lay the pots on their sides, which prevents injury from this cause. Should severe frosts occur it would then be quite necessary to place them inside, where the pots would be protected. We do not think the roots receive much injury from frosts, but the expansion of wet soil splits the pots.

GREENHOUSE AND CONSERVATORY.

This is a critical period of the year for Cape and New Holland plants. They are not unlikely to be attacked at this season by many of the ills that plant life is heir to. Mildew is, perhaps, the most insidious in its attacks. The leaves and branches are sometimes covered with its hair-like threads before it is perceived. The skilful and experienced cultivator is not to be caught napping, and he knows the plants most likely to suffer; knowing also that prevention is better than cure, his plants will be dusted with flowers of sulphur, which will resist any encroachments of the enemy. Next to it is red spider, which attacks many species and varieties. It has a warm affection for the pretty new *Boronia elatior* and others of this species besides, and as the under sides of the leaves are attacked first we lay the plants on their sides and syringe that portion of them thoroughly with tepid water. We shall now find an opportunity to train some of the hardwooded specimens into the required shape, and in doing this the habits of the plants ought to be studied. It is the nature of many plants to form irregularly shaped bushes, and when these are grown in pots a few of the stronger main branches will take the lead and overpower those of weaker growth; judicious pinching performed at the right time will prevent this. Sometimes it is better to tie such strong growths down, the weaker growths will then be encouraged. Many species need no sticks, others must have sticks placed to them to support the stems and form a regular shapely specimen. In this category come the slender-stemmed *Heaths*, *Dracophyllum gracile*, the several species of *Aphelexis*, &c. We use sticks made of sound pine wood painted green, and the most lasting material for tying is the black linen thread used for sewing carpets; it can be obtained at any carpet warehouse at a cheap rate. One shilling invested will serve the requirements of a large establishment for twelve months.

We have now potted the Hyacinths, Tulips, and Polyanthus Narcissus for late flowering. They begin starting into growth about the end of October, and we fancy it must exhaust the bulbs to allow them to do this. The potting material has been previously described, and we would now only say that the pots should be clean and be removed to an open space and covered with ashes, cocoa-nut fibre refuse, or some similar protecting material.

Some persons fancy that Hyacinths must be protected from heavy rains, and we have seen them stored under the stage of a greenhouse, than which there could scarcely be a worse position. We saw one lot much injured from this cause. When the pots were taken out some of them were saturated with wet from being under the drip of water from some of the plants; others had not been under the drip, and these were dusty dry. As a consequence of this mismanagement all the plants were weakly and did not flower well. We never saw them suffer from wet when the pots were plunged in the open.

The Lilliums were cut down some time ago and ought to be

potted at once. We shall have them done the first opportunity. They have sometimes been potted with turfy peat in the compost, and at others without it, using only turfy loam, and we did not notice any difference in the quality or strength of the flowers or spikes. There are some sorts of loam that do not mix well with peat; the loam of our own district does not. The best loam to mix with turfy peat soil is a yellow medium clayey loam, which is found at Wanstead, Wimbledon, and Epsom commons, and in which the common hardy Heaths grow naturally. We have not used any artificial heat in our houses this season yet, nor do we notice any injury from damp to the flowers.

FLORIST FLOWERS.

The Auriculas which have been all the summer and autumn behind a north wall have now been removed from that position to one where they are fully exposed to the sun. Previous impressions are confirmed, that the Auricula delights in a dull moist season. The northern growers state that they have seldom had a stronger or more healthy growth, and the weather there has been dull and cold enough with more than the usual quantity of rain. The weather with us has not been so favourable, and there is plenty of autumn bloom owing to the drought and heat when they were making their autumn growth.

Weather which has been favourable to the growth of Auriculas does not suit the Carnation and Picotee, and the principal growers in the north state that they have not yet been able to take off all their layers. The "grass" was not ready to layer until the last week in August, and the weather since has not been favourable to the development of the plants. Our own have all been taken off, and some of those left until the last (about two score pairs) did not seem to have any roots, or they were in some cases just forming; these were taken off and potted in the usual way, and the pots plunged in a gentle hotbed. In that way they speedily strike roots, and as the heat declines air is admitted more abundantly to strengthen the plants. Pinks certainly never made better growth than they have done this autumn—they are almost as strong as Picotees. The ground must now be stirred amongst the plants with a Dutch hoe.

We are about planting out a bed of seedling Pansies, and also named sorts. These plants are apt to become infested with green fly under glass, and it is convenient to put them out in their flowering beds at once.—J. DOUGLAS.

TRADE CATALOGUES RECEIVED.

Richard Smith, St. John's Nurseries, Worcester.—*Catalogues of Fruit and Forest Trees, Conifers, Roses, Alpine and Herbaceous Plants.*

Francis & Arthur Dickson & Sons, "Upton" Nurseries, Chester.—*Catalogue of Select Roses.*

James Bromwich, 25, Buckingham Palace Road, Belgravia, S.W.—*Catalogue of Dutch Bulbs and Room and Garden Ornaments.*

Cranston & Co., King'sacre Nurseries, Hereford.—*Descriptive Catalogue of Selected Roses.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

BACK NUMBER (*A Subscriber*).—You can have the number dated October 4th. ASHES AS MANURE (*J. F. K.*).—The sulphur will be beneficial.

GOLDEN QUEEN GRAPE.—We think it has been discussed sufficiently. Attention has been aroused, and cultivators may judge for themselves.

VALUATION (*A Constant Reader*).—Consult a neighbouring gardener. No one can give a trustworthy opinion without seeing the plants and knowing the locality.

JERUSALEM ARTICHOKE (*N. J. M.*).—If taken up before required for use place them in layers alternated with sand in a cool shed. If your garden nets are soaked in a tanner's vat and kept in a dry place the moth will not attack them.

CAMELLIAS UNDER VINES (*Yorkshire Amateur*).—Your idea is a good one. Camellias do well under Vines. They grow freely and flower abundantly. Plant the old Double White, Lady Hume's Blush, Bonomiana, Imbriata, Mathotiana, Lavinia Maggi, and Elegans.

REMOVING WALNUT TREE (*G. T. Wade*).—Now would be a good time to transplant; but if it has been ten or twelve years in one place it would be more satisfactory to dig round it, as is recommended for Apple and Pear trees in another place, and transplant it next year. You may now cut the branches off.

PRUNING PYRACANTHA (*Mrs. Holmes*).—It is too late to "clip the breast-wood with a pair of shears" of the Pyracantha, also the Escallonia and Cotoneaster. Cut out with a knife a sufficient portion of the shoots to enable you to secure the remainder to the wall thinly and without crowding them.

BUCKWHEAT CULTURE (*S. W. F. K.*).—The proper time for sowing buck wheat is in May, when there is no longer any danger to be apprehended from the frosts, for so tender is this vegetable at its first appearance as to be un-

able at an earlier period to withstand the vernal cold. The slightest frost in their infant state would infallibly cut off the young shoots; and as from this circumstance it must be sown at a season when dry weather may be expected, the crop on that account not unfrequently fails. The produce, which varies with the seasons (and this is rather an uncertain crop), ranges from two to four quarters per acre. It is commonly grown in England in preserves as food for pheasants and partridges. It is an excellent food for poultry; pigs thrive upon and are fond of it (it is commonly given to them mixed with potatoes), and when bruised it is good food for horses, two bushels being equal for this purpose, it is said, to three of oats (a bushel weighs about 46 lbs.). Cows when fed with it yield a large increase of milk. Sheep when fed upon the plant when in blossom stagger and tumble about as if drunk. It is sometimes made into hay, which is nutritive, but tedious to make, and should be consumed before the winter. It is often grown on poor exhausted soils and ploughed-in when in bloom; in this way it increases very materially the fertility of the soil, and is a mode often practised in Essex, Suffolk, Norfolk, and in Scotland. Mr. Ballingal has given an account of his experiments with it upon a clay loam recently limed, from the result of which he warns his brother farmers that it is "needless to attempt to grow it upon damp soils, or to expect full crops upon lands exhausted by overcropping."

PRESERVING GRAPES (*Grape-Grower*).—Nine-tenths of the gardeners in the country have no better means of preserving their Grapes than you have, but you lack the best-keeping Grape—viz., Lady Downe's. If you had given the inside border only one good watering after the Grapes began colouring it would not want more until they are all cut. If you read "Doings of the Last Week" you will find all the information about ventilating, firing, &c. You will gain nothing by bending down such stout stems as your Vines have.

REMOVING YOUNG PEAR TREES (*F. I.*).—They may be safely removed this autumn. It is not necessary to keep the union between scion and graft covered now if it has taken well; if not, tie a binding of matting round the union, not very tight.

WINTERING BEDDING GERANIUMS (*Idem*).—You had better not cut them back until the spring, as you have only cold frames to winter them in.

TRAINING YOUNG FRUIT TREES (*Idem*).—If for pyramids cut the "maiden" stem back one-third; for espaliers and cordons it ought to be cut back to 15 or 18 inches from the graft.

CRINUM CAPENSE PLANTING (*Manx Cat*).—We have had Crinum capense planted by the margin of a stream four years. It appears thoroughly established, and has flowers every year. The top part of the bulb is some 2 or 3 inches below the surface, and the soil is that of an ordinary garden border. It requires no protection in winter, and may be planted immediately.

TRITELEIA UNIFLORA (*A. Boyle*).—Triteleias are quite hardy and do not require the shelter of a frame in winter as was once supposed. Plant in rich well-drained soil, not crowding the bulbs, but afford each plant ample space for its full development, and you will have flower spikes 8 or 9 inches high. The flowers are sweet-scented and appear in early spring, continuing in full beauty for several weeks. You may plant them at the present time, including those you have in the pit.

NERTERA DEPRESSA (*A Constant Reader*).—Take shallow flower-pans and fill them with rich soil, say one part of loam and two parts old hotbed manure; pour in water till the soil acquires the consistency of mud, then prick little bits of the Nertera upon the surface; place the pots upon a light shelf in a pit or greenhouse. Keep plenty of water in the pans, and the plants will spread over the surface, flower freely in spring, and become cushions of bright little orange-coloured berries early in summer, when they may be planted-out when required for the flower beds. The plants grow freely potted in the ordinary fashion, but they are apt to bear very few berries when so treated.

AMMONIA versus SLUGS (*A Country Vicar*).—One gallon of gas ammoniacal liquor mixed with seven or eight gallons of water will kill slugs if poured on the soil, and will banish worms if applied to a lawn.

DUKE OF BUCCLEUCH GRAPE (*F. W. T.*).—The colour of the berries is pale amber.

ROSE (*H. R. C.*).—We do not think your specimen is of Narcisse, but of Isabella Sprant.

DR. HOGG GRAPE (*C. T. H. Dorset*).—Dr. Hogg Grape will ripen in the same temperature as the Chasselas Musqué. We should not graft it on that Vine. It would probably do well grafted on the Black Hamburgh, or you may plant a young Vine of it. It is a good Grape with a Frontignan flavour, and what may be termed warm Black Hamburgh treatment will suit it.

NAMES OF FRUITS (*Rus in Urbe*).—1, White Paradise; 2, Summer Golden Pippin; 3, Norfolk Stone Pippin. (*T. P.*).—1, Lady's Finger; 2, Cellini. (*G. McG.*).—2, Alfriston; 6, Northern Greening; 7, Large Hunthouse; 8, Cox's Pomona; 10, Braddick's Nonpareil; 11, Tower of Glamis. (*W. D.*).—Red Calville. (*H. J. B.*).—1, Winter Hawthornden; 2, Wormsley Pippin; 3, Gloria Mundi; 4, Not known; 5, Golden Noble; 6, Hall Door. (*G.*).—2, Minshall Crab; 3, Winter Greening; 4, Cox's Pomona; 5, Not known; 6, Russet Nonpareil. (*Spero*).—1, Not known; 2, Adams' Pearmain; 3, Striped Seeding; 4, Bess Pool; 5, Summer Pearmain. (*E. H. R.*).—1, Keswick Codling; 2, Not known; 3, Yorkshire Greening; 4, Dumelow's Seeding; 5, Cox's Pomona; 6, Ribston Pippin. (*M. A. W.*).—Hollandbury. (*E. R.*).—Trumpington.

NAMES OF PLANTS (*W. F. R.*).—Sedum carneum fol. var. (*L. H.*).—It is Honesty (Lunaria). It is quite hardy. (*R. Carnall*).—It is a Tropaeolum, but we cannot name the species without seeing a flower.

POULTRY, BEE, AND PIGEON CHRONICLE.

OXFORD POULTRY SHOW.

THE sixth Meeting was held on the 24th and 25th inst., and was by far the largest show which has so far this season been held. The arrangements were all exceedingly good, and reflected the greatest credit on Mr. King and his working Committee. All the minor details were here satisfactorily looked after, such as chaff, gravel, grass, and good food for the birds, and the exhibits were mostly very effectively staged. We much regret that the civic authorities should not take more interest in the Show, for the visitors it brings to their city and the consequent advantages for trade must be considerable.

Dorkings with four classes were the first in the catalogue where the cup pen were a pair of Darks of great merit, their shape, combs, and feet being all that could be desired. The second were very fine birds, but the pullet hardly in her full beauty. The cup Silver-Greys were excellent, the cockerel's colour being extremely good, and his pullet a great beauty in full feather and good condition. The first Alexandra Whites here again scored the similar honour, and most deservedly; they are of superb colour, and good in combs as well as being large, while the cup Cuckoos were very even in markings and large in frame. We were glad to see the quality so satisfactory in this class.

Spanish were not a large collection, but we thought the quality very good. The winners won their places easily, and we much liked the pullet in the third-prize pen.

Cochins were in excellent force, and we thought the winners well selected in each department. In Buffs the winners were the first Alexandra pair claimed there of Lady Gwydyr. They were in beautiful feather and looked well. The cockerel in the second pen was very rich in colour, and had a good-coloured pullet. In Partridges the first pullet was very good, her pencilings being excellent. The cockerel in the second-prize pen was as yet in poor feather, and requires some time to have his neck hackles down. The cup Whites were in fine condition, and though not very large deserved their place, and we are sorry to say that the tail feathers of both birds were many of them clipped by some evil-disposed person, as was, too, the fluff and side feathers of the second-prize cockerel. In Blacks the cup pen were in the best feather, but the second were the largest. The pullet here was, however, moulting her neck feathers. We were sorry to see no Cuckoos exhibited.

Brahmas mustered well, especially the Lights. The winning pullet was prettily marked, and her mate will in time probably be a good one; as yet he is rather raw in appearance. The cup Lights were much hooked or else very large, and the second and third were also good, though the latter cockerel could have been of a better colour with advantage. Mr. Lingwood's pens in both classes were empty.

Game made a great feature in the Show, and we believe the awards were on the whole most favourably received. All agreed in the great excellence of the £10-cup Black Red cockerel, which was claimed at the catalogue price of £50 during the Show. His colour, style, and shape were all perfection. The cup Black Red pullet was also very good, and this choice was again much approved of. The Brown Red cockerel which won the cup was very shapely and good in feather, as was the same exhibitor's Duckwing. In the other pullet class a Pile, very fine and good in colour was first, the same bird which won at the Alexandra, we believe. In the undubbed class a stylish Brown Red won the cup, and a good Black Red had the second honour.

Hamburgs made the finest display we have so far this season seen of the breed. The cup Silver-pencils were very pretty, and the pullet good in markings; the cockerel will look better when his tail is more matured. The cup Blacks have had the same position frequently before, and the cock is glossy and neat, but certainly too pale in the face. The Golden-spangles were good, and the pullet handsome in moons, with a good cockerel. The Golden-pencils were very strong, and there were several capital birds as well as the winners which came in for cards.

Polands were of great merit, though the Blacks were few in number. In this colour the cup pen were the whitest in crests, and deserved their position. The Silvers, too, were good, though it is doubtful if either second or third were not superior to the cup pen; but all were remarkably fine, and all came from one yard in the first place we believe. The Golds made the largest class, and the quality was very good, the third-prize pens being very even in merits and well selected.

French came to the front in a strong way. The Houdans were especially numerous and good. There did not appear to be much between the first and second, but the latter were the darker; both, however, were large, good in claws and crests. The cup Crêves were not, perhaps, the largest, but we liked them as a pair. Mr. Wood had a larger cockerel, but his tail was far too high.

Malays were extremely good, the pullets especially, there being many of that beautiful dark pheasant colour which we so much admire. The winning cockerel was a very tall and fine bird, and we thought they won easily. Mr. Hinton had a good pullet, and Mr. Downing a good cockerel.

Americans brought forty pens, and they were very fine. The Whites, though placed in a high situation, looked to advantage, and the cup pen were certainly very large and good in combs and ears. The Browns were very light in colour as far as the noticed pens went, and the fine condition of the cup and second-prize pen doubtless helped to place them.

White Silkies and *Sultans* were grouped in the upper gallery with the ornamental Waterfowl, and this department was in the evening the most crowded with visitors. The cup and second Silkies were very near each other in points, and in Sultans an old pair in very lovely feather took premier honours in a good class.

Andalusians mustered sixteen pens and made a striking feature of the Show. The winners were excellent, and were well-grown chickens; many of the other pens required more time.

In the Variety class La Flèche were first and Plymouth Rocks second, and third going to Black Minorcas. This class was not so good as many of the others in its quality.

Bantams were a good lot, but unfortunately the Game were much in the dark and could hardly have justice done to them. The winning Blacks were exceedingly lustrous and smart; and the cup Laced very beautiful Silvers, the hen finely laced and most pure in ground colour. In the Variety class very pretty Pekins won first and White Rosecombs second, White Japanese having third place.

Waterfowl were wonderfully good, and the Aylesburys and Rouens very fine indeed, the former cup pair being large and very clear in bills. The Blacks were better than we have before seen them this year. The first and second were small and bright in colour; the third were larger or else good in colour, and were claimed at catalogue price. The Mandarins and Carolinas were almost a show in themselves, very beautiful specimens of the first-named winning the cup. Their lovely condition and feather were something to be remembered. In the variety Duck class a good pen of Kasarkas came in first.

The *Geese* were numerous, and all the prizes went to Greys; while in *Turkeys* the cup pen was very fine and in beautiful condition, appearing to be at the same time very youthful indeed.

The Judges were Messrs. Hewitt and Teebay, who divided the work between them.

PIGEONS.

The Pigeons were shown as usual in the Town Hall. So popular is this Show becoming that this building, formerly amply large enough for many poultry classes as well as for the Pigeons, is now barely large enough for the exhibition of the latter and the Bantam classes.

Carriers came first as usual. Blue or Silver cocks numbered eight. The first and second-prize birds were excellent, both Blues. Mr. Fulton's struck us as the best in beak wattle, but Mr. Stretch's in colour. Fifteen Black cocks were entered. An old acquaintance won first and cup in capital trim. Second is magnificent in wattle, but not quite perfect in beak. Dun cocks numbered eight. First and second were well-known winners. We should almost prefer the latter when in his best trim. Blue or Silver hens (eleven), first very fine in form, second good in colour. Black or Dun hens (sixteen), first and cup Mr. Fulton's splendid Black, which we have before described; second a Dun with good wattle, third another good Dun. Any other colour, cock or hen (eight), first a White, better in points than Whites generally are; second and third Pies. Black or Dun, hatched in 1877, a class of twenty-nine, only four of which were noticed. We fear many birds were shown in this class which ought from their age to have been in the preceding classes. First-and-cup a capital Dun, second a nice Black, third a Black too. There were nine entries in the class for young birds of any other colour; first and third were Blues, second a good White.

Pouters had five classes. The cup went to Mr. Lang's White hen. She is a beautiful bird all round, but some breeders of coloured birds thought themselves aggrieved by the award from the additional points, difficult to produce, possessed by the coloured varieties. It may be a mistake for whole-coloured to compete with marked birds for the same cup, but when they do so we consider that the best bird of its kind should have the cup, and consequently think this award a good one. The bird was, we believe, claimed for thirty guineas. Blue or Black cocks (ten), first a Black very long in limb, second an immense Black, third a pretty Blue. Blue or Black hens (eleven), first a very pretty Blue, third a Black. White cocks (thirteen), first a very large and grand bird, second and third very fair. White hens (nine), first the above-mentioned hen; her one blemish seemed to us shortness of thigh. Any other colour (eleven), first Red, good all round; second another Red, very slim in girth, and generally thought the best bird in the class; third a Yellow.

Barbs had three classes. We have seen much better shows of this breed. Cocks (twelve), first-and-cup Mr. Headley's Black, well ahead of the rest. Hens (eight), first a well-known Yellow thoroughly out of condition, second a Black. Hatched in 1877 (eight), the winners all attractive birds and young, others in the class looked antique.

Tumblers.—Almond (eleven) were a capital class. First-and-cup a very beautiful cock, second a hen prettily marked. Young Almonds numbered only six; the first and second were very promising. Mottled Short-faced (nine), first a Black rather lightly mottled, second a Red, third a Black with too much mottling, extending over the back. Short-faced, any other variety (eleven), all the winners were Agates and beautiful birds. First a cock, second and third hens. Balds or Beards not Short-faced (ten), first a Blue Bald, second a Black Bald, third a Blue Beard. Any other variety (eight), three Yellow Mottles won.

Dragoons.—This variety had no less than eighteen classes, 232 entries, £31 15s. in prize money and four cups! Proud in-

important article of food for the poorer classes of the population, a breeding establishment was erected in a few months, with six hundred cages for that number of does, with a larger number of compartments for the young. The prejudices of the public have been combated by publications and by facts. A shop for the sale of Rabbits was opened, and in four months twelve thousand head were killed and sold. Messrs. Costamagna not only taught how the Rabbits were to be cooked but added example to precept. They distributed in various parts of Italy upwards of one thousand animals of the best breeds, and have also placed at the disposal of persons of small means one thousand five hundred Rabbit families—in all nine thousand animals—with their cages, &c. The debt thus incurred by the receivers is redeemable by a small annual quota of the products.

BEE GOSSIP.

YOUR correspondent, P. H. Phillips, describes a bar-framed hive which is in many respects similar to a hive which I described in your Journal many years ago. It is there called "the Tasmanian hive," because I first made use of it when I was resident in that part of the world. In shape it differed from the one described at page 317, inasmuch as at each end it tapered down at an angle of 45°, so that in shape it resembled somewhat an ordinary beetle trap reversed. The object of this was to facilitate the removal of the end combs. It answered well enough, but I found its great length unwieldy in my apiary, and finally it was cut back to the dummies which terminated the hive at ordinary times right and left of what Nutt would have called "the pavilion of Nature." Where, however, room is no object, I am persuaded that the principle of Mr. Phillips's hive is a thoroughly sound one; this his success in so bad a year has proved. The only hope of honey this year in ninety-nine cases out of a hundred lay in preventing all swarming and having the hives as full as possible of bees, to be in readiness for any glut of honey which might come for a longer or shorter time. Seventy-one pounds of honey from one hive is no bad result in any year. In a good year such a hive worked simultaneously with supers and side combs ought to produce almost any amount of honey, taking out combs and removing supers as fast as they were filled. In the old fashion of working supers it was always difficult to prevent swarming, owing to the bees often being overcrowded before a super was removed, as the bee-master was anxious to have it perfectly sealed-up in every part before removal.

The use of perforated zinc by Mr. Phillips also proved a success, although probably each bee found a difficulty in wriggling its body through the narrow aperture. This would appear at first sight rather an objection to the zinc, but "the proof of the pudding is in the eating." Long ago I discarded zinc feeders from observing the difficulty with which bees got their bodies over the sharp edge. It often required several efforts before they succeeded. This would be remedied in the case of the perforated zinc if it were possible to have a thick cardboard lining with holes perforated to match.

This autumn threatens badly for my bees. Usually all this month they are actively pollen-gathering from the ivy which in many years affords a considerable quantity of honey. As it is—probably owing to the ivy being late, as all flowers have been this year—perfect stagnation reigns in my apiary. No pollen-gathering means no breeding, and this again means a weakened population with which to begin the new year, and everybody knows what that promises, or rather portends, for 1878. Two years ago we had a wretched autumn, and numbers of hives perished the following spring from the same cause.

It is curious to observe the difference in queens. This year I introduced two lively young queens imported from Italy, supplanting with them two degenerate queens. One of them set to work immediately, and is the mother of a large proportion of the population of her hive. The other has remained perfectly quiescent; only yesterday for the first time did I see a pollen-laden bee enter the hive after a six-weeks reign of its imported queen. What is the cause of this strange difference? I have noticed it before, and thought the queen dead, which afterwards turned out very prolific. In this case both hives have been steadily fed, but one has taken down five times as much as the other, both being well peopled.

I may mention that, finding the less active of these Italianised stocks deficient in weight, while the bees refused to feed from the bottle, I recently adopted a plan which answers well and is particularly safe for late feeding. I screwed an eke of about 1½ inch stuff to a bottom board, which is a *fac-simile* of the one in use by this hive. Within the space I lay pieces of sound drone comb flat on the board, and carefully fill each cell with the syrup. The hive which exactly fills the eke is quietly set over it, and the old bottom board removed. As fast as the food is taken up the cells are refilled. In warm weather this method of feeding can be safely adopted throughout the winter, with the maximum of hope that the bees will store away enough food, and the minimum of risk of all other dangers.—B. & W.

OUR LETTER BOX.

THE PIGEON FANCY (J.).—General complaints are of no influence. We will readily insert any statement of actual wrong.

EGGS IN WINTER (L. H.).—We have had a fair supply of eggs from Brahmas. Fowls do not injure ivy.

PIGEONS (J. E.).—"The Pigeon Book" can be had from our office if you enclose twenty postage stamps with your address. The Blue Rock would suit you.

GRANTHAM SHOW.—S. Woodhouse, Esq., Mapperley, asks for the Secretary's name. A letter addressed to "The Secretary," we think would be delivered to him.

BAR-FRAMED HIVES (W. H. Attwood).—Your hives 18 inches square and 11 inches deep, if inside measure (clear), we think too large. But the size of hives must be regulated in great measure by the productiveness of the country. Here we find the Woodbury size fully as large as our most favourable seasons authorise us to use—namely, 14½ inches clear, and 8½ inches deep. By no means transfer your bees at this time of year, it would be ruinous to them. Wait till May, or April at the earliest, and do it in warm and sunny weather.

CANARY SUFFERING FROM ASTHMA (M. H. Bath).—From the description given of your "old pet," we believe the bird is suffering from asthma, and we think there is but slight hope of the objectionable noise abating, unless death ensues. The causes of the disease may be easily accounted for. The occasional "throwing-off of feathers" has been brought about through the bird being suspended from the upper part of the room, and breathing a high temperature during the time the fire and gas are lighted, and then afterwards during the night time combating with a temperature many degrees lower. Such treatment is "enough to kill a horse." However, supply the sufferer freely with plantain seed (upon the stems which may be obtained in abundance just now), and plain biscuit steeped in sherry, likewise about twice each week give the bird a drop of cod liver oil so administered that the oil may be deposited in the bird's throat instead of upon the feathers surrounding the beak, which can easily be opened with a large needle or bodkin. Whilst the beak is moderately opened let a careful assistant deposit the oil in the throat from a thin quill or skewer. For an occasional diet give bread and milk. If you have not a cat the bird will breathe purer air if you lower the position of the cage about a couple of feet, but keep the invalid out of draught, and let it roost with a cloth over the cage during night time.

REMARKS.

- 24th.—Very fine sunny day; rain at 7.30 P.M., and nearly all the rest of the evening; fine night.
 25th.—Rainy morning, wet and dull day; fine at night.
 26th.—Close damp morning, finer afterwards; foggy from 5 P.M.
 27th.—Wet morning, slight sun at intervals from 10 A.M. to noon; very heavy rain from 2 to 2.50 P.M.; fine night.
 28th.—Very fine day; misty in evening.
 29th.—Damp, dull, and wet day; very warm in the evening, the temperature at 9 P.M. being 57°.
 30th.—Overcast in morning, slight sun at intervals, and very windy after 5 P.M. A dull damp week, and at times windy.—G. J. SYMONS.

COVENT GARDEN MARKET.—OCTOBER 31.

TRADE quiet. We have no alteration to report from last week.

From observations taken near London during forty-three years, the average day temperature of the week is 43.8°; and its night temperature 34.9°.

APPLE ELECTION.

HAVE received twenty-five lists, and another year I hope many other lovers and cultivators of the Apple will assist. At the same time I think the result will be of use to many intending planters, and also an aid to growers for grafting and other purposes. There will be many an opportunity for discussing the relative merits of the Apples in the lists, but as planting time is approaching, I will make a few observations on the leading sorts

as a guide to small growers—that is, growers of a few sorts. I only consider the result of the election as a very small guide to the orchardist as to planting for profit; but at the same time I think it shows the merits of the Apple as an Apple for profit and merit combined.

In the dessert kinds I have received the names of ninety-two sorts; I have included thirty-two in the lists, leaving off with those that had received four votes. The Blenheim is at the head of the list, not on its merits as a dessert Apple, but on the votes awarded in both kinds, and if left in the two lists it would not have had due justice rendered to it. Cox's Orange Pippin, there is no doubt, is now the king of dessert Apples. I believe it will do well either as a standard or pyramid. The Ribston will still remain with us (although I should not recommend it for planting), while its merits for flavour are handed down to successive generations. It is impossible to discuss the merits of all the kinds at this time, but for bearing in succession I have found the summer Golden Pippin, King of the Pippins (now ripe), Court-Pendu-Plat, and Sturmer, generally have a crop. In kitchen Apples it is a curious coincidence that the number receiving four votes should be within one of the dessert—viz., thirty-three. There is another fact, that two kinds stand far ahead—viz., Wellington (Dumelow's Seedling), and Lord Suffield. If I had to choose two more sorts for a small grower that would be constant bearers I should take Cellini and Beauty of Kent. But there is one point in relation to cooking Apples that I should like to see carried out, and that is the result of the cooking of a certain quantity of the best known Apples by measure, and I think it would be found that many of our sorts, although producing a quantity on the tree, would not make much apple sauce.

There are many kinds of Apples that do better grafted on another stock. The best to plant for stocks are Goff, Cellini, and Beauty of Kent, and many sorts will grow on these stocks that refuse to bear on any others. I have many notes that I shall be pleased to place before your readers in future numbers, but I do not think the publication of the result should be deferred, and therefore send it for publication this week. I only hope it may be the means of enlarging the knowledge of Apple-growers as to the best sorts to grow and the best means of growing them.—LEWIS A. KILLICK, Mount Pleasant, Langley, Maidstone.

ECONOMY IN HEATING GREENHOUSES.

Now that the time has again arrived for the heating of greenhouses and other glass structures by artificial means it may not be out of place to say a few relative words, but more especially in reply to the remarks of "RESPICE FINEM" which appear on page 246 of a recent issue of this Journal.

"RESPICE FINEM," in the first chapter of his Three-years Experience in a Greenhouse, gives an interesting account of the ways and means of erecting his house, and I would say that amateurs who have the time and ability (for it is not everyone who is blest with either), and are desirous of putting up a similar house as cheaply as possible, cannot do better than follow him in his *modus operandi*; but I am afraid that few if any of us amateurs will care to follow in his footsteps as to heating them. By this I do not so much mean the apparatus by which they are heated as the cost of doing so.

Roberts's patent terra-cotta stoves such as used by "RESPICE FINEM" are, if I mistake not, intended to be, and from all I have heard of them if properly handled are no doubt, fuel-economisers; and therefore I read with considerable surprise that it had cost him £2 15s. for heating his small house during a period of eight months. I could scarcely think that possible; but notwithstanding the amount seemed to me large at the time, on calculating what would be the cost per hour for the period stated I find it is a trifle under one-eighth of a

No. 1519.—Vol. LVIII., Old Series.

penny, which does not after all seem very much, yet compared with the outlay for heating my house it is excessive.

While it cannot be for a moment doubted that "RESPICE FINEM" went the right way to work in erecting his house, it appears to me that he did not do so in feeding it; and therefore I beg to offer to him, and others who may feel enough interest in the matter, some notes as to the way in which I heated mine at much less cost for the years 1876-7, while at the same time maintaining an average temperature of 50° throughout three seasons of the year—i.e., autumn, winter, and spring.

My house is considerably larger than that of "RESPICE FINEM," being 15 feet long by 8 feet wide, and the heating apparatus consists of a brick flue, once straight through the house, the furnace being inside the house but fed from the outside. For heating this, and keeping up the temperature named, what was the outlay? Why, not more than £1. And of what did the fuel consist, and how much? The answer is, one and a half chaldron of coke breeze supplied me by the gas company here at 8s. per chaldron delivered to my house (I could get it for 6s. per chaldron were I to send to their yard for it), and allowing for wood and a sprinkling of coal wherewith to speedily light the fires, I make up at the very outside 20s.,—a saving of nearly two-thirds on the outlay of "RESPICE FINEM."

Now, it is not only the cheap and at the same time excellent fuel so obtained which brings about so small an outlay. The secret in economising is also to be found, to a great extent, in the attention and care bestowed on the firing and the regulating of the damper in the chimney. In my case I take care that the furnace is well cleared every morning of all cinders and ashes, thus causing a free draught, and the throwing away of all clinkers, to make which breeze has a great tendency; and if they remain to be used again with the fuel for fresh fires the latter will be deadened and the flue not properly heated, no matter how much the fire may be stirred up. In starting the fires let the damper be drawn out as much as possible, but when well up the furnace may be filled with fuel and the damper closed to within 1½ to 2 inches (enough for the escape of all smoke), thus retaining all the heat within for the purpose for which the same is required. As to the fuel itself, there is none in my opinion to equal the breeze either for its cheapness or good qualities. I do not mean to use anything else, and I think I may safely say to all whom it may concern, it is the cheapest and the best fuel for all lovers of flowers to use who have places to grow them in other than the garden during the few summer months with which we are now favoured.

My house is only now one year old; my experience in it is therefore short, but it has been of a practical nature, and I will on some future occasion render an account thereof. It may interest some of my fellow readers of these pages who like myself are but amateurs.—L. HAKEMAN, *Bromley, Kent.*

NEW FANCY PANSIES AT PINK HILL.

WHEN visiting Edinburgh some time ago I had the pleasure of a "look round" the Pink Hill Nursery, and of enjoying a hearty shake of the hand with one of the heartiest of florists—John Downie. I observed many "good things" there—flowers which to my mind have something more sterling and satisfying about them than Geraniums, Calceolarias, and Golden Feather—such plants as Pentstemons, Phloxes, and Pansies.

Nothing attracted my attention at Pink Hill more than the seedling beds of fancy Pansies. They were growing with the luxuriance of Watercress, and flowering with the profusion—well, of Violas. And such flowers! The size and substance of some of them, together with their bold quaintness and marvellous variation of colour, are not soon to be forgotten. Why are not these beautiful flowers more generally grown? "Oh!" someone may possibly reply, "they are northern flowers and do not flourish in the sunny south." To this my reply is that I have grown them three hundred miles south of Edinburgh, and this not on the moist west, but on the drier east coast, and have found them capable of yielding much pleasure to the owner, attracting a large share of attention from visitors, and recommending themselves as worthy of being taken away in the form of "a few cuttings" by all who had the luck to obtain them. The truth is they will grow and flower as well in the south as in the north, but not so long; long enough, however, quite long enough, to be worthy of their room and

cost, and to give other flowers an opportunity of having their "turn" of appreciation.

Fancy Pansies are the most free in growth of all the types of Violas and the most gorgeous in colour—gorgeous but not gaudy, for many of them are extremely chaste. They like a generous soil and cool: afford them this, and the protection also of a few pegs or sticks to prevent them being broken by the wind, and they will give an ample return in any county in the three kingdoms. The great point to attend to is to plant them early. If very choice they should be wintered in pots in a cold—quite cold—frame, and be planted out on the advent of genial weather in spring. Late spring planting is a fertile cause of Pansy failures.

Since inspecting the striking beds of seedlings the work of selection has been going on, and the following varieties have been named as worthy of heading the list in the class to which they belong—the latest and the best of their tribe.

Mr. Jamieson.—Rich golden yellow; the finest of its class that has yet been raised. It has won three first-class certificates.

Mrs. Scott Plummer.—Bronze and yellow, with a large crimson-maroon blotch. A splendid variety, having been twice certificated.

Mina.—Pure white and purple, clearly and charmingly laced.

Mr. Comfort.—Deep rich bronze with a bright yellow eye.

John Beveridge.—Bronze lilac shaded with blue; of excellent form and attractive.

Iago.—Yellow, slightly edged with white; novel and chaste.

Mrs. Forbes.—Creamy yellow; upper petals rosy crimson.

Mr. A. Douglas.—Pure white, of fine form and good substance; very chaste.

Such are the cream of the Fancy Pansies at Pink Hill—Mr. Downie's "latest out," and particularly worthy of "honourable mention." I have a few other new flowers in my pocket book, but they must remain there for the present.—NOMAD.

VEITCH'S NEW SELF-PROTECTING AUTUMN BROCCOLI.

THE Autumn Giant Cauliflower is now nearly over, but it will not be much missed, as we have several patches of the new Broccoli just beginning to turn in. When growing the leaves of the Broccoli are more twisted over the flower than those of the Cauliflower, consequently it is better protected. The seed from which the plants were raised that are now producing heads was sown on the 16th of March, and the plants were transferred from the seed bed to their present quarters on June 6th. I send you a specimen, which I think you will say surpasses Messrs. Veitch's catalogue illustration of it. I did not expect it became so handsome.—J. MUIR, *Margam Park.*

[The Broccoli sent is extremely fine and well protected with foliage, and, as you say, "surpasses the illustration" of it.—EDS.]

THE ROSE ELECTION.—No. 5.

NURSERYMEN'S VOTES.

THE Roses in the following returns are placed in the order of merit—namely, the first best twelve, the second best twelve, and the third best twenty-four varieties, except where otherwise expressed.

Mr. CURTIS, Devon Rosery, Torquay.

Best forty-eight exhibition Roses, approximating to their order of merit as grown in Devonshire.

I had thought that the ultimate result of the poll, I mean the best forty-eight, might be compared with some degree of interest with the best forty-eight selected by a rosarian across the Atlantic. Accordingly I wrote to Mr. Ellwanger of Mount Hope Nurseries, Rochester, New York, to whom those who have been desirous of seeing the age of Roses and the raisers' names are, as well as myself, very deeply indebted; and I now place side by side his forty-eight in order of merit and the collective election forty-eight:—

The Election List.

1. Marie Baumann
2. Alfred Colomb
3. Charles Lefebvre
4. La France
5. Maréchal Niel
6. Baronne de Rothschild

44. Madame Berard
45. Madame Trife
46. Maurice Bernardin
47. Reynolds Hole
48. Marie Finger

Mr. Ellwanger's list is placed in order of merit, and it will be seen that in his selected forty-eight he has named twenty-

nine of those selected by the various electors. His list, as compared with ours, is chiefly remarkable for the Tea element, for counting *Maréchal Neil* there are eleven as against six in our list. Mr. Ellwanger further adds that he has bracketed Charles Lefebvre and Ferdinand de Lesseps, because, "though not the same," they "at many times strongly resemble each other, and I couple them as being of equal value." He also further adds—and the remark is of interest, touching the effect of climate on different yet similar Roses—"In relation to *Mdlle. Eugénie Verdier* and *Marie Finger* I would say they are with us quite distinct sorts; the former I consider decidedly the more refined and beautiful."

Here let me close the first exhibition Rose election. It will be a fair guide to the general public. In closing it I again desire to express my sincere thanks to those who have assisted me by voting papers; to several, unknown to me save through the pages of "our Journal," I desire to acknowledge very gratefully their private letters of thanks to me. I apologise to them for my seeming neglect in not doing so on receipt of the same; but time, not the will, fails me. Again sincerely thanking all, I close the election of 1877.—JOSEPH HINTON, *Warminster*.

LODDINGTON SEEDLING APPLE.

Synonyme, Stone's Apple.

AN Apple was lately exhibited before the Fruit Committee of the Royal Horticultural Society by Mr. Killick of Langley near Maidstone, under the name of *Stone's Apple*, and which was awarded a first-class certificate. The original tree was discovered on the farm of Mr. Stone at Loddington, about five miles from Maidstone, and its great merit as an orchard fruit caused it to be propagated in the immediate neighbourhood; but till within the last few years it has not been known out of

and prominently plaited or ribbed basin. Stalk half an inch to three-quarters long, slender for the size of the fruit, and inserted in a deep, wide, funnel-shaped cavity, which is lined with pale ashy russet extending over the base of the fruit. Flesh very tender, and with a pleasant subacid flavour.

This is an early culinary Apple of great excellence, coming into use in September.

The following communication was received from Mr. Killick:—"I have carefully examined the tree from which this sort originated. It is in the parish of Maidstone, but five miles off, at Loddington, a hamlet in connection with that parish. My authority for its history is a man who has had charge of the farm for twenty-two years. He tells me that at that time it was as large as it is at present, and has borne every year since. His old master did not remember it being planted, and that would carry it thirty years more. The tree is not a large one, and many sorts at twenty years would occupy as much space. The diameter of the head would be about 15 feet, and the circumference of the stem about 3 feet 6 inches. Every original graft in this district was taken from that tree, and its growth is entirely confined to this district. The tree when first planted makes a good start for the first few years, and then goes into bearing, and very rarely increases much in size. It is, therefore, very suitable for small gardens. I have some trees of this kind that for eight years have not increased in size but have cropped every year. I should recommend it planted thickly for growing for profit, and to put in an odd corner for every grower of the Apple."

PRUNING AND RENOVATING CONIFERS.

"A COUNTRY VICAR" asks for advice about pruning Conifers and the treatment of an unhealthy *Picea Pinsapo*. The subject is one of importance, for serious mischief has frequently arisen through ignorance in both these matters.

Of the *Picea* it is stated that it was an exceedingly symmetrical specimen with very dense branches. Some years ago its leader was killed by frost, and it has since then deteriorated, losing many of its interior branchlets, and it has now three leaders. How shall we treat this tree in order to reclaim it from its sickly condition, and impart vigour and symmetry to it once more? Fasten a stout pole to the stem, pulling the best leading shoot as near to it as is possible, securing it firmly in that central position, cutting off the other two shoots, and cutting nothing else, for depend upon it no pruning ever brought back health to a sickly Conifer. It is the roots that are at fault, and this is the point to which I wish to draw especial attention. Conifers have been planted anywhere and everywhere. If the soil was thought unsuitable, stations of prepared soil have been made, the trees planted, and all has gone well till the roots have exhausted the nutriment of the good soil; then, if matters are left to chance, deterioration follows, the growth becoming stunted, the interior branchlets dying and falling off till the tree becomes so thin that, as "COUNTRY VICAR" says of

his *Picea*, we can see the light through it. The remedy is as simple as it is sure. Give the roots more good soil, see that there is no risk of any accumulation of stagnant water about them, and a couple of seasons' growth will restore the lost clothing of branchlets and free strong leading shoots. The best way to apply fresh soil is by surface-dressing and excavating a wide trench for its reception in a circle around the station, and there cannot be a better time than the present for doing it. I must confess to a feeling of surprise at *Picea Pinsapo* losing its leader from frost. *P. Cephalonica*, which it much resembles, often does this, but *Pinsapo* is so hardy as never in my experience to be so affected.

Pruning Conifers is altogether a mistake. If the side branches ever show a tendency to spread at the expense of the leader, simply nipping off the tips tends to check them sufficiently. The growth of almost all of them is naturally so symmetrical that no improvement can be effected by pruning—rather the reverse. I have for the last seven years

Fig. 68.—Loddington Seedling.

its own neighbourhood. Now, however, it is to be found in some of the orchards of the adjoining parishes, and its cultivation is becoming more and more extended. Its great merit is the early bearing quality of the tree, the great size and earliness of the fruit, and its excellence as a culinary market variety. The habit of the tree is medium-sized and compact. It does not produce long rampant shoots; but, on the contrary, when it has come into full bearing it produces little wood, but keeps on forming an abundance of spurs.

Fruit large, varying from 3 to 3½ inches in diameter; roundish, slightly flattened and narrowing abruptly towards the eye; it has obtuse ribs on the sides, which become more distinct towards the eye, where they form ridges round the crown. Skin smooth and shining, grass-green at first, with a brownish cheek; but after being gathered it becomes a fine lemon yellow, with a pale crimson cheek, marked with broken streaks of dark crimson; the surface is strewed with minute russet points. Eye closed, with convergent leaf-like segments, set in a deep

watched the rapid progress of two magnificent specimens of *Cupressus macrocarpa* growing in a small roadside garden at Maresfield, which I occasionally pass, and great was my astonishment and regret last spring to find that some "improver" had pruned one of them from bottom to top, shortening all the branches by about one-third, and for the time quite spoiling its appearance. It has, however, made a vigorous growth this season, but it will require two or three years to recover its full beauty, and no permanent harm is likely to follow this rude treatment. Such is not always the case, and the experiment is a very dangerous one, for the wounds, especially of large branches, usually bleed so long that the health of the tree is seriously affected, and it does little, if any, good afterwards.—EDWARD LUCKHURST.

NEW ROSES.

At this season of the year, when amateurs are looking round their gardens and planting new Rose beds and filling-up gaps in old beds, the following remarks on a few of the more recent additions to the Rose world may be useful. I think all growers will agree with the remark that the latest novelties are nothing very startling; however, let me commence.

Auguste Rigotard, somewhat in the way of Alfred Colomb but duller in colour, yet a better grower, is decidedly worth buying.

Capitaine Christy has been very fine this season, has not quite shape enough, but is a very showy Rose; it is just what one would imagine a cross of La France and Baronne de Rothschild would produce, having at times a wonderful resemblance to each.

Comtesse de Serenye has established itself as a first-class flesh-coloured Rose, large compact form, of splendid shape, good grower, and is a real improvement.

Hippolyte Jamin is a round-shaped Victor Verdier, a strong grower (as are all this class), free bloomer, and altogether good.

Monsieur E. Y. Teas is perfect as to shape, but a wretched grower; very good if taken great care of.

Abel Carrière is truly grand, being a fine-shaped dark Rose in the way of Baronne de Bonstetten, more of a claret colour and much larger, and should be in every collection. Jean Liabaud and Jean Soupert are the same class, the latter is too small. Abel Carrière is decidedly the best of the three.

The much-vaunted Duchesse de Vallombrosa seems to me a rank impostor; it is a dull sort of flesh-colour, having none of that beautiful gloss seen in such Roses as Baronne de Rothschild. I cannot see the good of having this Rose when one can grow the Baronesse and La France.

Duke of Connaught is a red Lord Clyde, but of much finer shape, very vivid, first-rate grower, and a real improvement.

John Stuart Mill is good; more fit for garden purposes than exhibition.

Sir Garnet Wolseley, one of the Maurice Bernardin class, is of great merit.

Mdlle. Prosper Langier is too flat, but fine in colour.

The foliage of Star of Waltham is tremendous, the bloom seems ashamed of itself for having such leaves. The second flowers, however, opened better. It requires to be seen another season before expressing a decided opinion.

Sultan of Zanzibar has been this season small and ragged. I should say it will not make a mark. The reverse side of the petal is a dull red, and the slightest change in temperature causes it to fold inwards, which is anything but pleasing.

Cheshunt Hybrid holds its own right well; it is a capital grower, very free bloomer, and should be had by everyone.

Perle des Jardins is a grand deep yellow Tea, holding its blooms well up (a great consideration in Tea Roses); it gives one an idea of Maréchal Niel and Madame Falcot mixed. It is one of the finest Roses lately introduced.

Perle de Lyon, in the same way but much smaller, is also of great merit.

Jean Ducher, another first-class Tea, has the same vigorous erect growth as the two last named. In colour it resembles Adrienne Christophe, but is a much better grower.

Marie Guillot is a splendid pure white, like Niphetos only rounder and better held together; this is certificate enough for any Rose.

Emily Laxton is very like Marquise de Castellane, but bolder in petal. Although first-rate in the half-open state I cannot see that it is much of an advance.

Marchioness of Exeter is somewhat similar, rounder, and much smaller. I should say if grown by average amateurs that it would be a failure.

John Bright, very bright, but nothing else, as it is very thin.

It seems to me from personal observation this season that of late only three first-rate Roses have been added to the list—viz., Duke of Connaught, Perle des Jardins, and Abel Carrière.

If amateurs would only compare notes a little more, and form opinions of their own instead of taking everything from catalogues, we should never see gardens filled with Roses that are good only in price, and doomed to disappear altogether after a season or two. If Roses are worth growing they are surely worth growing well; and I ask, How is it that amateurs will go taking down names at exhibitions instead of trying to see the plants growing? Speaking personally, I know that an afternoon spent at a Rose nursery has often saved me a season's unhappiness.—AN OLD ROSE-GROWER.

ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 6TH.

A dull day but by no means a dull meeting has to be recorded. The rain poured steadily down, but did not deter horticulturists from attending, for the company was good and the Council room was filled with excellent collections, including plants, cut flowers, fruit, and vegetables.

FRUIT COMMITTEE.—H. Webb, Esq., V.P., in the chair. Six Pine Apples, the united weight of which was 27½ lbs., were sent by Mr. J. Hudson, The Gardens, Gunnersbury House, Acton. They were excellent examples considering the time of the year, and a silver Banksian medal was voted for them by the Committee. A large Charlotte Rothschild Pine was sent by Mr. J. Dinsmore, gardener to J. F. Blackwell, Esq., The Cedars, Harrow Weald, but it was not in good condition.

Three very good bunches of Golden Hamburg Grape were sent by Mr. J. Hudson; they were in good condition, and received a cultural commendation. Two bunches of Muscat of Alexandria were sent by Mr. J. Atkins, gardener to Col. Loyd Lindsay, Lockinge Gardens, Wantage. The berries were large and beautifully finished, and the Committee voted that a bronze medal be awarded for them. Mr. W. Wildsmith, gardener to Lord Eversley, Heckfield, sent three bunches of Gros Colman; the berries were very large, but not quite so well finished as Mr. Wildsmith has shown them, yet they well deserved the cultural commendation awarded to them. Harrison Weir, Esq., Brenchley, Kent, sent very good examples of Muscat Champion from a ground vine, and a cultural commendation was awarded to them. Mr. Weir also sent a good dish of Mrs. Pince's Black Muscat.

A dish of Salway Peaches was sent by Mr. W. Tillery, The Gardens, Welbeck. They were good-looking examples, but rather over-ripe. A green-fleshed Melon named Exquisite was exhibited by Mr. C. Tyler, gardener to R. Gosling, Esq., Hassobury, Bishop Stortford. It was, considering the lateness of the season, of remarkably fine flavour. It received a first-class certificate. Mr. E. Bennett, The Nurseries, Rabley, sent a dish of Strawberry Garibaldi, for which a letter of thanks was directed to be sent. Mr. David Ward, florist, Wisbech, sent a seedling Pear of the Bergamot type, but it was not in good condition. As a rule Pears are not good this year. Mr. C. Penny, The Gardens, Sandringham, sent two dishes of seedling Apples, but they were not considered of special value. Mr. Douglas, Loxford Hall Gardens, exhibited Waldron's Seedling Apple, but it was not thought equal to existing sorts. Mr. Dancer, Chiswick, sent a good dish of Cox's Orange Pippin, for which the Committee awarded a vote of thanks. Barnack Beauty Apple from Mr. R. Gilbert of Burleigh, Stamford, was a fine-looking fruit but not of good flavour.

Mr. Gilbert also sent selected Brussels Sprouts on the stalk; the sprouts were certainly very fine and afforded evidence of superior culture. A letter of thanks was voted. Veitch's Autumn Cauliflower in fine condition came from Mr. T. B. Wilson, Claydon House Gardens, for which a vote of thanks was given. Mr. R. Dean of Ealing sent a specimen of the long ribbed Marrow, which was passed.

Messrs. Hooper & Co., Covent Garden, on behalf of Messrs. B. K. Bliss & Sons, New York, sent a collection of Potatoes, and from Mr. R. Dean came a small collection of new sorts, the skins well washed and polished. We think it is far better to show them more rough in the skins, as the character of the Potato cannot be determined when the skins are made so glossy. Messrs. James Carter & Co. exhibited an extensive and excellent collection of Potatoes, numbering about 150 varieties, every dish of which was in the best exhibition character. It was a highly meritorious display.

FLORAL COMMITTEE.—G. F. Wilson, Esq., F.R.S., in the chair. A beautiful group, including choice Orchids, Ferns, Sarracenias, Droseras, Zonal Pelargoniums, &c., was arranged by Messrs. Veitch, Royal Exotic Nursery, Chelsea. Amongst the Orchids we noticed *Cattleya labiata*, *Oncidium incurvum*, very chaste; *O. crispum*, and *O. varicosum*, very fine; *Cattleya marginata*,

Lælia Perrini, *Odontoglossum cirrhosum*, *Colax jugosus*, *Oncidium Welfoni*, and the charming Indian *Crocuses* (*Pleiones*) *Wallichiana maculata* and *lagenaria*. *Stenia fimbriata* was singular by its beard-like lip, and *Stelia Bruckmulleri* by its small triangular-shaped flowers. *Cypripediums Sedeni*, *Schlimii*, *Arthurianum*, *insigne Maulei*, *selligerum*, *marmorophyllum*, *tesellatum*, *euryandrum*, *Crostanum*, and a new variety, *C. ænanthum*, the result of a cross between *C. insigne Maulei* and *C. Harrisianum*, a rich maroon, sepals margined with white, proved their great decorative usefulness. *Calanthes Veitchii*, *Sedeni*, and *vestita rubra* were represented in the group. Amongst the Ferns were an elegant specimen of *Adiantum speciosum*, *Lomaria discolor bipinnatifida*, *Osmunda palustris*, and *A. Luddemanniana*. The *Geraniums* *Heather Bell*, *Atlanta*, *Amazon*, and *Egeria*, raised by Dr. Denny, were all excellent. A medal was recommended to be given for the collection.

Mr. Ollerhead, gardener to Sir Henry W. Peek, Bart., M.P., Wimbledon House, staged a bright, varied, and beautiful assortment of Orchids. The *Pleiones* were excellently grown. *Asanthes*, *Cypripediums*, *Vanda carulea*, *Cattleya Dowiana*, *Dendrobium formosum giganteum*, *Odontoglossum Roezli*, and *Miltonia Morelliana* were noticeable in this creditable collection, for which a vote of thanks was worthily awarded.

From the collection of Sir Trevor Laurence, Bart., M.P., Burford Lodge, Dorking, came a splendid example of *Oncidium crispum*, with six robust spikes and probably three hundred flowers, for which Mr. Spyers, the grower, was deservedly awarded a cultural certificate.

A remarkably fine example of *Vanda carulea* with six spikes and eighty-nine flowers was exhibited by Mr. Smith, gardener to C. Lane, Esq., Badgemore, Henley-on-Thames. It afforded evidence of superior cultivation, and the Committee recommended that a medal be awarded by the Council to Mr. Smith.

Mr. R. Parker, Exotic Nursery, Tooting, exhibited an extensive and attractive collection of hardy cut flowers. The varieties of *Chrysanthemum indicum* proved their value as border flowers—notably *nanum*, silvery white; *Frederick Pete*, crimson; *Hendersonii*, yellow; and *Scarlet Gem*, reddish crimson. Amongst the *Asters* (*Michaelmas Daisies*) *A. Nova-Anglie*, *A. spectabilis*, *A. Novi-Belgii*, *A. Amellus*, and *A. laxus* were fine; and the smaller *A. ericoides*, *A. Reevesii*, *A. discolor*, *A. pendulus*, and *A. multiflorus* were also very elegant. *Rudbeckia hirta*, *Chrysanthemum lacustre*, *Tritoma grandis*, *Schizostylis coccinea*, *Trollius asiaticus*, and *Gynerium argenteum album* were very striking; *Helleborus niger maxima* was extremely fine; *Colchicum autumnale flore plenum*, rosy lilac; and *C. a. album plenum*; *Pansy Queen*, creamy white with purple blotch; *Viola Sir Walter Scott*, purplish violet; *Aponogeton distachyon*, very fine; *Physalis Alkekengi* (Winter Cherry), and *Violet The Czar* contributed to this fine November display. A vote of thanks was deservedly recorded by the Committee.

Mr. Smith, Ealing Dean Nursery, Ealing, sent a collection of *Cyclamen persicum*. Some of the flowers were very large and all good. The foliage was well marbled, and an agreeable perfume pervaded the group. The colours were varied and the collection attractive. A vote of thanks was awarded.

Mr. Cannell, The Nurseries, Swanley, Kent, sent cut trusses of twenty-four varieties of zonal *Pelargoniums* quite as fine and as richly coloured as if exhibited in July. *Jean d'Arc*, pure white; *Fairest of the Fair*, white, salmon eye; *Mrs. Leavers*, rich rosy pink; *Louisa*, lilac pink; *David Thomson*, crimson; and *The Shah*, deep scarlet, were extremely fine. *New Life*, the remarkable striped variety, was also exhibited. A vote of thanks was awarded.

Messrs. E. G. Henderson & Sons, Pine Apple Nursery, Maida Vale, were awarded a vote of thanks for a stand of Japanese *Chrysanthemums*. *Gloire de Toulouse*, purplish crimson with white spots, is distinct and good; *Harlequin*, silvery pink; *Fulgare*, rosy pink; *R. T. Biggs*, crimson scarlet, were the more noteworthy varieties. A vote of thanks was awarded. Mr. Davis, Park Nursery, Plumstead Common, exhibited a stand of incurved *Chrysanthemums*. Mr. R. Dean was awarded a vote of thanks for *Godetia Lady Albemarle* grown in a pot; the plant was very dwarf and attractive.

Primula capitata from the Society's gardens was exhibited. It is a charming species, the leaves growing close to the surface of the pots, the flower trusses being borne on farinose stems. The trusses are as globular almost as large heads of clover, colour like mauve; a very charming alpine plant. A first-class certificate was awarded. First-class certificates were also awarded to Messrs. Veitch for a fine Tree Fern, *Dicksonia Berteroana*, from Juan Fernandez. It is a stately plant with robust spreading fronds of great substance and elegance; and to *Sarracenia Cheloni*, the result of a cross between *S. rubra* and *S. purpurea* with purplish crimson pitchers.

BOCCONIA JAPONICA.

This is one of our most stately and majestic-looking hardy herbaceous plants, and it is very surprising that in these days

of subtropical effects *Bocconia japonica* has not found a more prominent position. In fact, one may visit a hundred gardens and not see a plant of it; and recent works on hardy plants have omitted to notice it at all. There is scarcely another hardy herbaceous plant that is so far removed from what is termed a weedy appearance, nor one that has larger or more elegantly pennilobed foliage. In good soil it grows to the height of 6 to 7 feet, producing spikes of elegant creamy-white flowers from 1½ to 2 feet long. It lasts a long time in flower, and for centres to large clumps or back lines there are few more effective plants. It masses by itself, it has much more of a subtropical appearance than many tender plants used for that purpose. No garden should be without this plant.—T. M. (in *The Gardener*).

GRAPES CRACKING.

PROMINENCE has been given to the mysterious subject of Grapes cracking, and I for one consider that both the subject itself and the letter of "J. S. W." are worthy of their position on page 7. I shall await with a little anxiety Mr. W. Taylor's reply, for I think he has found a "foeman worthy of his steel," which is not a small compliment, and the reply I am anticipating cannot fail being instructive.

"J. S. W." has broached a somewhat new theory of the cracking of Grapes, and his remarks on the juice not issuing out of the split berries are certainly significant. I am inclined to agree with your correspondent that cracking does not necessarily result from the "force of sap from within." My reason for this is that the finest crop of Madresfield Court Grape that I ever saw was produced by Vines in great luxuriance, and which received more water at the roots than falls to the lot of Vines generally. There was a great force of sap in the case of these Vines, but much of it was doubtless dealt with by the foliage, which was ample, for the laterals were not all stopped at one joint beyond the bunch, but two or three joints were left according as there was room for the leaves to expand. That, however, was not the sole cause of the immunity of the Grapes from cracking, because I have seen other crops which have been similarly treated in respect of summer-pinching ruined by the splitting of the berries, and on the other hand I have seen sound crops under a close system of pinching. It is this—the presence of cracking under various aspects of summer-pinching—that has shaken my confidence in the "inner propulsion" theory.

When the owner of the Vines in question was advised by the writer to water his borders thoroughly just when the Madresfield Courts were showing colour, he expressed his fear of doing so on account of accelerating the splitting of the berries. The borders, however, were thoroughly watered, and not one berry cracked. The force of sap was, I know, considerable, for the berries swelled to a great size, and they coloured admirably. Their colouring may not afford evidence of the great propulsion of sap, but the matter is worthy of mention simply because they did colour under the treatment given, and that was not a dry, but a comparatively moist atmosphere. I may be wrong, but I have an idea that it is owing to a reasonable degree of atmospheric moisture that prevented the Grapes from splitting.

I think it is admitted that there is great difference in the skins of different varieties of Grapes. Some are thick, leathery, and opaque; others thin and transparent. The effect of the atmosphere, too, is different on these different cuticles. Under a very dry air the thick skins appear to turn soft, the thin skins brittle. The subject may, perhaps, be made more clear by a very familiar example afforded by very common material—paper. Thick brown paper when it is very much dried is not necessarily rendered brittle, but thin glossy paper is so brittle that it tears almost by a touch. Are not the skins of Grapes affected much in the same manner? I think so, and acted on that thought when I advised the atmosphere of the house of Madresfield Courts referred to to be kept moderately moist throughout the whole colouring and ripening period.

Usually the air of vineries is kept moist, in some cases very much so, when the berries are green, but on the first signs of colour moisture is withheld lest the fruit should not "finish" well. A diminution of moisture at that period may be advisable, but the sudden withholding of it entirely is another matter, and especially when coupled with what is not at all an uncommon circumstance—increased ventilation. I cannot conceive it sound practice to keep the air of a vinery almost

as aqueous for six weeks as that of a swamp, and then to suddenly transform it into the atmosphere of a desert—exhaustive and dry. Some Grapes will endure a change so violent, but all will not do so; the skins of the berries become suddenly dry and lose their elasticity—their expansive power, turn brittle and crack; just the counterpart, as “J. S. W.” has so well put it, of “chapped hands.” The simile may, perhaps, provoke a smile, but I believe your correspondent is not “a mile off the mark,” but, on the contrary, has made clearer than before at least one important element in the philosophy of Grapes cracking. I have more than once thought that gardeners were “on the wrong track” when providing an extremely dry atmosphere to prevent the Grapes from splitting—they were, I fear, rather opening the door to the enemy; at least if it is not so I shall be glad to see evidence to the contrary. This phase of a mysterious problem is an important one, and is worthy of consideration and discussion.—A NORTHERN GARDENER.

NOTES AND GLEANINGS.

“AN OLD SUBSCRIBER” says that he was told by a very successful market gardener, that the tubers of JERUSALEM ARTICHOKEs are much improved after taking up by being laid for a time on unslacked lime.

VARIOUS causes were attributed regarding the great scarcity of HOLLY BERRIES last year; this year reasons will be sought accounting for their great abundance. We have rarely if ever seen such a brilliant crop as is now seen on shrubs of nearly all the berry-bearing varieties. Green-leaved and variegated kinds are alike laden with rich clusters. We have observed this in many nurseries and private gardens in widely separated districts, and doubt not that the profusion is general. We have even observed closely clipped Holly hedges, on which berries are seldom seen, studded with scarlet and yellow fruit. In fact we believe that few varieties capable of bearing fruit are this year fruitless. Last year the frosts of spring were generally considered as having rendered fruit trees and Hollies alike barren; but this year different results are forthcoming, for the crops of fruit are sparse, of Holly berries prodigious. How is it?

We have received the annual Report of the MELBOURNE BOTANIC GARDEN, and it is unmistakable evidence of the capability of its Curator, Mr. Guilfoyle. He says—“A number of plants, generally supposed to be unsuited to outdoor culture in this climate were successfully placed out in the grounds. Amongst them were *Quisqualis indica*, *Beaumontia grandiflora*, *Euphorbia splendens*, *Strelitzia augusta*, *S. regina*, *Allamanda nerifolia*, &c. These and many other tropical plants have proved hardy, growing vigorously outside. The *Alsophila excelsa* of Norfolk Island, a Tree Fern which attains the height of 80 feet, has also grown with remarkable rapidity in the open air. As a counterbalance, however, I regret to say that my anticipations respecting the *Cinchona* (Peruvian Bark), have proved correct—it is an unmitigated failure.”

OUR correspondent “A KITCHEN GARDENER,” writes to us as follows on MEDICATED TOBACCO PAPER:—“I had some of this paper sent me a short time ago by Messrs. James Dickson and Sons, “Newton” Nurseries, Chester, to try, and after doing so I must say it is the best fumigating material I ever used. It appears to be made of strong brown paper saturated in tobacco liquor, then rolled firmly up and cut into slices. It is only necessary to place a quantity of it on red hot embers and every particle of it is consumed. There is no half-burning or waste whatever about it, while the smoke from it is efficient in killing the insects and quite harmless to the plants.

It is estimated that nearly 3,000,000 bushels of POTATOES are frequently consumed per year in the States of Maine, New Hampshire, Vermont, and New York in the production of Potato starch. There are about 225 factories engaged in the manufacture of this starch, and the average price paid for Potatoes by starch manufacturers during the past season has been 25 cents per bushel. The aggregate annual production of all the factories is usually from 6000 to 11,000 tons. The value of the total production of Potato starch in the country is from \$800,000 to \$1,200,000 per annum.—(*New York Commercial Bulletin*)

MR. W. PAUL, Nurseries, Waltham Cross, has published his “ROSE ANNUAL FOR 1877-78.” It contains coloured portraits of Red Dragon, Roxy Morn, Perle des Jardins, and Magna Charta; descriptions and relative notes accompany

them. At the end Mr. Paul dwells upon decorative and exhibition Roses, upon Rose shows, and appends letters from correspondents. We add the following as Mr. Paul's selection of worthy Roses:—“Of the novelties introduced in 1875-6, the following have commended themselves most to our judgment—*Hybrid Perpetuals*: Abel Carrière, Avocat Duvivier, Duc de Montpensier, Duchesse de Vallombrosa, Gustave Reville, Jean Liabaud, Madame Ferdinand Jamin, Madame Prosper Langier, Marguerite Brassy, Monseigneur Fournier, Oscar Lamarque, Sultan of Zanzibar, and Triomphe de France. *Tea-scented*: Mdlle. Marie Berton, Maréchal Robert, and Souvenir de Madame Pernet. Of the Roses of the present year (1876-7), the following seem to us the best—*Hybrid Perpetuals*: Mdlle. Emma All, Marie Louise Pernet, and Marquise Adèle de Murinais. *Tea-scented*: Comtesse Riza du Parc, Mdlle. Lazarine Poizeau, Souvenir de Georges Sand, and Triomphe de Milan. We do not describe these varieties, because their full descriptions may be seen in one or other of the leading Rose catalogues, which all lovers of Roses will be sure to possess. Of Roses not yet in commerce, but which will probably be sold in the spring of 1878, May Quennell (Postans), Penelope Mayo (Turner), and Mrs. Laxton (Laxton), have been shown good during the present year.”

A NEW PRODUCT FROM THE PINE.—Vanillin exists in the sap of the Pine (*Pinus sylvestris*) and of the Larch. For the purpose of procuring it the trees are felled during the period when vegetation is most active, and are stripped of their bark. They are then immediately scraped, and the product collected in vessels of tinned iron is immediately heated on the spot to prevent fermentation, filtered, concentrated, and allowed to cool and settle. A substance is thus obtained which resembles powdered sugar, and which is known as coniferin. This is a stable compound, and is sent in barrels to Paris, where the vanillin is extracted. The process of extracting the vanillin is an expensive one, but the product is procured at a less cost than the natural vanilla of commerce can be purchased at.—(*Scientific American*.)

CHRYSANTHEMUMS IN LONDON.

REAL city flowers are Chrysanthemums. They grow and flower on housetops and in cellar-like areas, in small cramped courts and in smoky misty squares, imparting brightness where it is especially required and at a time when it is particularly welcome.

The head-quarters of these city flowers have for years been the gardens of the Middle and Inner Temples, where Mr. Broome laboured so long and so well, where Mr. Dale won renown, and where Mr. Newton practises so worthily. In previous years Chrysanthemum shows have been provided in both the Temple gardens, but for some few seasons Mr. Dale has been fighting hard against encroaching buildings, and at last the buildings have conquered. The veteran retires honoured and respected, and leaves the field open to his younger neighbour. There is, therefore, only one show this year, but that show is a good one, even (considering that all the plants now blooming have been grown almost within a stone's throw from Fleet Street) excellent. There are about four hundred plants arranged on the south border of the enclosure, temporarily covered with glass and screened from the wind by canvas. The flowers are just in beauty and will continue attractive for several days; they will commence fading, however, after the Lord Mayor's day, the 9th inst., and the sooner they are inspected the better.

The exhibition is not remarkable for a few sensational blooms and a greater number of inferior flowers, but it is meritorious by its average quality—its level excellence. That sure index of good culture—rich dark foliage, shows the blooms to great advantage, and renders the display alike creditable to the grower and enjoyable by the visitors. There are no new varieties of striking quality. Gloire de Toulouse, dark rosy purple, and The Cossack, cinnamon scarlet, both Japanese, are the most noticeable. The former will make a good companion plant to the pure and beautiful Elaine, and the latter will be grown for its bright colour. For general decorative purposes the trio—Mrs. George Rundle, white; George Glenny, sulphur; and Mr. Dixon, golden yellow, are still unsurpassed; perhaps, taking all their qualities into consideration, unequalled. Mrs. Parnell may be a trifle larger than Mrs. Rundle, but it is no easy matter to distinguish them. About the same difficulty arises in the case of Plenipo and Katherine Talfourd. The blooms under both these names are good, rosy purple in

colour, and globular in form. The largest bloom of all is Prince Alfred, rosy crimson; but only a shade smaller is White Globe. Refulgence, crimson maroon, is extremely rich, but its yellow eye is objectionable, and it is a question if it can be "grown out," as was at one time supposed. King of Denmark, rosy lilac and golden tips, is distinct and attractive; and Mr. Gladstone and Comte de Ranzeau are very rich. Phidias—the old Phidias—pale rose, is still a favourite; and constant as ever is Aurea Multiflora. The Beverleys, Lord Derby, and Golden Eagle sustain their position as "good old standards." Having smaller reflexed flowers—free, bright, and useful—are Sparkler, Mount Etna, and Bernard Pallisy; they are of the Julie Lagravère type, and are worthy of culture for conservatory decoration and for yielding cut flowers for vases. Amongst the large Anemone-flowered varieties the finest are Lady Margaret (white), which is fine indeed, and Prince of Anemones, lilac bluish.

The Pompons in the exposed border are not yet in beauty, but there is plenty to admire without them; it is encouraging to Mr. Newton to have such a large number of appreciative visitors, and the liberality of the honourable Society of the Inner Temple in providing such an enjoyable display cannot be too warmly commended.

THREE YEARS' EXPERIENCE IN A GREENHOUSE.—No. 3.

HAVING settled down to my work in earnest, I began to consider not only how many distinct varieties of plants I could grow in the one house (I do not mean simply with regard to space), but in what plants I could most excel, the conditions of temperature and ventilation being equal to all, except that I should keep some plants near the stove and others as far from it as possible; indeed, it is astonishing to note the results attendant on the arrangement of a house, whether you place a plant at the back of the door or at the point where the door opens to meet perhaps a temperature of 10° below freezing. For instance, say the door opens on the left, a Stephanotis is close at hand to meet the cutting draught; a Rose is opposite at the back of the door. The Rose will not suffer from the extra warmth, but the Stephanotis will assuredly from the cold. Reverse the positions and both will do well. To obtain successful results these apparently minor points must be studied.

There are many who love flowers superficially, yet amongst the lovers are some whose interest would grow deeper were they only to study a few simple conditions necessary for successful cultivation. It is to the latter section, hoping to increase their number, that my remarks are principally addressed, though I trust to meet with still more congenial spirits—those who love earnestly, not alone the contemplation or possession of a gorgeous flower, but derive pleasure from the germination of a seed, transplant, watch its growth day by day as leaf after leaf appears, and at length the flowers—aye! and what flowers they will be if only tended even with a moderate amount of care and discrimination!

Returning, however, to the practical, I will begin with the arrangement of the house. Say the door facing west opens inwards, on the left are Roses in pots, Acacias, a Plumbago, Azaleas, French Geraniums, Cinerarias, and Ericas; then close to the stove a Gardenia. I had the latter quite a small plant two and a half years ago, and only last month cut from it fifty large flower buds; it having flowered almost incessantly I thought I would give the poor thing a rest. On the right-hand side I place a selection of the same plants aforementioned to bring them on more quickly, also *Pleroma elegans*, *Aloe frutescens*, and the stove plants introduced in the third year of my experience. The two shelves near the glass are valuable for seedlings or cuttings which have been thoroughly started in the bottom heat mentioned in the *Journal of Horticulture*, September 27th. At the east end and back of the stove I arrange a row of Cactuses on a shelf right across, resting on the side lights, and they thrive admirably; but, being placed in such a warm corner I give them a little water in their saucers once a week or perhaps a fortnight. Were they kept in a cool greenhouse this would mean killing them; though after all, depending so entirely as it does on conditions, it is impossible to tell anyone when to water a plant or where to place it, though the latter question is an all-important one, especially in a small house like mine; also whether its requirements are heat, moisture, dryness, sun, shade, &c.; but all these difficulties are soon overcome, and think of the pleasure and satisfaction in surmounting them.

To digress. When leading a bush life in Australia I put my hand to many things, but always found the greatest pleasure was overcoming a difficulty in some occupation of which I had least knowledge. Let no one be discouraged because he has not gained a prize or done well even up to the present; look to the future, and if you only have the subject at heart you must do well.

Now to work. About the 10th of February is the commencement of my year; the birds are beginning to mate, and the hedges are showing their tiny green-tipped buds, and many are the proofs of Nature's returning activity. It is too cold outside to do much, but inside our little house great preparations may be made. Roses, by-the-by, were taken in in January to flower at the end of March and April. Camellias finished flowering are now repotted in partly peat, but as peats differ so greatly I use decayed grass turves with a small handful of charcoal broken roughly about the size of peas, and larger pieces for drainage. Indeed I use charcoal for nearly everything and find it invaluable. See page 139, "Science and Practice of Gardening" (Johnson). This book I have found a treasure. Speaking of drainage, it is an item that must be especially insisted on in pot plants. A plant clogged in the drainage, having extracted its natural food from liquid supplied, the residue of the supply constitutes a poison. This is one point that must never be forgotten.

At the end of February and on into March we begin to strike *Verbenas*, *Lobelia compacta*, *Cupheas*, *Lantanas*, &c., sow seeds in pans or boxes of Golden Feather, *Coreopsis*, and Intermediate Stocks, the latter to bloom in autumn, and many other things required for summer planting and greenhouse decoration. All will grow rapidly on the tray of hot sawdust. Then in April, if you wish to propagate Dahlias, pack your tubers close together in a box with cocoa-nut fibre, place them near the stove, quickly will the shoots spring forth, cut them off close to the tuber, plant in large 60's, they will need nothing more than plenty of water till planting-out time—end of May.

As all things are now growing so quickly, it is of the utmost importance to utilise and economise space. A shelf running full length under a north stage I find answers capitally for all cuttings and seedlings. Place also a couple of rows of these small fry on the ground under this shelf. Everything is now arranged *pro tem.*, and that is all, for allowing plants to remain in one position month after month, or even week after week, is a great error. I arrange my house once a week—it's like taking your children out for a constitutional—for singular as it may appear to those who have not studied the subject, a plant, like a child, requires exercise. Just consider for a moment: the natural atmospheric conditions of all plant life are either heat, cold, moisture, comparative drought, and always more or less wind, or in other words exercise and movement.

Now in a house like mine, where it is necessary to retain heat for *Gardenia*, *Stephanotis*, &c., it is impossible to give the same ventilation you would to an ordinary greenhouse (excepting, of course, in the hottest months in the year). It must not be forgotten that my remarks refer to a mixed house wherein many things are grown, from an *Acacia dealbata*, which will almost stand frost, to a *Gardenia* requiring both top and bottom heat. In this my second year I introduced six *Ericas*, small plants in 60's. I always buy small plants, the pleasure is so much enhanced by growing them on into specimens; you lose all the pride and satisfaction if you obtain them full grown. Then I bought a few *Achimenes*; *Gloxinia tubiflora*, little known, but valuable for cut blooms and general effect; and a *Gardenia*—too much cannot be said of this lovely flower if only generous treatment be given. I introduced also a few Ferns. In selecting Ferns one should choose those widely differing in appearance though still amenable to the same conditions of temperature, &c. In my next paper I will give the names of those I have grown most successfully.—RESPICE FINEM.

KEEPING GRAPES IN BOTTLES OF WATER.

BEING compelled to fill the vineries under my charge with plants, I am cutting the Grapes and placing them in bottles of water. The plan I adopt is that of Mr. Nisbet of Aswarby. It answers admirably, and I wish to recommend it to other gardeners who are situated as I am.—A. N. G.

[Mr. Nisbet's plan and his remarks thereon are appended.—EDS.]

THE Grape-room at Aswarby Park is on the second floor from the ground, with an aspect to the north unvisited by the

sun's rays, and possessing great dryness on account of its elevated position. I find that there are three great evils to be guarded against, and these are damp, frost, and artificial heat. My room is 21 feet long, 16 wide, and 7 feet 6 inches high, with the two outer walls looking respectively towards the north and the east. The walls are thoroughly plastered, as is also the ceiling, the latter three coats deep, and the floor consists of composition. Clean dry sawdust is strewn on the floor, and likewise on the top of the ceiling between the rafters, being intended in the latter case to keep out the frost. Two opening windows look towards the north, and are each fitted on the inside with shutters, which should be closed in severe weather, and the space between them and the window padded with any clean dry material. The door is single, and on the south side, but it can be converted into a double door when required, and the space between closely padded, as in the case of the windows. Thus the room is almost air-tight in frosty weather. All ventilation is effected by means of the door and the windows; and as fresh air, with a good amount of light, is required at all times, I open them whenever the weather permits. Should the day be damp and cloudy, or the wind in the north, I do not open the room, but otherwise I never lose a chance of admitting light and air, if only for half an hour. On the 8th of December, when we had 20° of frost, the temperature in the room did not fall below 38°, and this was without the aid of artificial heat. As a rule, the temperature is nearly 48°, and this can with careful attention be maintained for weeks without artificial means.

At each end of the room are arranged fruit-shelves for the best varieties of dessert Pears and Apples, whilst the centre of the room is devoted to the keeping of Grapes. We have here eight standards, 6½ feet high and 2 inches square, into two sides of which are let, alternately, brackets 1½ inch thick, and which, after being thus fixed, measure 4½ by 3½. Four of these standards are placed on each side of the room, leaving a passage-way all round them. The bottle-receptacles are then laid on the brackets, so as to rest perfectly flat, and are made fast with one screw-nail driven through the under side of the bracket into the under side of the bottle-receptacle. A light facing of wood fitted on the front of the standard rests upon the receptacle and fits under each bracket, thus preventing the receptacle from rising up behind, and giving the whole a neat and finished appearance. Each pair of standards has seven 10-feet lengths of bottle-receptacles, four on one side and three on the other, each length holding eleven bottles, so that each pair of standards carries seventy-seven bottles; it has also an iron spike in the top. There are two laths of wood along the top of the standards, with holes in them at the same distance as that at which the standards are placed, and bound together by means of an iron spike, which passes through the holes. Fig. 69 shows the standard. Fig. 70 shows the top of the bottle-receptacle. Fig. 71 gives a full-sized sectional view of the receptacle containing the bottle.

Fig. 69.

Fig. 70.

I have tried many different mixtures for filling the bottles, but I find there is none equal to charcoal and pure rain water, close to which the stalk of the bunch of Grapes is placed, as shown in fig. 71. The Grapes should be cut as they ripen, and not taken off all at once irrespective of their exact condition. Ten or twelve days before I cut any bunches I went over all the Vines in the Muscat house, trained on the extension system, the foliage of which was at that time perfectly green and healthy. From these I selected from forty to fifty ripe bunches, the shoots of which I shortened to two eyes above the bunch, at the same time letting remain what small laterals there were attached to these eyes. By thus cutting back the shoots ten or twelve days before taking the bunches to the room, the use of sealing-wax or any other material is dispensed

with, as the shoot becomes perfectly hard and dry, and will neither take in nor give off moisture.

I have the bottles prepared beforehand, and after cutting the shoots off at the second eye beneath the bunch, if possible, I carry the bunches, with all the green foliage untouched, to the storing room, and place them in their respective positions. This foliage should be allowed to die-off of its own accord, after which it must be carefully removed.

Fig. 71.

When I have put the first lot past I go to the vinery and make another selection, to come in at the proper time. Although this may seem a slow process to some, I am, nevertheless, perfectly satisfied in my own mind that it answers better in the end. The foliage was nearly all gone from the Lady Downe's when I cut them, but this autumn I intend to select them in the same way as I did the Muscats.

I think the time is not far distant when Grape-rooms will be as common as our fruit-rooms, and answer the end in view just as well, provided they are carefully attended to, for without this Grapes will not keep four or five months.—RICHARD NISBET, *Aswarby Park Gardens, Falmouth.*

P.S.—The bottles are all stoppered with wadding, as in fig. 71.

BEDDING PLANT HOUSE.

WE have received so many inquiries on this subject—that is, a house efficient and economical—that we submit a sectional drawing of a house erected by Mr. Peach, and on which he has written as follows:—

The plant house which I have put up here is economical in point of expense and economical as regards space, all the plants being fully exposed to light. There are two shelves carried all the way round, one of which, the centre shelf, is wide enough

for four rows of 4-inch pots placed crossing each other; the outer one is for three rows of pots. The plants on the shelves are easily watered by a small step-ladder from the central path. I use no putty and have no laps; the glass in the sides (marked c in the section), merely slips into grooves, the upper groove being made seven-eighths of an inch deep, the lower one three-eighths. The glass is slipped up into the upper groove first and allowed to fall into the lower one. The glass for the rafters and sides is all of one size—20 inches by 16, and is 21-oz. fourths. The upright side pieces, 3 inches by 2, which support the upper piece of wood, 3 inches by 3, on which the rafters rest, are set back 1 inch on the wall-plate, so as to allow the glass to slide freely past them in the groove. The glass is continuous on the sides from one end to the other, the

squares merely butting one against the other. This prevents all necessity for sash-bars. I cut a nick in the bottom groove

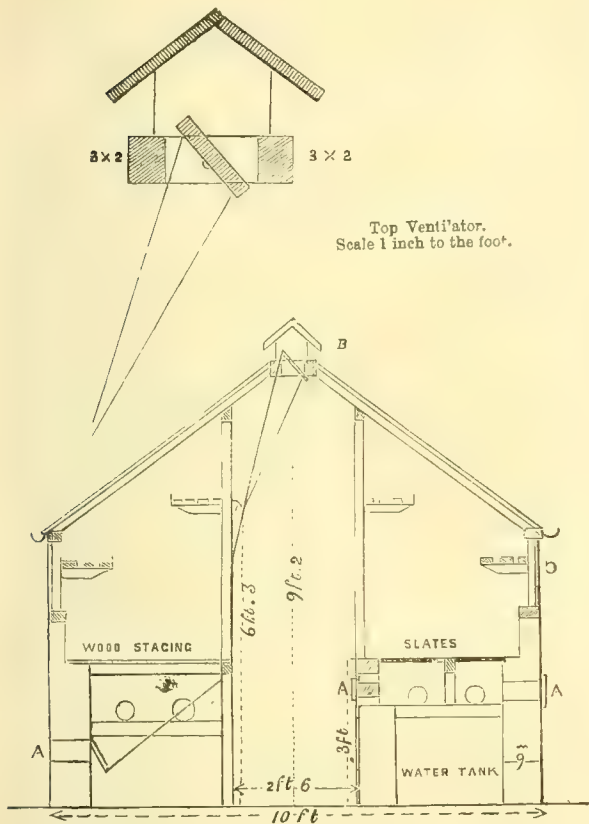

Fig. 72.—Section of House. Scale one-quarter inch to the foot.

in the centre of each pane, to allow rain to drain out of the groove. The panes of glass in the rafters are pushed up from the bottom, and butt one against the other. They are fastened at the bottom by a bent galvanised iron wire pin, which is screwed on the inside of the upper pane 3 by 3, so that at any time in case of fracture the pin can be unscrewed and all the glass taken out. The spouts are fixed in the same way by strong iron crooks bent over to the top pane and screwed on to the inside.

Fig. 73.—Spout.

The water from the roof is carried into a tank made the whole length of one side of the house, by cementing the outer wall, and building an inner wall to carry the staging. The staging over the tank is of slate, with two rows of hot-water pipes confined in the chamber underneath. Sliding ventilators, as A A, are put into the inner and outer walls. If both ventilators are closed, the space over the water tank acts as a hot-air chamber, and keeps the slates at a temperature of from 90° to 100°. The heat is, however, entirely under control by means of the double ventilators.

On the opposite side the staging is open woodwork, laths 3 inches by 1 inch, half an inch apart, and nailed together in 4-foot lengths. Two rows of 4-inch pipes, one flow and one return, are supported by the wooden staging, by wood pieces from the uprights into the wall. These wood pieces are 4 feet apart, and gradually rising 1 inch at every upright from one end of the house till the pipes reach to the highest point of the flow, under the slate tank, on the other side.

The house is 25 feet long, and contains a little over 90 feet of pipe; but the flow is so perfect that there is hardly any perceptible difference between the heat of the flow and return pipes where they enter the house.

The boiler-house is at the opposite side of a path 5 feet wide, at the end and as a continuation of a five-light frame, the flue from the boiler heating the frame; the boiler, a common small saddle-back, properly set, the fire playing through and all round the boiler.

The shelves are made of laths 3 inches by 1 inch, screwed on to light flat iron bars, so as to be moveable in sections, and to be taken out when required; they are supported on wood brackets tenoned into wooden uprights. The water-tank is made with a slight fall to the end farthest from the door; and under the staging, which returns at the end, a small cistern is made, about 2 feet square and 2 feet deep, to dip a can into, the cistern being supplied from the tank by a tap. As there are two rows of hot-water pipes over the water-tank, it helps to keep the rain water during the winter at the temperature of the house.

Fig. 74.—Side c, 1 inch to the foot. Fig. 75.—Section of rafter, 3 by 2 inches. A A, Glass.

Ventilation (A) under the wood staging is through openings in the brick walls, with moveable shutters hung on hinges and regulated by a string. The upper ventilator is a fixed pent with moveable shutters hung on pivots, and also regulated by means of strings. The ventilation is in all respects very efficient, and there is always a slight current of air passing under the glass, as the glass in the rafters does not touch the wall-pan by three-eighths of an inch. This prevents water accumulating on the wall-pan, and any rain which finds its way through the butt joints runs down the inside into the spout, and though there are no laps the house does not leak in the wettest weather. In summer weather the front row of glass can be taken entirely out and Nottingham netting put in its place, or one or two panes can be taken out and the others separated. I frequently do this to harden plants previous to bedding-out.

The house runs east and west, but I should prefer to put it up north and south. I never use any shading, but after the first or second week in April put a slight wash of milk and whitening with a very little paste outside on the south side; this when once dry will resist almost any amount of rain, and breaks the scorching rays of the sun without interfering in any way with the light. I do not claim any particular novelty, but I have never seen any house exactly like it, and I built it for the sake of accommodating as many plants as I could, when potted-off, in a small space.

The house is only, as I stated, 25 feet long and 10 feet wide outside measure, but I can put 2500 Geraniums in 4-inch pots into it. I built it before I had seen any other house without laps to the glass or putty, and I still like the form of rafter better than any other I have seen, as by plunging the groove at an angle and then taking a slight shoulder off with the chisel, a groove is left under the glass, down which any water which is drawn to the rafter runs, instead of dripping into the house. I have never seen any drip whatever from the rafter. I can recommend the house to any amateur who wishes to have a generally useful plant-house, and especially to those gentlemen who expect their gardeners to turn out large quan-

titles of bedding plants, and who have hitherto provided no additional means.

NOVELTIES IN THE ROYAL GARDENS, KEW.

THE Fern collection has of late been largely enriched from several English and foreign sources, and of the new kinds there is nothing likely to be of greater horticultural value than *Adiantum cuneatum* var. *Lawsoni*. It was raised from spores by the Rev. W. L. Lawson of Lynton, who sent the plant to Kew, whence it has been distributed to most of the leading firms, whose representatives have considered it an extremely fine plant, and even by some as superior to *A. gracillimum*. The fronds are lighter, and for some purposes more elegant than those of *A. cuneatum*; the segments are more sharply wedge-shaped and more deeply divided into lobes. It grows with great rapidity, though probably not faster than *A. cuneatum*, the good-keeping properties of which it is found to possess.

Immediately within the door of the Succulent house are two new *Stapelias*. The first is *S. Sarpedon*, a robust-growing kind with fine purple-brown flowers more than 4 inches across and ornamented round the margin by a fringe of hairs; the other is scarcely more than a quarter of an inch across and is elevated on stalks $2\frac{1}{2}$ inches long, by which it is rendered strikingly distinct. Directly the corolla expands the segments are rolled up beneath, so that the flower assumes the form of a little cushion with a depression above and below. The surface appears hoary with a felt of white hairs, though beneath these the colour is brown. It is now flowering for the first time, and a name has not yet been applied. *Paya grandiflora* is flowering in this house and presents a striking appearance. The plant itself is about 7 feet high, and from a single stem below it branches above in several Pine-apple-like crowns of foliage, forming together a magnificent head. Below these are the dried leaves of many past years, clothing the stem as with the shred robe of some savage chief. Two immense panicles are bearing flowers of unusual size in the order *Bromeliaceae*. They are 5 inches in length and of peculiar livid hue. The stems are densely covered with red-brown stellate hairs. A plant of *Crassula rubicunda* is considerably ornamental. It has several stems bearing large corymbs of red flowers, and reaches to scarcely more than a foot high, while having the same width. It flowers with much greater certainty than *Rochea falcata*, and being equal in beauty is desirable in any collection of greenhouse plants.

In the *Begonia* house are suspended near the glass some pots of the new *Torenia Fournieri*, bearing in one case between thirty and forty flowers, thus presenting a very charming appearance. The rare *Impatiens Jerdonia* in the same position has been flowering continuously during the summer, attracting much attention from its peculiar scarlet-and-yellow flowers. *Coffea travancorensis* is flowering profusely in the stove. It is a small-growing species, and this plant, though several years old, is less than 3 feet high; the white flowers are small but very numerous, and the perfume is delicious.

The Orchid collection is enlivened with several fine varieties of *Lælia Perrini*. One dark form in particular is noticeable from its size, substance, and pure colouring. *Cattleya elegans*, in addition to its beauty, emits a sweet perfume perceptible at some distance. Of *C. maxima* there are two forms beautifully veined, the one dark and the other light. A fine specimen of *C. Leopoldi* will shortly be in bloom. *C. Lindleyana* is not as a rule very attractive, though worth mention as one of a splendid genus. *Liparis spatulata*, though without colour, is pleasing to the eye from its gracefully curving flower-spikes in a way similar to *Dendrochilum filiforme*. *Burlingtonia decora* has long been in bloom, and is always welcome with its deep lilac-and-white flowers. *Saccolabium calceolare* is an interesting little plant, the cluster of yellow sweetly-scented flowers nestling low down at the base, and meriting in the form of the lip a well-applied name. *Eria odoratissima*, though not showy, may have mention for its pleasingly scented flowers, produced a few together on a single spike. *Pleione lagenaria* and *P. maculata* are both pretty representatives of the Indian *Crocuseae*. A splendid specimen of *Odontoglossum Bictonenae* is throwing up eleven strong spikes. *O. Uro-Skinneri* and *O. cristatum* are other species in flower. *Oncidium verucosum* has a fine mass of clear yellow flowers, and one plant appears equal to the true *O. Rogersi*. *Masdevallia Veitchi* and *M. gibberosa* flowering together are in strong contrast; the first, as well known, bearing a magnificent flower, while the

other is of the dullest colour and most eccentric structure. *Restrepia antennifera*, to which we have often called attention, and *Gongora odoratissima*, are two very curious plants growing near together. Other ornamental Orchids we find in *Miltonia Clowesi*, *Mesospidium vulcanicum*, and the *Cypripediums* now represented by *C. purpuratum* and *C. Sedeni* as the prettiest in colour. A large plant of *C. Harrisoni* is imposing with several fine glossy flowers. These are accompanied by *C. Roezli* and *C. longifolium*.

STRAY NOTES.

THE roof of our stove is now (October) resplendent with the bright rose flowers of *Passiflora princeps*; the sprays 2 feet and more in length have a telling effect. The individual flowers are of short duration, but the unexpanded buds are very attractive. The flowers are produced most freely from the old wood, the wood requiring to be two or three years old before the flowers are freely produced. It flowers continuously all the year round, being most gay in late summer and spring. Alternating with it we have *Clerodendron Balfourianum*, which never fails to flower in early summer and again in autumn, its branched cymes of creamy white bracts with the peeping star-like corolla have a beautiful effect; indeed, I know not which (the *Passiflora princeps* or this) is the more beautiful. Associated with those on the same roof is *Ipomœa Horsfalliae*, with its great clusters of buds and flowers, successively produced, of the loveliest satiny crimson. It commences flowering in September, and continues through the winter. It flowers from the stem of the old wood like *Passiflora princeps*. *Bougainvillea glabra* gives its mauve-coloured bracts, and these have a very graceful effect when the plant is trained on the roof. The flowering sprays are in higher luxuriance than from plants grown in pots. The four plants named flower early and late, and are remarkable for cleanliness, not having given us the trouble of applying an insecticide for many years. I strongly recommend them for clothing the rafters of a stove. Another plant well worthy of note is *Jasminum Sambac flore-pleno*, which does equally well planted out or grown in pots, and is of the easiest culture. It is very lovely and highly perfumed.

Stove wall-plants are not difficult to find. When the wall is not shaded, or only slightly, none are finer than the fiery scarlet *Euphorbia jacquiniæflora*. Plants in pots afford no idea of the great beauty and usefulness of this plant when planted out in good turfy loam and encouraged during growth with liquid manure. Beautiful as this is it cannot bear comparison with the scarlet-bracted heads of *Poinsettia pulcherrima*. A wall covered with it and the white variety *P. pulcherrima alba*, trained so as to have the floral heads interspersed, has a charming effect. Still more graceful covering for a wall are the *Begonias nitida* and *fuchsoides*, waxy white and the richest of waxy scarlets, the plants growing and flowering all the year round, giving more sprays than any other plants I know. The spray of the scarlet (*fuchsoides*), depending over the edges of an epergne, are inimitable. For a shaded back wall in a stove *Cissus discolor* is admirable, clothing the space as no other plant can with the richest and most lovely of leaf beauty. I may mention that this plant trained to a flat trellis forms one of the richest of live screens for house decoration on "great occasions," having a peculiar richness and lustre, especially its young growths, in artificial light.

Primula intermedia is now throwing up fine trusses of flowers, two and three from a crown; one truss only just clear of the crown is flowering, bright rosy purple in colour, deeper than when the plants flower at their usual time in spring. It was kept in a cold frame in summer, shaded from bright sun, and well supplied with water. It appears to like strong loam and plenty of moisture, but not over the foliage. The truss now flowering showed itself last spring and remained dormant through the summer; this I attribute to the plant being kept too dry and warm during the winter previously. The other trusses will no doubt remain stationary over the winter and bloom strongly, as is not infrequent with *Auriculas*, in spring.

My seedling *Cyclamen persicum*, the seed of which was sown in March and the plants grown in a frame, have done remarkably well, quite as well as I have usually had them from autumn and early spring sowing and growing in heat until midsummer. I have several plants in flower of a very serviceable size for decorative purposes. The old plants have been kept in cold frames and shaded from bright sun. They were kept moist and were not repotted when recommencing growth, but a little of the surface soil was removed and replaced with fresh turfy loam

and cow dung (old), and the result is a great profusion of flower buds and healthy foliage. Some of the corms are 4 to 5 inches in diameter, and promise to flower better than they have done in previous seasons. They will be kept in a temperature of 40° to 45° fire heat and be placed near the glass on a cool moist bottom, for I am convinced that the flower and leaf stems damp at their base from the frequency of the watering necessitated by keeping the plants in a dry place.

The double lilac *Primrose* (*P. altaica*) is flowering very freely in a border among or rather facing some shrubs, the flowers being larger and much deeper in colour than I have observed them in early spring.

Of all the plants used for clothing a wall I have seen none that are at this season more beautiful than the small-leaved *Cotoneaster microphylla*, its deep shining green mantle being so densely and regularly decked with orange-red bead-like berries. *C. buxifolia* is also fine in foliage and berry. Some, however, prefer the bolder foliage of *Escallonia macrantha*, which is very glossy, and the bright rosy flowers are both beautiful and fragrant. The *Escallonia* requires a wall with a south, south-east, or south-west aspect in northerly and elevated situations, but on warm sunny slopes is one of the finest of spreading shrubs. The bright crimson leaves of the Virginian Creepers upon a north wall in contrast with Ivy are very striking. These, with the Traveller's Joy (*Clematis vitalba*) are intermingled. All that is wanted is to cut away the shoots of the *Clematis* close to the Ivy when its leaves commence falling, to expose the green surface during the winter months.

I have been often struck with the great beauty of some plants as we see them in nature. One example will suffice—a Holly standing on a knoll. It may at some time have formed part of a fence. At its base is the common Whin, a mass of gold in spring. Through the head of the Holly peer here and there depending branches of wild Rose, covered in the dog days with blushing buds and pink salvers. The Holly itself, when loaded with its bright scarlet berries (as it is this year), is the finest of all winter ornaments, and always beautiful from its evergreen character.—A YORKSHIRE GARDENER.

MR. RICHARD SMITH'S NURSERY AT ST. JOHN'S, WORCESTER.

PART I.—INTRODUCTION AND ROSE DEPARTMENT.

I HAD long wished to see this great nursery. "It is a marvellous place," said a good judge to me. "You should see it," he added, "you really should; now this September go." Somehow or other I fancied I should never manage to get there; for three autumns I had been invited, but not once had I been able to leave home at the wished-for time. A man with a profession and who sticks to it is not only tied by the leg, but whenever he especially wants to run away it seems to me his leg is sure to be tied the tighter. Then I never wish to be "a peripatetic parson." St. John's Nursery, said I to myself; well, I don't think I shall ever see it. I read the labels on my own trees, "Richard Smith, Worcester." I went to see other people's pyramid Apples and Pears, they had the same labels on. I went to take a baptism for a friend, I saw some new trees being planted in a garden adjoining, trees of ornamental foliage. I saw some little flag-like labels on them, and, while waiting for the little innocent, thought I would see where they came from. There on them the same label, "Richard Smith, St. John's Nurseries, Worcester." I took down by sheer accident (I am not romancing), a copy of the "Florist and Pomologist," it was that for July, 1876, from a friend's shelves, and I opened it at a picture, a coloured one, of the Worcester Pearmain, brought out by Richard Smith, Worcester. Next time I saw a certain Doctor (we all know who that Doctor is) I said, "That picture of the Worcester Pearmain in the 'Florist and Pomologist' of July is an exaggeration as to colour surely?" "Not a bit of it," was the answer, "go to Worcester and see them on the trees." "There," said the Doctor, "there is another picture of the Apple," opening his desk in that old office not far from old Temple Bar, and thrusting a highly-coloured picture in my hand; "there, there it is, correct as possible." Well, seeing is believing, thought I; I will go and see. I will go and see the countless fruit trees, the vast spread of foliage trees, and all the wonders of St. John's. Good reader, I have been to see, and I will take you into my confidence and tell you all I saw. I went one fine day in September, the best time of all the year

perhaps to stroll through a nursery. May is too chilly, July is too hot.

Onward from Wilts to Worcester, on by Great Western, sharp turn up Gloucester way, through the picturesque valley where busy Stroud lies, on further in sight of the Malvern Hills, past innumerable orchards, and Worcester station at last, and there was Mr. Smith, and so we met. 'Tis afternoon and too late to go to work, so my host drives me about the clean bright city, certainly one of the cleanest places I ever saw, and this was a second visit as to Worcester itself. Worcester looks as if it could not have any dirtier merchandise in it than Hops, and china and gloves. The people look clean; the children, those sure tell-tales as to the nature of their parents' employment, look clean. The houses are as a rule red brick with stone facings, and while in some streets half timber houses of the earlier Stuart times are yet to be seen, notably in a street called by contrast or perversity New Street. There is the ancient commandery of the knights, near there the house through which King Charles is supposed to have escaped. Old, very old, this place and others in New Street, but the city has yet on the whole a queen-amidst look, save near the fine Cathedral, when one's imagination goes back for hundreds of years. I am shown the Cathedral, and most beautiful it is; yet it is strange to see, as it were, a new cathedral all bright and new-like inside and out, for the old worn stone is gone and replaced by new. New the reredos, new the gorgeous pulpit, new the fine brass communion rails, new-looking even King John recumbent on his monument, for he is gilt. Beautiful instance and evidences of the generosity of Englishmen of the present era in restoring one of their churches is this Cathedral restored at a vast cost. Very beautiful also for situation is the Worcester Cathedral, standing high and clear, overlooking the broad bright Severn. But the windows are growing dim, and dimmer the light within, for daylight is dying fast, and sight-seeing must be given up perforce.

The next morning to my especial business. Crossing the Severn I am in that transpontine part of Worcester called St. John's, a district chiefly of houses inhabited by those who live by hand labour, not a close quarter happily, but roomy and rural. A mile beyond the river or about, I come to the nursery. This has a history. In the year 1804 Mr. Smith's father began with only a four-acre patch, presently ten more acres were added, and now 167 acres are under cultivation. The great broad drive which we enter is a mile in length, there before you it stretches and runs out like a very high road. The cross drive is seven-eighths of a mile, and altogether there are thirty-two miles of walks. We reach the office, in former days Mr. Smith's residence, but now needed for business—a pretty place, and most unlike the generality of offices where clerks do scribble and accountants tot-up the figures, for it is a creeper-clad villa with fine specimens of ornamental shrubs around.

Mr. Smith, myself, and Cox, the very capable manager of the fruit and Rose departments, proceed on our way. The first things that strike me are the good situation and good climate, the next on inspection the excellent soil so well suited to fruit trees.

As such prominence is given to Roses in our Journal, and out of love for the queen of flowers, I will speak of the Rose quarter first. It consists of 12 acres thickly planted with healthy trees, soon, for the selling time is near, to be scattered all over England. I will dwell upon a few which looked specially well as I stood among them late in September. First there is Dupuy-Jamain, light cherry-red, globular and vigorous, good to bloom, and late. It is a Rose I would greatly recommend for foliage, growth, and flower. This caught my eye very readily. Then second there was Capitaine Christy—a delicate, a very delicate hued Rose, light and fair with deeper centre; a Rose blooming well in autumn. Third there was La France, grand and durable, a friend in need, and it was a Rose a patch of which was always to be seen; not like some Roses, where a patch dies off in the distance from want of size and number of flowers. Fourth the Countess of Oxford, a bright carmine of fine form. Fifth Edward Morren, an English Rose, a crimson bedder. Sixth Comtesse de Serenye, a delicate shaded Rose, which opens well in spite of damp. Seventh Boule de Neige, white and pure, and so truly Camellia-like. Eighth Bessie Johnson, a Rose to which is now attached a tender memory, for the invalid after whom it was named is no longer with us. This Rose was in full glory. It is a very good Rose, and a good late bloomer. As a ninth that caught my eye I would name Mdle. Eugénie Verdier, a beautiful light-coloured Rose,

very beautiful in bud, extremely charming. Tenth I would mention Souperet et Notting, a Perpetual Moss; there are so few good Mosses, and this is very sweet, very double, and one thoroughly to be recommended. Eleventh must come Monsieur Etienne Levet, a fine crimson Rose, as good as possible of its class, and blooming this September grandly. Twelfth, for Sir Garnet Wolesey must be included in the dozen St. John's Nursery Roses that particularly struck my eye; he, the military-named Rose, showed up well. Thirteenth—but hold! I spoke of a dozen picked Roses; but there is such a thing as a "baker's dozen." Go into the first country parsonage you come to, and I warrant you will find "a baker's dozen of curly heads;" so still I say thirteenth Souvenir de Spa, the colour of Eugène Appert, but, unlike that velvety Rose, very full and globular. Such I would give as a short but very charming selection. Of course there were hundreds of others. Reynolds Hole I noticed, perhaps still the best of dark Roses; and President Thiers, a Rose which will help to a recent great statesman's name in our memories.

The Rose quarter at St. John's fairly surprised me, for I did not know that Mr. Smith gave so much attention to that flower, or so much room—12 acres to one flower. One seemed fairly surrounded by an array of Roses of all classes. Some for the Scotch markets, where very high standards are best liked, down to the lowest, the most being worked on the Manetti stock.—WILTSHIRE RECTOR.

THE VEITCH MEMORIAL FUND.

THE Trustees of the Veitch Memorial Fund have not during the past year offered any prizes at horticultural exhibitions, and the consequence is that they find themselves with a considerable balance in their favour, which enables them to make their trust more widely useful, and consequently to keep up greater interest in the memory of Mr. Veitch. They have decided this year to offer ten prizes, consisting of a Veitch commemoration medal and £5 each, to be given at ten provincial exhibitions as follows:—

BELFAST.—For twelve new Roses, cut blooms, sent out since 1873, inclusive.
BRIGHTON.—One bridal and one ball bouquet.
CLAY CROSS.—One dish of Peaches, one ditto Nectarines.
DUBLIN.—Three bunches of Muscat of Alexandria Grapes.
EXETER.—Collection of twelve vegetables, distinct.
HEREFORD.—Twelve new Roses, cut blooms, sent out since 1873, inclusive.
MANCHESTER.—Specimen Orchid.
READING.—Three stove or greenhouse plants.
WOODBIDGE.—Three stove or greenhouse plants.
YORK.—Three bunches of Black Hamburg Grapes.

We highly commend this way of diffusing horticultural interest by means of this excellent fund.

IN THE NORTH.—No. 4. GLASGOW.

THE Botanic Gardens I only hurriedly passed through, but I saw sufficient to make me ask my friend who went through them with me, Cannot the wealthy citizens of Glasgow afford something better in the way of glass? We all know what an excellent Curator they have in Mr. Bullen, but all the curators in the world cannot fight against badly constructed and dilapidated houses. The new nursery grounds of Messrs. J. & W. Thynne in the same suburb (Hillside) show that great care and skill are exercised in the management of the concern. Mr. McCullum, so well known to the frequenters of the Manchester shows, is doing much for it; and as the extension of building is going on considerably in that direction, each year will add to its importance. The houses were full of good plants in excellent health, but it would be needless to particularise where all is well managed.

On my way to Mr. A. B. Stewart at Rawcliffe Lodge I had to pass through Queen's Park, which comprises an elevated position from whence a good view of the city is obtained, and is carefully and tastefully laid out. It is in such places that ribbon bordering, carpet and embossed bedding, and sub-tropical gardening are in place. They give a blaze of colour and make a grand effect. They are in perfection when the people are most likely to frequent them, and the emptiness of the beds in winter and spring is not of so much consequence. One long ribbon border stretching the whole length of the terrace particularly struck me. It was composed of 1, yellow Pansies; 2, dwarf scarlet Tropæolum; 3, white Pansy and variegated Grass; and the centre blue Pansy. Such a ribbon in the south would be a dangerous experiment, but in this cool and

moist climate Pansies and Violas succeed to a degree that would astonish most southerners.

Mr. Stewart is well known as one of the most successful plant exhibitors in Scotland and the north of England, second only to Mr. Shuttleworth of Preston; and therefore one was quite prepared to find under the experienced care of his intelligent gardener Mr. Todd a grand collection of plants, and in this and its varied character I was not disappointed, while every arrangement was made for the well-being of the men employed. There is a capital working shed and an excellent reading room, with a good library of books both for instruction and amusement. There was a very nice collection of the Filmy Ferns, including some rare species of Trichomanes and Hymenophyllum, and some fine specimens of Todea; amongst them were fine specimens of *T. Banerianum*, *T. Luschnanum*, *T. nitidum*, *T. trichoides*, *T. reniforme*, *T. superba* and *pellucida*. Adjoining this was a small house containing some fine healthy specimens of *Nepenthes* and *Ixoras*. In the large Orchid house was a fine collection of Orchids and some choice stove Palms; amongst them *Brahea filamentosa* with its curious white filaments, *Phoenix*, and *Stewartii*. *Oncidium Rogersii* was very fine, as was also *Odontoglossum vexillarium* with six fine growths upon it, giving promise of great beauty. *Bertolonia Van Houttei* was also very fine. The *Azalea* house contained some grand specimens, and *Heaths* were cultivated with great care. Amongst them were some fine plants of *Eriocaulon Mutabilis*, *Shannoni Ventricosa grandiflora* and *Eppsii*, *Massoni*, &c., making one hope for a time when they might once more be in favour. Countess of Haddington *Rhododendron* was also very fine, and so were some of the Tree Ferns. I have seldom seen *Ouvirandra fenestralis* better done; the leaves were broad, and the laticing so very clear and well defined. The *Camellias* were a marvel of good cultivation. The plants were all planted out, and when in full bloom and about four thousand flowers out it must have been a grand sight. In this house was a plant of *Eucalyptus globulus* which had very soon outgrown the place allotted to it. The conservatory was exceedingly well arranged, and one part of it made into an artificial rockery with Ferns planted amongst it was very taking, and a long corridor with a fountain at the end and reflecting glasses was very beautiful. There were no fruit houses, as Mr. Stewart has a lovely place, Ossory Hall in the Isle of Bute, where this is grown, Rawcliffe Lodge being entirely devoted to flowers; and under the able superintendence of Mr. Todd there is no doubt that the good report which it has already obtained as the home of many valuable plants will be fully maintained.—D., Deal.

NEW BOOK.

The Fern World. By FRANCIS GEORGE HEATH. London: Sampson Low & Co., 188, Fleet Street.

ENCOURAGED by the success of smaller works on Ferns, "The Fern Paradise," and "A Plea for the Culture of Ferns," the author has produced the present volume. He has chosen a comprehensive title, and has written an agreeable book. His subject is popularly treated, the object, as stated, having been to "inculcate a love for the study of Nature." The volume contains chapters on Fern-hunting, descriptions of "Fern Land," with notes on the distribution and culture of British Ferns. It is illustrated with views of Fern-scenes in Devonshire, and the more familiar species of hardy Ferns are represented by coloured figures, which are sufficiently well executed to be recognisable. Here we observe a serious mistake: The letterpress facing plate 3 would convey the impression that the Royal Fern and Hay-scented Buckler Fern are there represented; No. 1, however, on the plate is *Athyrium Filix-femina*, and No. 2 *Lastrea Filix-mas*. An extract from the chapter on Fern-collecting will sufficiently show the nature of the work.

"Ferns may be freely taken up at any time. Where a Fern-collecting tour is decided on the collector should be provided with a small garden fork, a stout chisel, a hammer, a strong clasp knife, a trowel, and a covered basket made either of rush or wicker, or other receptacle for carrying the Ferns. Nothing so much promotes the rapid recovery of a plant after removal as the exercise of great care in getting up the entire mass of roots and rootlets. It must be remembered that it has often taken the rootstock a long time to develop its network of rootlets, which as they grew have penetrated into all the surrounding interstices of the soil or rock from which the plant derives its sustenance. If, therefore, the work of months is ruthlessly undone in a moment by the thoughtless tearing-up of the plant without its mass of root-feeders, it cannot be expected

that the same vigour will be immediately shown under cultivation as was before exhibited.

"It is especially in the removal of the rock-loving Ferns that the greatest violence is usually done to the plants. Most of the rock-growing species have very abundant, wiry, fibrous rootlets, which penetrate in a very remarkable way the stony interstices in the neighbourhood of the rootstock. It is often made a subject of complaint by Fern-collectors that the rock-growing species are more difficult than any others to establish under cultivation. But the difficulty arises chiefly from the circumstance which has already been alluded to. No doubt it is often a matter of difficulty to uproot the rock-loving Ferns, and it is for this work that a hammer and chisel are necessary, so that by the careful undermining and removal of the adjacent portions of rock the crown, rootstock, and rootlets of the specimen desired may be got out unharmed.

"Where by the careful process recommended Ferns are got out from their places of growth, damp moss or other moist material should be wrapped securely round their rootstocks and rootlets. In this way they can be conveniently carried to a considerable distance without any covering to the fronds, although if the air be very hot, dry, and sultry the fronds, if intended to remain on the plant, must, especially those of the most fragile or herbaceous kinds, be kept under shelter, as they would be if put into a covered basket or other convenient covered receptacle. In removing the larger kinds of Ferns, however, during the summer it may often be found convenient, especially where room for putting the specimens has to be economised, to cut off all, or at least the largest of the fronds, and to wrap in moss, or keep covered merely, the rootstocks and rootlets. When planted in the garden or other place of cultivation new fronds, as we have already said, will, if under favourable conditions, speedily be thrown up to supply the place of those removed. Where a tour is made in search of small specimens of Ferns it is best, after wrapping moss (which is generally to be found in the neighbourhood of Ferns) around each little root, to pack together, root side by side with root, the whole of the specimens. If a moist wrapper be then placed round them they will keep fresh for days, and even for weeks if occasionally looked at and sprinkled with water. If a quantity of reed straw be taken with the collector on a Fern-hunting excursion it will be possible to preserve the fronds of the larger species by putting the reeds on the ground in a line with the direction of the fronds, and rolling them round the mass of roots and tying them in that position. In this way the tops of the reeds standing out around the fronds will protect them from injury until they are safely disposed of in the garden at home. In collecting the rock-loving species of Ferns it is desirable when possible to detach a little portion of the rock, so as to avoid tearing off the rootlets of the plant.

"One important object in Fern collecting should always be kept in mind. Before removing a plant from its home, the soil in which it is growing, its positions as to shade or shelter, and the manner in which it has fastened itself to sloping bank, to tree fork, or to rifted rock, should be carefully noted; and the cultivator should then endeavour as nearly as possible to provide similar conditions of growth under cultivation. In this way many curious and beautiful lessons will be learned from the teachings of Nature."

FORCING SEAKALE.

VARIOUS modes of forcing Seakale are adopted, but the method I wish briefly to point out is the simplest, cheapest, and best I have found.

In the first place the ground is measured out in 5-foot beds with 2-foot spaces between the beds to form alleys, the soil is taken from these spaces 18 inches or 2 feet in depth and thrown on each side to form the beds, which are made firm at the sides with the spade to keep them from crumbling down. The beds are made level, and are then ready for the insertion of the roots. A trench or drill is chopped out at one end of the bed; the plants are placed in the trench about 2 inches apart and 6 inches from row to row, leaving 6 inches on each side of the bed. After enough has been planted for a batch fill the trenches with well-heated manure (which should be prepared beforehand) and treading it rather firmly into them. The beds will then be ready for covering over, which is done by bending bean or hurdle rods over the beds, placing the thick end on the outside of the bed, or rather into the trench, and tying the thin ends together to form an arch about 3 feet high. A covering of mats is then tied over the hoops; sometimes two or three coverings are used according to the weather. In very severe weather, or when the Kale is wanted quickly, a lot of long manure is used between the mats, the outside mats being secured to pegs driven into the sides of the beds to prevent the wind blowing the mats off; they are also tied to each other on the top.

By this treatment Seakale can be obtained in a month or five weeks. If too much is likely to be produced at once, or if it is required to keep some back, take off some of the covering, which will also improve the flavour of the Kale. It never tastes so earthy when grown in this way as when large quantities of manure and leaves are carted together to grow a few dozen heads quickly and too often poor and spindly.—J. P.

OUR BORDER FLOWERS—CROWFOOTS.

AMONGST the most beautiful of our border and spring garden plants are the Hepaticas. In years gone by they were classed with the Anemones, but now form a family of themselves that may be said to be always bright in sunshine or in shade—indeed, all the more beautiful in partial shade.

We are indebted to North America for these charming spring beauties. They are well adapted for all purposes that flowers and plants are required, for they are a very accommodating race. They are everybody's flower. Place them where you may—in pot, basket, rock or border, indoors or out—they afford us a pleasure that no other flowers can in the sunny days of spring. Then they are among the old, old border flowers, and planted in masses or in lines, alternating their colours, the effect is charming. Being evergreen they may remain as permanent plants, or be removed to make room for the summer occupants of the garden.

Of Hepatica the single kinds are increased by seed and division. The seed is best sown as soon as ripe in well-drained pots in a mixture of sandy loam and peat in a cool moist pit or frame. Patience will require to be exercised, for the young plants may not make their appearance until the following spring. They will require care in watering. When large enough they can be pricked out in pans or boxes as most convenient, affording a little shade in bright weather until established. The double varieties are increased by division in the autumn, that they may be ready for their work in the spring. They are rather impatient of removal, and are better when left where raised. They like a free soil, moderately rich; all the better if gritty. They should have efficient drainage. To see these plants where they are grown by the thousand for sale is a sight never to be forgotten.

The kinds most common in cultivation are the single blue and white, double blue and red. *Hepatica angulosa*, the largest of the race, is a most telling plant for all purposes, and is worthy of very extensive cultivation. It is to be regretted that we have not more variety in colours of these old favourite plants.—VERITAS.

FORK AND HOE.

THE benefits accruing from the liberal use of these tools are generally underrated. The primary use of the hoe is to uproot and destroy weeds. Its secondary use is to keep in moisture and admit the heat of the sun and air. A hard close soil dries much quicker, and is not so easily moistened either by irrigation or by rain. Plants grown in soil which is in a close and hard state always suffer from drought sooner than plants which are grown with a surface kept loose by hoeing. The reason of this is, that a compact surface evaporates moisture drawn from beneath by the force of capillary attraction less readily if there is some loose material on the surface. Everyone knows that litter or short grass strewn over a piece of ground will be the means of keeping that ground in a moist state, while an uncovered piece will be parched and dry during a long drought. A surface of loose soil acts in the same way, only less effectually. A well-hoed piece of ground admits the sun's rays more readily than an unhoed piece. This may be proved by the use of a thermometer. After heavy rain has battered the soil until it is quite smooth, and cracks on the surface after the rain is gone and the sun comes out, hoe a piece of ground which is exposed to the sun, insert a thermometer in it to the depth of 8 or 10 inches, insert one in an unhoed piece, and after the lapse of twenty-four hours examine the two thermometers, and you will have convincing proof that a loose surface favours the absorption of heat. The advantage of warmth in the soil we may pass over without remark, as almost anyone can tell whether plants thrive better in a warm or cold soil. I may remark, however, that a fresh surface in pots acts in the same way, and that a clean pot absorbs heat more readily than one covered with slimy matter, and at the same time retains it better.

Forking the soil has the effect of drying it in wet seasons

and of keeping it moister in dry ones. A soil deeply dug and well broken with the fork allows the free passage of water; and everybody knows, or should know, that a wet soil is a cold soil, and oftentimes sour to the bargain; and plants do not thrive in a cold sour soil. And though it may seem a paradox, a deeply-dug well-forked soil is always moister in a dry summer. When deep and loose, soil has the property of drawing water from the subsoil to a greater extent than when in a hard unpulverised state, and, as pointed out, retains it to a great extent if there is a loose upper layer.

A well-forked soil prepares the manurial matter in the soil much more rapidly than a hard solid one. It admits water more readily to dissolve the saline matters in the soil, and so enables the plants to absorb them. Pulverised soil admits air more readily, and it is only by the decay of manure that it is fit for food; and it is only when brought into contact with the air that it decays. Decay, in the case of ordinary manure, means that the substance is being converted into ammonia, carbonic acid, and the various salts, which may be called the foundation of the plant. These gases—ammonia and carbonic acid—are soluble in water, and pass into the system of the plant through the roots in this state. The roots also possess the property of taking in the gases without the medium of water; but if the air be not admitted freely the supply of these gases will be limited, as their formation at all depends on the presence of atmospheric air. While these gases are being formed the saline matter of the manure is set free, and so forking the soil tends to produce a free growth by indirectly furnishing the plant with food. Thus by causing a greater growth in the case of vegetables grown for their leaves an improvement of the quality is the result, to say nothing of the quantity. This greater growth causes greater succulency in such things as Spinach, Lettuce, &c. Forking the soil improves Potatoes very much. It does so in being the cause in wet seasons of drying the soil, rendering it warmer, &c., and we know that these conditions favour the production of Potatoes superior in quality to those grown on cold wet soils. I have seen Potatoes of fine quality dug from heavy soil, but which had been well pulverised, and wet waxy ones when the soil was left close and firm. Unless clay soil is well worked with prong and hoe good Potatoes are seldom produced.

The production of mealy Potatoes is greatly favoured by the use of the fork for another reason: a loose soil which admits the air freely encourages the production of carbonic acid gas. Now we know that the roots of plants take up this, and that it is decomposed in the leaves and rebuilt into a new compound or compounds. One of these compounds is starch. It is well known that the difference between mealy Potatoes and wet ones consists in the amount of starch contained in the cells of the Potato tuber. In the case of a mealy Potato, when viewed through a microscope, the cells are packed full of starch granules, while in the case of a waxy one these cells are full of water, and the starch granules are not nearly so abundant. When a Potato of this description is boiled the granules dissolve in the water and the Potatoes are waxy. In the other case the cells do not contain water enough to dissolve the starch granules, and so when cooked they assume the character of flourballs. Such are a few of the advantages of the free use of prong and hoe. It may be said that a full knowledge of their use, and that knowledge applied, constitutes good gardening, for the principles involved are applicable where the fork and hoe would be out of place.—ONE WHO HAS WHISTLED AT THE SPADE (in *The Gardener*).

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

KITCHEN GARDEN.

DURING the last week our time has been taken up with digging and trenching, also clearing away the fallen leaves from the walks and borders. The rains have made the walks sufficiently moist to enable us to clear off any weeds which have grown through the gravel. This ought always to be done before sweeping the paths, as it is generally necessary to draw the broom over the gravel even if a few weeds only have been pulled out. When the gravel is nearly dry the roller may be passed over it.

It is a good plan to have all the quarters and borders trenched or dug as early as possible, so that the ground may lie open to all the frosts of winter, and at any time that the surface is dry it may be lightly forked over. Besides pulverising the soil this exposes the larvæ of insects, &c., to the influence of frost and to the sharp eyes of birds. One remark is necessary here in

passing, and that is not to dig or trench when the ground is saturated with wet or when it is raining. We know a place where men are sent to trenching when it is too wet to do other work, and we have known men cutting the frozen ground with pickaxes and turning it over into the trench with a crowbar. A little forethought might alter this state of matters. In most large places work may be found for the men under glass or in the potting sheds.

We have previously written of earthing-up Celery and the manner of doing it. Those who have not yet earthed-up their main crops ought to do so at the earliest opportunity. The leaves and earthing-up material ought to be quite dry. We have known peat soil used to earth-up Celery, and it has answered well: this hint may be useful to those who have plenty of sittings of dry peat from the potting shed. Whatever is used in earthing-up ought to be prevented from falling into the heart of the plants.

When cold frames can be spared a quantity of Lettuce plants ready for use may be planted very thickly in them, so that they may be protected both from wet and frost. The lights should be removed during fine days and be tilted at the back on fine nights. We have advised covering Endive with boards, but as the season advances the plants suffer from frost and wet. Those who possess a dark cellar can blanch Endive very well. Lift the plants carefully with balls of earth and plant them closely together. This plan has also the advantage of the Endive being easily obtained when it is wanted. Should Lettuce and Endive be scarce Chicory roots will be plentiful if a few rows were sown about the end of May. The roots may be potted closely together in 10 and 11-inch pots. They will grow in any dark place in a temperature of 50° or 55°. The leaves should be a yellowish white when cut, and ought not to exceed 6 inches in length. The soil in the pots must not be allowed to become dry, else the produce will be tough. We have cut down the Asparagus, and carried away the stems where they will not again be brought back to the garden. They are densely covered with red berries containing seeds, which only require to come in contact with the earth to vegetate freely. The weeds have been removed from the beds, and decayed leaves have also been picked from Brussels Sprouts.

VINERIES.

We have not been doing much in this department except preparing the early houses for forcing and seeing that no decayed berries are allowed to remain on the bunches. We are constantly being asked about lifting Vines, either to transplant them to a new position or for the purpose of renewing the border entirely. Instructions for renewing the border were given two weeks ago. Lifting the Vines entirely is another thing, and we do not advocate this practice. It is seldom necessary to lift young Vines, and it will not answer to remove very old ones. If young one-year-old Vines are well managed they will in nine cases out of ten give the greatest satisfaction. We have planted Vines from small pots in March and trained up on the base of the cane from two to six shoots, and each of them has run up to the top of a rafter about 20 feet long the same season. A dozen moderate-sized bunches of Grapes could be taken from such a Vine the following season, and it would improve annually, whereas an old Vine, if the roots are entirely lifted out of the ground, would not show such rapid improvement. Those who are intending to purchase young Vines for planting will have their minds exercised as to the best varieties to plant. Were we confined to three varieties—and many persons do not care for more than this—they would be Black Hamburgh, Muscat of Alexandria, and Lady Downe's Seedling. Of course there are many other varieties, each having valuable distinctive qualities of their own, that ought to be in all large collections, and the Muscat of Alexandria requires a higher temperature than many persons can give it. If a high temperature could not be obtained some other white sorts would have to be included. Our choice is for Buckland Sweetwater, but it is right to say that many of our best gardeners prefer Foster's White Seedling. Dr. Hogg, raised by the late Mr. Pearson of Chilwell, is by far the best round white-berried sort with Frontignan flavour. In flavour it is not surpassed by any, and it is superior to all others of its class in bunch and berry. The vexed question as to whether Venn's Black Muscat or Black Muscat of Alexandria (Snow's Black Muscat) are distinct sorts has not yet been decided. We saw the two growing together at Chiswick the other day, and for all practical purposes they were alike. If there was any difference between them it was that the new sort was more badly shanked than the other. Alicante is a good late sort, and Clive House Seedling will probably be equal if not superior to it when it is better known. Those intending to plant should now select moderately strong well-ripened canes struck from eyes this year.

CUCUMBER HOUSE.

Strong plants were planted out two or three weeks ago in place of the old ones, which were destroyed. We would have planted earlier if another house had been available, as it is not easy to keep up a continuous supply if the old plants have to be removed from a house to make room for those that are to

follow. The only plan is to grow the young plants to a good size, shifting them on so that they may not be root-bound. We like the soil to be in the bed long enough to be well warmed, and the plants are put out without disturbing the roots. It is also an advantage to have the surface of the bed mulched with decayed stable manure; the spent dung from a Mushroom bed is as good as anything. Before planting them out we had the woodwork and glass thoroughly well washed. It is not possible to have too much light for Cucumbers. Insect pests must be kept from the leaves.

PLANT STOVE AND ORCHID HOUSES.

In this department plants are now pretty well at a standstill, at least hardwood subjects, such as *Ixoras*, *Dipladenias*, *Allamandas*, that are intended for summer flowering. It is not to be supposed that such plants flower only in the summer, as by a little management they may be had all the year round. With a dozen plants of *Ixora* of different sizes and species we have had trusses of bloom in every month of the year. It is merely a matter of heat and watering. At present we have three or four species of *Ixora* in flower, including *I. javanica*, *Colei*, and *Williamsii*; also *Dipladenia amabilis* and *Allamanda Schottii*. Should such plants be required to flower in June and July the temperature of the house should be now kept about 60° at night as a minimum with a rather dry atmosphere, and the plants to have water at the roots if they are likely to suffer. From the beginning to the end of January the plants should be pruned and be started in a temperature of 65° or 70°, and this should be increased as the season advances to 70° or even 75° at night. All plants that are showing flower or growing should be as near the glass as possible. Flowers are not only higher coloured but they last longer if they are allowed to open in juxtaposition to the glass, and the young growths formed close to it are the most satisfactory.

Orchids in all the houses are enjoying a season of rest. At this time of the year there is much danger of unduly exciting them into growth. Those requiring an East India temperature, such as the different species of *Aërides*, *Saccolabiums*, *Vandas*, and *Phalenopsis*, do best when the sphagnum is kept in a growing condition on the surface of the pots; and as the time has now come when water must be withheld to a certain extent, the moss is apt to die. Our plan is just to give sufficient water on the surface to keep the sphagnum alive, taking care that the water does not go deep into the compost. *Cattleyas*, *Lælias*, &c., at this season may go for two or three weeks at a time without water if they are in pots; when on blocks they require water almost daily. *Dendrobium nobile* for summer flowering has been placed in a greenhouse temperature. Other species from warmer climates are also at rest, the East Indian species in a temperature of about 55°. The cool house has also been reduced in temperature; it is now about 45° to 50° at night. Here *Masdevallias*, *Odontoglossums* of an alpine character, and the Mexican *Oncidiums*, such as *O. macranthum*, flourish in the moist cool atmosphere, and they seem about right when the leaves are fringed with dewdrops glancing in the morning light. Now is the time to eradicate all insect pests. It is dangerous to fumigate for the destruction of green fly and thrips; but if the houses are lightly fumigated for three nights in succession, supplementary to washing the leaves with soapy water, these pests will be disposed of. Wash all plants infested with scale and mealy bug.—J. DOUGLAS.

TRADE CATALOGUES RECEIVED.

E. G. Henderson & Son, Pine-Apple Nursery, Maida Vale, Edgware Road, London, W.—*Catalogue of Fruits and Roses, Shrubs and Hardy Climbers.*

Richard Bradley, Halam, Southwell, Notts.—*Catalogue of English-grown Camellias, Rhododendrons, Forest and Fruit Trees, &c.*

J. J. Van Loghem, Haarlem, Holland.—*Wholesale Price List of Dutch Flower Roots.*

André Leroy, à Angers (Maine et Loire), France.—*Catalogues of Fruit Trees, Seeds, Bulbs, and Plants.*

Hogg & Robertson, 22, Mary Street, Dublin.—*Catalogue of Fruit and Forest Trees, Conifers, Evergreens, Roses, &c.*

Eugène Verdier fils aîné, 37, Rue Clisson, Gare d'Ivry, Paris.—*Descriptive List of New Roses.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three

questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

POOR PEOPLE'S GARDENING (*A. L. B.*).—If you will prepare a little pamphlet and have it printed we will publish it.

BULBS (*R. W. N. F.*).—Our "Greenhouse for the Many," price 9d., contains full directions for their culture.

ORCHARD HOUSE (*J. C. G.*).—You can have Mr. Pearson's book on "The Orchard House" if you enclose twenty postage stamps with your address. The sized house you mention would be small. Dwarf-trained trees require much attention, and, of course, bear less fruit than larger trees.

TREATMENT OF STOVE AND GREENHOUSE PLANTS (*Amateur*).—The treatment of most of the plants you name have been given in previous numbers of the Journal. *Fuchsias* would not be safe in a cold frame during the winter, but the tuberous-rooted *Begonias* would if the pots were plunged. *Lilium auratum* would do well plunged in a sheltered place out of doors. But you want so much information that it would be best to obtain the manuals published at this office on the subjects.

TREATMENT OF ROSES IN POTS (*A. W. H.*).—They ought to be pruned according to the time they are wanted to flower. If you want them to flower early you must prune early. If they are to flower late, say in the early part of June, prune about the end of February. It is not wise to prune them immediately they are potted, better to wait a week or two until fresh roots are formed. You may dig Roses up from the open ground now and pot them. Water the pots in winter just sufficient to prevent the soil becoming dusty dry, and when the plants commence growing in the spring gradually increase the quantity. Roses out of doors may also be moved any time this month.

BOTTOM HEAT FOR CUCUMBERS (*R.*).—We fancy the water does not circulate very freely in the pipes, else the flags would be sufficiently warmed to heat the compost. Our beds, in which the plants bear freely all the year round, have a foundation of bricks over two 8-inch pipes. They give us a bottom heat of about 85°.

HYACINTHS IN GLASSES—ROSES FAILING (*R. N.*).—Two or three lumps of charcoal keep the water pure in the glasses. A fourth part of decayed cow manure should be added to the soil for *Hyacinths* in pots. Roses on their own roots or budded on the seedling Briar would do better than standards in your soil. You should get the most robust varieties of Hybrid Perpetuals. The best time to prune *Rhododendrons* is in March, but they will not do well if you cut them back to the old wood.

PLANTING VINES (*Civil Servant*).—We have sometimes found that old Vines do not transplant well, and in many cases it is better to plant young ones. Your Vine may not be very old, and you may be able to lift it with a large portion of fibrous roots attached; in that case you might try it again. Transplant it at once. For a house like yours plant only Black Hamburgh; but if you want a white, Foster's White Seedling is the best. We have not tried the heating apparatus of which you enclose a drawing, but rather like its appearance. It is dangerous practice to have the fire inside the house. The cheapest way for you would be to build a flue through the house, carrying it along the front and round the back.

HARTLEY'S PATENT GLASS FOR GREENHOUSE (*Subscriber*).—We would prefer the clear glass for some districts; but as you have proof that plants can be grown well under the patent glass, and as shading may be dispensed with, why not try it?

TREATMENT OF THE SEEDLING BRIAR (*Seybor*).—Sow the hews either in autumn or spring in light friable soil; it need not be very rich. Some of the seeds will vegetate the following summer, and some the next season. The plants will be small the first year—you may grasp two hundred of them in one hand. If these are planted out in November they may be budded the following autumn close to the ground. As you have been unfortunate you might purchase a few hundreds; they are sold at 1s. 6d. per hundred.

SOLANUM CAPSICASTRUM BERRIES POISONOUS (*Subscriber*).—Although perhaps not positively deleterious, we should yet be inclined to regard them with suspicion. Dr. Hogg in his "Vegetable Kingdom," page 551, states—"The fruit of *S. pseudo-capsicum* has been supposed to be deleterious, but M. Duval says they are not so, for a dog which swallowed thirty of them, out in pieces, sustained no injury." This is a near ally of the *S. Capsicastrum*, and whether the berries are poisonous or not, their taste is such as not to recommend their use. Be cautious.

PRUNING SHRUBS (*M. S. Bowen*).—Now is the time to cut down old Laurels and shrubs of a kindred nature. You may cut Laurels and Holly down to the ground, and they will throw up young growth next season as plentifully and vigorously as an Ash or Chestnut. *Laurustinus* if healthy bears pruning well, and is improved by it. Your old Roses may be pruned now or upon any suitable weather during winter. Your *Cyclamen* is *C. hederifolium*, a native of Europe, growing abundantly near the shores of the Mediterranean. It is perfectly hardy, and the tuber under favourable circumstances is sometimes a foot in diameter, the leaves being then much larger than those you sent us.

CUTTING OFF LARGE LIMBS FROM OLD TREES (*South Devon*).—It is never advisable to cut off large branches unless they become broken and are likely to decay. The best treatment for your Elm, which has suffered so severely in the late storm, is to cut all the stumps clean off close in to the stem, and to give the wound an immediate dressing of hot glowing mastic, and taking due precaution to have it thoroughly covered so as to exclude air, and thus afford the best possible chance for the wound to heal. No harm is likely to arise from branches broken asunder at some distance from the bole, all such being likely to put forth new growth next season, and you may safely consult your own taste as to retaining them. The best mastic for the purpose consists of 1 lb. of Burgundy pitch, 4 ozs. of black pitch, 2 ozs. of yellow wax, 2 ozs. of rosin, 2 drachms of mutton suet, all thrown together in an iron pot melted over a fire and applied hot with an ordinary paint brush.

MAIDENHAIR FERN (*W. H.*).—The old fronds should be cut off as they fade, but we prefer leaving them on for a time to shelter the young growth when the plants are exposed to the strong light of a plant house. In a shaded fernery such shelter is, of course, unnecessary. The Fern you send is *Pteris serrulata*.

YEW HEDGE (*Tyro*).—As you trenched the ground and enriched it when you planted the hedge two years ago, it can hardly require a surface-dressing yet. A mulching of manure would, however, serve to attract the roots into the best soil near the surface, and check excessive evaporation of moisture in summer, and so prevent injury from drought. Plant nothing within a couple

of yards of the hedge, and see that the roots of neighbouring trees or shrubs do not steal into the enriched soil and impoverish it.

TAXONIA VAN-VOIXEMI SHEDDING ITS FLOWER BUDS (L. P.).—Look to the roots; they have either been kept too dry or too wet, most probably the latter, as the foliage and growth is healthy. When growth ceases and the plant is at rest trace out as many roots as you can, lift them, remove all the old soil and replant in a mixture of loam that is naturally very fertile or made so with old hotbed manure. Powdered charcoal, mortar rubbish, broken bricks, and road scrapings—anything in fact that will make a free, rich, sweet, open soil. Beneath this place 6 inches of broken stone or brick with a 2-inch drain-pipe continued to the nearest outlet, so as to render any subsequent accumulation of stagnant water impossible. Thin-out and shorten the branches, and next season you will have plenty of blossom.

COAL ASHES FOR HEAVY SOIL (Idem).—The gardener who told you that coal ashes would "poison the soil" is mistaken. Put on all you can obtain, and use no sand. Drainage, plenty of manure, and heavy dressings of coal ashes with frequent stirring is the very best treatment for all soil of a close heavy texture. It is by such simple means that we have converted a comparatively barren soil into a high degree of fertility and productiveness. If you have not already made drains now is the best time for the work; make them of 2-inch pipes 4 feet deep and 30 feet apart, with 4-inch main drain.

GLOXINIAS UNHEALTHY (A Young Beginner).—A soil formed of peat and sand with a little loam is wrong, and is probably the cause of your failure. Use two parts of rich old manure and one part each of turfy loam, peat, and sand. Mix this thoroughly but do not sift it, rather leave it in a rough condition with plenty of pieces of an inch in diameter. Use broken tiles freely for drainage, press the soil firmly about the tubers, attend well to watering, always having the water of the same temperature as that of the house in which the plants are growing, and when the flower buds appear give weak cowdung water regularly. Gloxinias never answer better than when grown under the shade of Vines, and your brown foliage may in some measure be attributable to exposure to the full glare of the sun, or to the attacks of thrips or red spider.

SOIL FOR GARDENIAS (Idem).—These plants answer well in soil consisting of a mixture of sandy peat and leaf soil, or old hotbed manure. After the flowers fade the plants are taken from the conservatory into pits, where they remain till the repotting takes place, which is usually about a fortnight before placing them in heat; then plunge them in a mild bottom heat, gradually increasing it as the plants make growth. As the earliest batches come into flower they are taken to the stove, and when their flowers fade the plants must, of course, be gradually hardened before being taken back to the pit.

CLEODENDRON BALTICUM (Idem).—To flower in July, the plant now in bloom should be kept somewhat dry after the flowers fade. Early in February prune away as much of the spent growth as you can, shortening and thinning the remainder. Syringe regularly, give more water to the roots, keeping the plants in a steady temperature of 65° to 70°. Just as the young growth appears shake out and repot in soil of two parts old hotbed manure, two parts turfy loam, and a fair admixture of sand and powdered charcoal. Take especial care about drainage, 2 inches of broken crocks is not too much. After repotting do not overwater, but when the shoots are a few inches long the roots will be pushing freely into the fresh soil; then water copiously and encourage a free strong growth till May, when less water must be given to give a check to the growth and induce the formation of flower buds, which should make their appearance abundantly by the beginning of June.

PAINT PERISHING (J. F. K.).—We can quite sympathise with you, it almost seems like labour in vain to paint a plant stove, exposed as the roof is to the cold of winter and heat of summer. We know nothing to prevent the paint from perishing. If something could be invented it ought to be a fortune to the discoverer.

PRESERVING LATE GRAPES AFTER BEING CUT (H. Borland).—We cut all our Lady Downe's Grapes about Christmas. The bunches are cut with as long a stem as possible. The stem is then inserted in a bottle of clear water kept sweet by a few lumps of charcoal. The bottles are suspended in a sloping position so that the bunch hangs clear of the bottle. They must be kept in a dry room from which frost is excluded. We have kept them good in this way until the end of May, a period of five months.

HEATING A SMALL GREENHOUSE (W.).—The plants you name would not be injured if the thermometer fell occasionally to the freezing point. Any of the small stoves advertised in this Journal would answer to heat it.

LIST OF PEACHES AND NECTARINES (J. E.).—The best selection would be three trees of Hale's Early, two of Royal George, two of Noblesse, two of Walburton Admirable, one of Princess of Wales, one of Alexandra Noblesse, two of Dr. Hogg, and two of Early Louise. The best Nectarines in your list are Stanwick, Elrage, Fine Apple, Large Elrage, and Victoria.

WHITE FUNGUS IN MANURE (Manx Cat).—We cannot tell whence the spores come which produce the fungus. Quicklime or common salt mixed with the manure might prevent its appearance.

NAMES OF FRUITS (T. S. G.).—1, Norfolk Beefing; 2, Dumelow's Seedling; 3, Wyken Pippin; 4, Cobham; 5, Braddick's Nonpareil; 6, Not known (E. P. S.).—Tower of Glamis.

NAMES OF PLANTS (Lady Ring).—Specimen insufficient. (J. P.).—1, *Veronica salicifolia*; 2, *Arctium Lappa*; 3, *Chenopodium Bonus-Henricus*. The insect is a thrips. (M. Fisher).—1, *Sedum Sieboldii*. The specimens of Ferns are very incomplete. 2 May be *Athyrium Filix-femina*; and 3, *Polypodium cambricum*.

POULTRY, BEE, AND PIGEON CHRONICLE.

PORTSMOUTH ORNITHOLOGICAL SOCIETY.

It will be remembered by many of our readers that the Managers of the last Portsmouth Poultry Show did not pay some of the winners their prize money, and this in the face of unusual attractions concerning their payment which the schedule offered. To obtain their dues several exhibitors placed the Committee in the County Court and obtained their money with costs. There are, however, others who did not like to take such steps, and to them a great part of their money has never been paid. Such will be glad to hear that there is yet

a chance of their receiving their prizes, for we learn that a short time ago a meeting was held at the Sussex Hotel to take into consideration the financial position of the Portsmouth Ornithological Society, and to discuss such measures "for the credit of the town" as might be deemed necessary for the discharge of the liabilities incurred and outstanding in respect of the last Show. The Mayor (W. Pink, Esq.) presided at the meeting, and among the number present were Messrs. Good, Cunningham, Cudlipp, Charpentier, Groom, Boots, Wise, Nicholson, Sparks, Simmonds, Westcott, &c. We learn that the Secretary of the Society affirmed that the liabilities amounted to £184 15s. 10½d., and the Treasurer said that the assets only came to £5 17s. 2d. The Mayor remarked that the Working Committee, when they saw the position of the Society, should not have paid some claims in full and some not at all. The Secretary and Messrs. Wise and Westcott also gave their ideas as to the non-success of their Exhibition. The Mayor then addressed the meeting at some length, and said that he "had taken the liberty of asking their attendance that evening to consider the best means to defend and preserve the credit of the borough in this present crisis of the Ornithological Society. There had been small losses on the first and second years, and the Society naturally thought they might make one more effort to clear off the debt and have a small balance to go on with. From what he had seen of the Working Committee everything appeared very hopeful, and he would give the members all credit for doing everything in their power to make the affair a success. In fact, no one could blame them for making the effort to regain their position after the losses of the previous years. Unfortunately the result was a very heavy loss indeed, making a total for the three years of £184 15s. 10½d. Although personally he would be very sorry to admit any liability, nor did the Managing Committee wish it, he did not like to see the Committee being constantly subjected to actions in the County Court. He, therefore, thought the best plan would be to call a meeting and see whether they could not devise some means to meet the creditors, and ask them, under the painful circumstances, to be as lenient as possible in their accounts, or in some way assist the Society to liquidate the debt. If the Committee were to be left open to County Court actions the £184 would soon amount to £260, besides lowering the dignity of the borough and preventing public spirit being shown on future occasions. For his own part he scarcely knew what scheme to suggest, except paying the hard cash out of their own pockets, and if that were done he would gladly bear his share."

Mr. Cunningham then moved that the Mayor should apply to Sir Frederick Fitzwygram for the purpose of obtaining Leigh Park, in which to hold a fête in aid of the Society. This proposition was seconded by Mr. Wise and agreed to by all. A subscription list was then opened, when the Mayor promised £5; Mr. Cudlipp, £2 2s.; Mr. Good, £2 2s.; Mr. Collinson, £2 2s.; Mr. Charpentier, £2 2s.; Mr. Cunningham, £1 1s.; Mr. Cante, £1 1s.; and Mr. Reading, 10s. 6d., which would at once increase the assets from £5 17s. 2d. to £21 17s. 8d., or nearly one-eighth of the total of their liabilities. Afterwards a Committee was formed for the purpose of collecting subscriptions, and the Mayor announced that he would receive donations on behalf of the Society.

We are delighted to hear the Committee have had this meeting, and hope they may have a successful fête, and so be enabled to get some money in hand wherewith the Ornithological Society may once more be brought into life, for we cannot but think that with judicious management such a Society should flourish in Portsmouth.—W.

BLACK HAMBURGS.

Of all the well-known breeds of fowls, this, perhaps one of the most useful, beautiful, and profitable, is less known, and has been, with few exceptions, less described than any other. It has been in this country so difficult to obtain in its full purity, that many of its most ardent fanciers have despaired of ever getting satisfactory birds, and abandoned the pursuit. So-called Black Hamburgs, believed, too, to be such by their owners, can be bought; but the connoisseur can see that they are from a made strain, fashioned generally by crossing the Black Spanish and the Golden-spangled Hamburgs, or else by keeping and interbreeding the darkest Golden or Silver-spangled Hamburgs, and from pure black birds thus bred again interbreeding until the black is perfected. The Spanish cross can be detected by the birds throwing single combs in about a third of the hatch of the season, and also by the combs becoming inordinately large, the ear-lobes long instead of round, and the cocks being rather squirrel-tailed; the birds are, however, finely formed, and the lustre of the feathers equal to that of the Spanish, but rather bluish in tint. The birds bred from dark Hamburgs are very coarse about the combs and heads, thus showing degeneracy, and upon examination in the bright sunlight an iridescent spangle can be discerned in the wing-shafts. No less an authority than Mr. Tegetmeier has cited this last peculiarity as a

characteristic of the pure breed, but it should never be present in a well-bred bird, and when it appears the bird will almost certainly be found to have originated in the Golden or Silver-spangled Hamburg. The true Black Hamburg is a bird whose pedigree, in its purity, long antedated the poultry fancy, and originated in the home of all the Hamburg varieties—Lancashire and Yorkshire. It is the largest of the Hamburgs, and although perhaps not so great a layer as the pencilled bird, lays eggs so much larger that the difference in quantity is made up. The pure bird should be black throughout the feathers, and when in condition the lustre on all the feathers is indescribable, the metallic hue having almost a peacock brilliancy in the sunlight. This hue should never be anything but greenish, although old cock birds sometimes get a coppery tinge, and a bluish tinge is suggestive of a cross. The comb should be of moderate size, with a very long spike turning upward, the wattles and ear-lobes of cock and hen being round, not elongated, and the ear-lobes intensely white and very smooth. The surest indications of purity of blood are the greenish lustre of the plumage, smallness and neatness of the comb, compactness of feather, redness of face, and more than all, narrowness of the back of the head. The last is an almost unfailing indication. The combs are very difficult to obtain of proper shape, the points being often twisted or absent, and the comb itself being very apt to sag over on one side; yet, with all this difficulty in rearing to a proper standard, the bird, from its great beauty, prolificacy, and general useful qualities, has never liked admirers, and the proof of this is the great price a cup bird will bring in England. A very fine cock is so scarce that it is not uncommon for one to be sold for a sum equal to \$100, and the Crystal Palace cup cock of 1875 brought \$400. The most celebrated strain in England is that of the Rev. W. Serjeantson, and such has been the danger of contamination that it is said the strain has never been crossed, the owner preferring to breed together birds of his own strain distantly related rather than injure the strain by any base alloy. Mr. Beldon, the celebrated Hamburg breeder, has sent to this country some very fine birds of his own strain, but as he has not obtained the cup for the best birds of this variety at any of the later great English shows, some of the other well-known strains in England are probably superior. It is greatly to be regretted that the very large prices asked for genuine Black Hamburgs has prevented the importation of very high-class birds, but the difficulty of rearing the variety in its perfection will probably keep up the price and the demand. The variety is of very great merit, and as it possesses, in addition to the beauty of the other Hamburgs, the extra qualifications of size and hardness, is justly regarded as a great addition to the poultry yard, and should be better known. Except perhaps the Silky and Sultan varieties, it is the rarest bird in its purity in this country, and it is to be hoped that the same enterprise which brought from the English breeders to this country so many of our valued strains of other varieties of poultry will be devoted to the importation of this, which is certainly fully the equal of any known, either as a useful or beautiful variety for farmer or fancier.—(*American Pet Stock Bulletin*.)

GIVING OIL TO A BIRD.

IN last week's *Journal of Horticulture* "M. H." is recommended to give his Canary a drop of cod-liver oil by opening its beak and dropping the oil into its throat from a large needle or bodkin. I tried to administer castor oil to a Virginian Nightingale and another bird in this way, but in each case the bird died within a few seconds. No doubt they were unable to swallow with the beak open, but the suddenness of death was remarkable. Another plan of administering castor oil I have seen somewhere and found to be safe and effectual. It was this:—Keep the bird without water for a time (two hours?), then put a drop into the water fountain. The bird in drinking takes the floating oil first, and apparently without much noticing anything unusual.—H. T., *Humshaugh*.

SOUTHWELL SHOW OF POULTRY, &c.

THIS Show is making excellent progress, the number of entries increasing year by year, this time coming almost up to four hundred. *Game* headed the list, and there were some good birds, a great improvement in fact upon those of last year. The winners in the Black and Brown Reds, and the Piles first in the variety class, were very good in all respects. *Cochins*.—Buff very good old birds; the hens slightly pencilled on the necks, but of a good shape and well feathered. In the next class *Partridge* were first and third, and Whites second. *Brahmas* a mixed lot and very good. The winners *Dark* in the first, second, and third. The first a grand pair in colour and marking. *Dorkings* were large but somewhat uneven, some bad on feet and others scarcely moulted. *Creve-Coeurs* were a class such as is rarely seen in size, correctness of comb, and crest. A pen of *Minorcas* were very highly commended in this class, though not strictly a French variety. *Houdans* had two classes. *Cocks*

were a capital lot, old birds carrying off the prizes, and being a strong class those correct in comb were selected as the winners. Hens a fine lot and well shown. *Hamburgs* were unfortunately Gold and Silvers in each class, a system we cannot sufficiently condemn. *Game Bantams* were very good classes. The winning Black Reds were a superior pair; the second stylish, but the cock somewhat out of colour; the third rather large, but otherwise very good. In Brown Reds were some very good ones, especially the pullets. Any other *Game*, first and second *Duckwing*, the first a most stylish bird; second cockerel excellent in style and colour, but pullet not equal; third smart *Piles*, not one clean. Variety *Bantams* very poor. *Ducks* were very good in Rouens and Variety, but *Aylesbury* were poor. The Selling classes were large and good.

Pigeons.—Carriers poor with the exception of those noticed; but the winners were very good—first *Dun* and second *Black*. In *Pouters* first was a capital *Blue*, second and third *White*. In *Dragoons* the Mansfield loft carried off the prizes, and these were very good—*Blue*, *Yellow*, and *Blue-chekquered*. *Tumblers*.—First a good *Almond* cock, second *Blue Bald*, and third a grand-headed whole-feather. *Jacobins* about the best class of the Show. The winners were *Reds*. Some exceeding neat *Fantails* were shown; *Magpie*, *Nun*, and *Swallow* were very good and the competition keen. *English Owls* a fair class, and *Antwerps* a moderate lot. The Variety class was a good one. An *African Owl* was placed first, second a grand *Fairy Swallow*, third a *Satinette*, fourth a *Blondinette*, and fifth also.

JUDGE.—Mr. E. Hutton, Pudsey.

STEWARTON-HIVE SYSTEM.

THE results of my experience with the Stewarton hive in the splendid season of 1876 were duly chronicled in the *Journal of Horticulture* last autumn. I then obtained from a single colony 144 lbs. of super and 6 lbs. of slung honey, a harvest not exceeded, as far as I was able to ascertain, on any exhibition in the kingdom. The past summer has been an unfavourable one here as elsewhere. The crop of white clover was abundant, but owing, I presume, to the presence of a dry easterly wind during the greater part of the time whilst it was in blossom, it never seemed to yield any supply of honey, so that though the fields were white with clover, the bees appeared to be comparatively inactive, and this was characteristic of the summer during the entire season. A little more briskness was observable when the lime trees were in blossom.

The colony above alluded to has, however, yielded a harvest of 63 lbs. of fine super honey. As I only keep bees for amusement, and never sell either wax or honey, I am content with a small number of stocks, and never now retain more than four or five hives for the winter. Having thus only a very limited number of hives from which to make a selection, I think that the success which has been attained is sufficient to demonstrate the excellence of the Stewarton system. The supers have been uniformly free from all trace of brood or pollen, and the use of perforated zinc sheet to exclude the queen from the supers appears to be quite unnecessary. I do not wish to lead beekeepers to suppose that these results are solely attributable to the Stewarton hive, as although I do not believe that a better system of management has hitherto been devised, I am quite aware that a hive of this description would be comparatively valueless in the hands of an ordinary cottager, or of any beekeeper who was unwilling to take the trouble of carefully looking

after the bees, anticipating their requirements, and judiciously carrying out the instructions so fully given by "A RENFREWSHIRE BEE-KEEPER."—J. E. BRISCOE, *Albrighton, Wolverhampton*.

COMB FOUNDATIONS.

It is pleasing to find at page 335 "the captain on the paddle-box." Mr. A. Pettigrew, like a second Rip Van Winkle, arousing himself after a fifteen-years slumber, with a piece of comb foundation in his hand, beginning to take stock of the march of apian progress during that period; and on the same page Mr. P. H. Phillips confirmed the opinion I expressed last spring as to the Ligurian bee "being first to scent the new flower and first to alight on the treasure trove." I remember perfectly the beautiful orange colouring of the Italians which they on the first day of their arrival displayed busily at work on the scarlet monarda, a flower I never saw visited by our old black aborigines.

As to the wax sheet, for the sake of historical accuracy it becomes necessary to explain to Mr. Pettigrew as well as the recent subscriber that the above invaluable production was not, as he supposes, of American but German invention. I first saw it in 1862, when the late Mr. Woodbury enclosed a small portion in a letter for my inspection; and to the enterprise of Messrs. Neighbour & Sons, London, entire imported sheets found their way into Scotland the same year, and the idea at once spread like wildfire. Were a mould once devised the advanced bee-keeper for a consideration could not alone save the condemned bees of the skepists, but utilise their bruised-up irregular combs, passing such through the machine to re-appear as straight regular guide-comb foundations for frame hives and bar supers. Numberless were the schemes and endless the materials called into requisition to effect the purpose, such as paper, wood, stucco, gutta percha, lead and other metals; but "honour to whom honour." To that most ingenious apian "A LANARKSHIRE BEE-KEEPER" is due the credit of being the first in the United Kingdom to invent a pair of plates which could cast embossed wax sheets to vie with the imported, and to his energy in their manufacture is to be ascribed the rapidity with which they became an indispensable requisite in every well-managed Scottish apiary. It was not till the Crystal Palace Show of 1874 that our southern brethren discovered how far we northerners had outdistanced them for straight work, and that the wax sheet and its manufacture became diligently inquired after.—A RENFREWSHIRE BEE-KEEPER.

BEE-KEEPING EXPERIENCE.

I HAVE completed my first year's experiment in bee-keeping on Mr. Pettigrew's system with tolerable success. Last year I formed seven stocks from swarms obtained from my villagers in September, all of which came safely through the winter, and this season reached weights from 44 to 64 lbs., the heaviest being in an 18-inch hive, the others in 16-inch hives.

This autumn I have formed three new stocks of two swarms each. It is about these I ask your advice. They took syrup well enough at starting, but gave up before they reached a good weight. On weighing them yesterday I found that two of them are 12 lbs. each and one 14 lbs. They do not consume more than half a pound of sugar each in a fortnight, but the bees are full of strength and spirit, and rather saucy, as the people here say. What should be done to these new stocks, and what am I to expect from them? Will you kindly favour me with any instruction?

I find by my notes that the consumption of stored honey last winter varied considerably. From the middle of September last year to the middle of March this year No. 1 hive consumed 14 lbs.; No. 2, 20 lbs.; No. 4, 6 lbs.; No. 5, 8 lbs.; No. 6, 9 lbs.; No. 7, 11 lbs.; No. 8, 9 lbs. My first year's success has made an impression on my rustic parishioners, and for their sakes as well as my own I should not like the favourable prestige to be impaired.—H. G. W. AUBREY.

[As this gentleman has made a good beginning in a very unfavourable season he need not fear that the favourable impression made on his bee-keeping parishioners will be diminished by non-success in future. He is much more likely to deepen the impression already made, and teach them a valuable lesson by a success in bee-keeping which he does not at present seem to anticipate. From the apiary he has established he may expect a large harvest of honey next season if it be a favourable one.]

His three new stocks will require a little more feeding, as they are rather light at the beginning of winter. In mild weather, even at this late season, bees will take up good warm syrup readily. In cold weather hives without food can be fed in a warm room or hothouse at night and carried into the garden before sunrise. Probably these three new stocks have not made much comb, and the bees are at some distance from their boards. If warm syrup be poured into a flower-pot saucer or dish of any sort, and placed so as to touch the combs, the bees in moderately mild weather will readily take the syrup. We have

no difficulty in getting our hives to take syrup in quantity. Many of them would take 3 lbs. of syrup in three hours if presented to them now in the manner indicated above. The figures which Mr. Aubrey has favoured us with, touching the consumption of food in winter, will help him and others to determine how much swarms should have in autumn.—A. PETTIGREW.]

OUR LETTER BOX.

POLANDS CROOKED-BREADED (W. A. W.).—A crooked breast is always a grave fault, if not a disqualification, in a cock. Polanders are not always handled, and if they are not the defect would not be discovered. The crooked toe nail is not so important, and there is no objection to your trimming it. It is not at all material, as it is likely to be an accident. At small local shows the birds are often shown in the baskets in which they are sent, but at most shows they hire proper pens. You will do well to ascertain the fact, as a basket that would do well for travelling would make a very bad exhibition pen.

SILVER-SPANGLED HAMBURGS (J. B.).—We advise you to avoid the extremes, and to choose your stock neither dark nor light. See that the spangles or moons are sharp-cut and well defined at the end of each feather; that the breast be accurately spangled, and that the tail feathers be quite white with the exception of the spot or moon at the end of each. Be very mindful of the hackles. A clear hackle is as great a fault in a Spangled Hamburg as a clouded one is in a Pencilled. But it must not be black, it must be made up of the two colours blended together. The better the lacing and barring of the wings the better the bird. Be careful that the comb is well piked and turning upwards, and above all that it be not loose or incline to either side. If you must choose between light and dark, choose dark. They will get lighter, but the light will not get darker.

PIGEONS AT TOOTING (An Old Fancier).—"WILTSHIRE RECTOR'S" visit to Mr. Vander Meersch, in which he describes his Pigeons at Tooting, is in our number for April 1st, 1875. You can have copies at 4d. each.

DORMICE (K. A. T.).—We know of no work on their management. They only need to have their kept clean, and a few nuts and a pan of water in it in case they rouse up.

BOOKS (X. Y. Z.).—"Domestic Pigs," by H. D. Richardson.

REMARKS.

31st.—Fine, very bright clear morning, dull afternoon; fine starlight night.
1st.—Very bright fine day; misty in after part of afternoon, and foggy at night.
2nd.—Very foggy morning; fine day, short shower in evening.
3rd.—Fine bright day, foggy at night; stars shining at 11 P.M.
4th.—Thick white frost in early morning; fine pleasant day throughout.
5th.—Very fine warm day, hot sun; misty towards evening and rain in the night.
6th.—Wet and dull throughout; windy in evening.
A mild and rather damp week, with hot sun on two or three days.—G. J. SYMONS.

COVENT GARDEN MARKET.—NOVEMBER 7.

OUR market is very quiet now, the supply of good Apples having materially fallen off this last week. Pears are still reaching us in good quantities from France, and consist of Duchesse d'Angoulême, Glou Morceau, and Beurré Diel. Pines meet with a ready sale. Kent Cobs are quiet.

From observations taken near London during forty-three years, the average day temperature of the week is 43.7°; and its night temperature 34.1°.

WINTER PRUNING OF FRUIT TREES.

Y many writers the pruning of fruit trees is made to appear as one of the most scientific matters connected with gardening. To such an extent is this carried in numerous instances that many amateurs and owners of small gardens who do their own gardening are frequently deterred from pruning their fruit trees altogether. They are so much afraid of "doing them wrong" that they prefer not doing them at all, which results

in much injury to the tree, and deficiency in both quantity and quality of the fruit. Pruning is a simple operation, easily imitated from practice or learned from reading. The following notes are written without any pretensions to science or mystery, and those who put them into practice may rely on keeping their fruit trees and bushes in shape and in good bearing order. The winter pruning of all fruit trees may be done from the middle of November until the end of March. It is of no use saying, Only prune when the weather is dry and free from frost. It is very seldom we are so favoured in the winter season, and, excepting in extreme frost or snow, we practise pruning.

APPLES.—I may assume without being far wrong that all fruit trees are well pruned and trained so long as they are in a young state in the nurseryman's hands. On receiving fruit trees from the nursery it will be seen that the branches are not crowded or growing across each other, and one is a good distance from another. No better example could be shown or taken than this for all future guidance in pruning. In pruning both young and old Apple trees always cut out all cross-growing shoots: where this will cause a large vacancy leave a bud or two at the bottom from which a straight shoot may spring up. Where it is desired to have the trees low, cut the straight young shoots well down that they may send shoots out underneath. In young trees it is always best to lay a good foundation by cutting them close-in for a year or two at the first, because when they are allowed to become straggling at first it is very difficult to get them into form again. Where many shoots are growing together cut all the weakest clean out, and shorten about halfway back those that are left. When it is desired to make a tree into any particular shape pruning must be done accordingly. In old trees cut out all long budless branches, and let the nearest young shoots take their place. Never cut away a branch with a lot of blunt-pointed fruit buds on it. Cankered half-dead wood should never be allowed to remain. Where the branches are not wished to be extended any further cut all the shoots made at their points this season close in to the old wood. Always let the shoots extend outwards; never allow them to become jammed in the centre and thin and straggling at the outside. Young trees will want the centre shoots thinned and shortened, old trees must have the dead branches cut out and all this year's wood not needed cut-in to one eye, or two, from last year's wood.

PEARS.—These are pruned somewhat after the style for

the Apples. They always bear on the spurs, and as many of these must be secured as possible. Standard or bush trees must have all the young shoots cut-back where they are not wanted, but they should not be cut quite so close as the Apples. It is very seldom that any of the round-pointed fruit buds require to be thinned, but where they are crowded cut out the weakest. With trees on walls, if the branches are being extended, only take a small point from the leading shoot which has been formed in summer, and all the young shoots which are growing straight out from the wall on last and former year's wood must be cut-back to the third or fourth eye.

PLUMS.—Most Plums resemble Pears very much in their habit of growth and mode of fruiting. We prune our wall Plums just the same as the Pears. Bushes have their shoots well shortened, as the branches are so liable to grow small and bear down on one another. Any old trees which have not been pruned for years should have all the small trash of branches cut clean out of the centre, and all shoots some yards long with only a few buds at the point must be cut away also.

APRICOTS.—These are just pruned like the preceding, but sometimes they do not grow so luxuriant while young, and therefore are not cut so much until they have become established; but at the same time they are never allowed to grow out of shape. Old trees produce many fruitless shoots amongst the fruit buds on the spurs, these should all be cut-in to the first or second eye.

PEACHES AND NECTARINES.—These require about as much care in pruning as any kind of fruit tree. They do not like being cut too much, but at the same time they will not do without being pruned. It may be thought that the directions for pruning such important fruit trees must make a long article, but such is not the case, as the whole operation may be stated in very few words. Peach tree shoots which start from the main stem soon grow a considerable distance, and they have a great tendency to become budless as they proceed. The results of this may often be seen in trees with nearly leafless and fruitless centres. When pruning is annually done this may always be avoided. In spring time when disbudding the tree leave one young shoot to form a branch at the very base of the previous year's wood. In pruning now cut all the wood in front of this shoot away and let this shoot be nailed or tied-in to fruit next year. By doing this no tree will become bare of young wood on one part and crowded on another. The Peach and Nectarine always fruit on the young wood, therefore save as much of this as possible. Unless the shoots are extremely long do not cut much from their points, but a little should always be taken off each shoot, because very often the extreme bud is a fruit one, and it is always desirable to have leaves at the point, which may be secured by cutting in front of where a small bud is seen in the centre with a large one on each side.

CHERRIES.—All young shoots on bush trees not wanted to extend the tree should be cut-in to 2 inches from the old wood. Wall trees must have the best of the shoots nailed-in, and cut away all small unripe twigs.

GOOSEBERRIES.—Some of the above fruits are not grown in every garden, but now we come to a class of fruits grown everywhere. In pruning Gooseberry bushes keep the centre well open; do not let the branches cross one another; cut all shoots formed this season into half an inch from where they join the old wood. When the bushes are large enough cut the leading shoot in the same way. In extending them do not leave more than 6 inches of young wood on in one season. A well-formed and pruned Gooseberry bush should have each branch surrounded with clusters of short spurs with no long projecting pieces sticking out from various parts.

CURRENTS.—In the case of young Red and White Currant bushes have the shoots thinned where too close, and shortened to not more than a foot. Where no young branches are wanted on old-established bushes every young shoot must be cut off, leaving only about half an inch attached as a fruit spur to the old wood. Black Currant wood is never shortened. The oldest wood is cut away every winter to give place to the new. As soon as both Currants and Gooseberries are pruned the prunings are cleared off the ground, a good quantity of dung placed round and between the bushes and forked-in about 3 inches from the surface. This is a good plan to keep the bushes fruitful and vigorous.

RASPBERRIES.—All the old canes of these are cut off at the surface of the ground and thrown away. The strongest canes made during the season are put in their places, and all the smaller not required are either cast away or lifted with roots to make fresh plantations. Good manure is spread on the surface of the roots, but not forked-in; the centre of the rows only, where there is not many roots to disturb, is turned over.—A KITCHEN GARDENER.

SPECULATIONS AS TO THE NATURE AND ORIGIN OF THE POTATO DISEASE.—No. 1.

The Potato is believed to have been introduced into the United Kingdom from Virginia by Sir Walter Raleigh in the beginning of the seventeenth century, and was cultivated on his estate in Ireland and in other parts of that country in a small way for many years, and about 1694 was introduced into Lancashire, where its cultivation soon became general and gradually spread over the other counties of England; and if we allow several more years from 1694 for this to have taken place, say until 1745, the Potato must have been in general cultivation at least a hundred years previously to 1845. For many generations the Potato was cultivated year after year, as before mentioned, and as far as we know no sign of disease exhibited; indeed I consider it impossible a disease so virulent in its nature and so rapid in its extension could possibly have existed without being known, when all on a sudden it appeared and spread rapidly over a wide range of country. That is difficult to understand. How did it arise, and where did it come from? An able botanist not long ago came out with the astounding statement that everybody was convinced that the fungus was the disease. This was going a little too far: the general public were by no means convinced, and are not now. I am willing to confess, however, that I am inclined to agree with the botanist.

Some persons think that the plant must first be in an unhealthy state, and that it must be in that condition before it is liable to the attack of the fungus. That is so, undoubtedly so, with regard to many other plants, as almost everyone must have observed who has had much to do with plant cultivation; but if we take that view with regard to the Potato we are not much nearer the mark than before. What were the particular conditions that prevailed at that time and have continued more or less ever since? That is as difficult a question to answer as to find out the origin of some of the diseases which affect the human subject. Did Adam suffer from the measles, &c., and if not, why not? would be a very good question for the medical student.

It would simplify matters very much if we could only believe in spontaneous generation, but we should want some stronger evidence than we seem likely to get for a long time yet. Professor Tyndall must try a great many more experiments with his boiled infusions of hay before he will be able to bring forward any very satisfactory evidence on that question. I may as well at once admit that I do not believe in spontaneous generation, and therefore abandon it.

The cause of the disease is again supposed by some writers to have been from the degeneracy of the tuber, or some peculiar state of the atmosphere. If the disease arose from the first

cause, those raised from seed and those which are carefully cultivated ought to be free from the disease, but they are not; and if it arose from some peculiar atmospheric influence, what a remarkable thing it was that a change should have taken place about 1845 and should have continued down to the present day, and not only that this change took place here but over the whole inhabitable globe.

The British Consul in Poland wrote to Lord Palmerston on the 16th of October, 1846, stating that the only known case of Potato disease in that country occurred in some plants of the Ashleaved Kidney, the tubers of which had been obtained from Britain and treated in exactly the same way as the common Polish crops; and it adds, "This circumstance would seem to prove that the disease is not attributable to atmospheric influence, as I hear is the generally received opinion of other countries. Here in Poland all persons to whom I have spoken on the subject think that the Potatoes in the rest of Europe are tainted in the germ by over-cultivation; and it is certainly remarkable that here where the soil is generally light, and where less manure is used than in any other country except Russia, and never immediately preceding the crops of Potatoes, those plants should have completely escaped the infection which threatens their extinction in all parts where greater pains have been taken with their culture." I think the writer, although he wrote thirty years ago, was right in his conclusions that the disease was not attributable to atmospheric influence, and he might have gone a little further and said it was plain the disease was taken there with the English Potatoes. And then with regard to the degeneracy of the tuber from over-cultivation and the use of a large quantity of stimulating manures—bad things, no doubt—the disease ought to have originated in the north of England and Scotland, where these malpractices were carried on; but no, it began in other places before it reached there; therefore we must seek some other cause.—AMATEUR, Cirencester.

WHAT ROSES SHALL I BUY?

Now that the result of the exhibition-Rose election is in our hands, and aspirants for distinction at the shows are seeking its guidance to add to the ranks that are to do battle for them, I think a little advice from some experienced and skilful general as to the proportionate numbers of each Rose that it is best to enlist would be useful.

Imagine one who was a bad fourth for six varieties at a show during the past summer, eager for higher honours, ordering a dozen each of the twelve Roses standing first on the list. It needs but a glance at the names to see that he would be disappointed when he sallied forth to cut his blooms for the show to which he had so eagerly looked forward. He would be embarrassed to decide upon the best of three or four blooms of one variety, while for a passable specimen of another he would search in vain.

I will take the first twenty-four, not as pretending to guide, but to explain what I mean. Would not the quantity of each kind required to ensure an even box of twelve be something like the following, taking the numbers to represent dozens?—

- | | |
|----------------------------|--------------------------|
| 1. Baronne de Rothschild | 5. Ferdinand de Lesseps |
| 2. Marie Baumann | 6. Catherine Mermet |
| 3. Madame Victor Verdier | 6. Mlle. Eugénie Verdier |
| 3. La France | 6. Comtesse d'Oxford |
| 3. François Michelon | 6. Marie Raby |
| 3. Etienne Levet | 7. Sénateur Vaisse |
| 4. Charles Lefebvre | 8. Duke of Edinburgh |
| 4. Alfred Colomb | 12. Louis Van Houtte |
| 4. Marguerite de St. Amand | 18. Xavier Olibo |
| 4. Dr. Andry | 18. Emilie Hausburg |
| 4. Marquise de Castellane | 25. Horace Vernet |

The last three Roses should hardly find place in so limited a collection perhaps. Maréchal Niel and Edward Morren I have not mentioned, as the former is estimated rather by the square yard (or square mile if one can), than by the number of plants, and the latter is so uncertain, being dependant on the season, that it is difficult to say what number of plants one should have. It should go perhaps in the same category with the last three on my list—viz., Roses which it is much desired but little expected to be able to show. Will some one be so good as to correct me and extend the list?—HUBERT BENSTED, Maidstone.

DIONÆA MUSCIPULA (VENUS'S FLY-TRAP).

E. PAYNE, late gardener to Mr. Foreshaw, writes to the Editors that I have done him an injustice in reference to the notes I sent on this plant. He says that it is "untrue that

Mr. Black has potted most of Mr. Foreshaw's exhibition plants for the last three years." He says the plant in question was purchased by him from Messrs. Veitch in October, 1871 (two small plants in 60-sized pots), and was grown-on from that date in the same house and place in which I saw it. He further says that he has known Mr. Black for "many years and the situations he has held as gardener, but never knew him to have a single plant of *Dionæa* under his care, and that the treatment Mr. Black gave to me is entirely without practical experience."

My answer is that in the summer of 1876 I visited my friend Mr. L. Black of Fulwood, near Preston, and amongst other small places he took me, through the kindness of Mr. Payne, to look at Mr. Foreshaw's plants. The pan of Venus's Fly-trap struck me at once as an example of skilful management. Thinking it would interest the readers of the Journal I wrote to Mr. Black asking him to obtain me some notes on its culture from the gardener, with whom I had no personal acquaintance. Mr. Black wrote me to say that the gardener who exhibited it at Preston this summer was not the same whom I saw last year, but he stated that the plants were considerably stronger than when I saw them. He also gave me the information that has been already published in this Journal. Mr. Black's own words are these, alluding to the *Dionæa muscipula*, "I have had to do with the plant; in fact, I have potted nearly all Mr. Foreshaw's exhibition plants (the owner of the Fly-trap) for the last three years, consequently I can give you all the *pros* and *cons*." I have known Mr. Black for nearly twenty years, and do not think he would have made this statement unless it was true, especially as he knew I wanted the information in order to publish it for the benefit of others; if he has done so the responsibility is his, not mine.—J. DOUGLAS, *Loxford Hall Gardens*.

GRAPES CRACKING.

In "J. S. W.'s" otherwise interesting paper on this subject I think he is a little inconsistent when he blames me and my theory for not preventing his Grapes cracking, and yet takes particular pains to tell us he has made no attempt to carry the said theory into practice. I do not suppose for a moment that I could manage "J. S. W.'s" Grapes better than he can himself, taking all points into account; but I do think I could stop the cracking, although the cure in the first attempt might be nearly as bad as the disease, as I have distinctly shown it was with me in one case of overdoing it.

I think the last paragraph but one in "J. S. W.'s" paper rather strengthens my recommendation to take off a few leaves to diminish the flow of sap. It runs thus—"It is a curious fact that in the case of the Vine at the end of the house the sun shines directly on the bunches for a long while every afternoon, whereas on the other Vine where there is so little cracking the bunches are much shaded, as the Vines are trained only 2 feet asunder."

Has it never struck "J. S. W." that half a dozen leaves on the Vine at the end of the house where they get so much direct sunlight, will probably elaborate more nutriment than double the number of leaves would do in the middle of the house where they are crowded and partly shaded by other leaves? Mere area of foliage, however luxuriant, is not worth reckoning unless it is exposed to the light. I do not place any value at all on the sunlight reaching the berries of black Grapes, but I do place great value on it reaching the foliage, as among other things it makes the pumping apparatus work much faster; it puts on more steam power, as it were—sometimes, indeed, too much, as in the case of "J. S. W.'s" Vine at the end of the house.

As this subject is an interesting one and is not yet by any means exhausted, I will jot down a few other thoughts concerning it which occur to me at the moment.

Saturation of soil does not cause cracking unless it has been preceded by comparative dryness, and even then cracking would not occur were there little or no foliage on the Vines. When the border has been allowed to approach dryness so that the berries have ceased swelling and the skin has commenced hardening, and water has afterwards been applied while the foliage was still vigorous and able to take it up, the berry would be very likely to start swelling afresh, and if the skin had become so much hardened as to have lost its elasticity of course it would crack. I consider it a very great mistake to cease watering when colouring commences. I like to see black Grapes, perfectly green leaves, and hard brown wood all

at the same time, and then it looks well for another year. These are often not attainable if there is any stint of water.

Saturation of atmosphere will cause cracking, especially if it is accompanied with a sudden rise of temperature so as to produce condensation on the fruit. We know that the berries can be made to swell tremendously in such an atmosphere, but if it does not cause them to crack they swell at the expense of colour and quality.

In my experience cracking and shanking are not contemporary to any extent. An odd berry of course may be found to support the opposite theory, and the one evil may follow the other speedily from altered circumstances, though the alteration may not be visible to many people. Too little foliage as compared with the weight of fruit will cause shanking or imperfect colouring, and a superabundance of foliage on such Vines as are predisposed to have cracked berries will very likely make them crack.—W. TAYLOR.

It is said, I know not on what good grounds, that Grapes out of doors do not crack. I never grew them, but I think it improbable. Plums and Pears certainly do crack, and I think that most people must have noticed that this occurs when a dry atmosphere is succeeded by a very moist one. I think the analogy holds good with Grapes under glass. This year we had, when some Trentham Black Grapes were half coloured, bright and dry weather. Of course atmospheric moisture had been discontinued in the house as far as it was under our control. This was followed by several days' rain and cloud, with excessive atmospheric moisture. One morning on looking up I saw dozens of berries cracked, with the juice quite fresh; they had all cracked in the night. It occurred to me that if I could keep the air drier it would probably prove a remedy. I immediately had the fires lit, although in the end of July, and put the top ventilators open night and day. The next morning there were only two or three more berries cracked, and after that it ceased. Some three weeks afterwards we had another spell of dry weather, and then again rain and damp. Some other Grapes on other Vines cracked, and were again stopped in the same manner.

I am much inclined to think, therefore, that a sudden change from a dry to a moist atmosphere is the true cause of Grapes cracking, and that they could be brought under control by fire heat with top ventilation. I hope some of our more experienced growers may be induced to experiment in this direction and state the benefit of their experience.—J. R. B.

THE CARNATION AND PICOTEE.

Two or three months ago a list was given of the best varieties of these plants, and also some descriptions of the best houses in which to flower them. The season we have just passed through may be said to be very exceptional. Letters are before us from growers in districts wide apart from each other, and all agree in saying that the season has been the worst they have ever known. This applies principally to the midland and northern districts. The growers were not able to layer the grass until the very last week in August and later, and even at that time it was not in good condition. The result of this is that much of the stock is not yet rooted, and some good varieties that we expected to be sent out this season will have to stand over until next year. As I expected, the choice collection of Mr. Ben Simonite at Sheffield has suffered very much, and he is also late with his plants. The growers about Manchester are quite as late, and as we go further north the difficulties of the situation are more numerous. Down south the elements have been more propitious. I was able to layer the largest portion of our plants by the first week in August, and when the layers were taken off they were all rooted except about twenty or thirty pairs. These have also been taken off and potted, but they are treated differently from those that have roots attached to them.

The best place for layers which have been potted (one in a small 60 or two in a large 60) is a common garden frame. I plunge the pots to the rim in cocoa-nut fibre refuse, and give abundance of ventilation whenever the weather is suitable. The plants require just sufficient water to keep the soil moist, and it ought not to be applied to the foliage. This year, owing to the layers not rooting well, we found it necessary to place a number of those that had no roots in a gentle bottom heat, keeping the glass lights close for a week until the layers had emitted roots; after this time more air is admitted, and during calm nights when the dew is falling the lights are removed,

replacing them again in the morning when the sun touches the frame. Carnations are subject to the attacks of green fly, and if this is not kept in check good results cannot be obtained. We have destroyed the insects in two ways—by fumigating with tobacco smoke, or dusting the foliage with dry snuff or powdered tobacco. When the lights fit tightly two or three nights' smoking will destroy the pests. If this is not the case it is necessary to dust the foliage. Dipping the foliage in soapy water to which has been added a little tobacco liquor, has also proved destructive to the insects.

In order to be successful yellow loam containing a good percentage of clay must be procured for potting the plants; to this must be added leaf soil and decayed manure in the proportion of 1 to 5, and an 8 or 9-inch potful of sand to each barrowload of the compost.

Some varieties are much more delicate than others. They make very slender growth, and the leaves die off near the base; but as many of these have the finest flowers and are almost indispensable to the exhibitor, they must be kept in good health if possible. It requires some experience to be able to give each variety the treatment best adapted to it, but as a rule weakly growers require a lighter compost made porous by a larger proportion of sand. Others, again, grow with too much freedom; these will be better with a smaller proportion of manure, leaf soil, and sand. They may also be turned out of doors earlier in the spring than the others.

Most of the varieties of Carnations and Picotees are grown in pots at Loxford, and if it is intended to plant any out in beds the more robust growers are selected for this purpose. Varieties wanting in colour do best in beds; high-coloured sorts, on the other hand, are not improved by being planted out. A friend in the north of England has kindly promised to send me a few notes on the method pursued there with them. I hear that they grow none in pots, but plant all the varieties in the open ground. They seem to grow the plants two years on the same ground; the second year they term it "growing them on the bush." The method we used to pursue in Scotland was this: About this time of the year the ground was trenched 2 feet deep, working-in at the same time plenty of decayed manure. On the surface of the bed some fine maiden loam was placed, and in this we put out the plants early in March about 18 inches apart. The plants do not require so much attention in beds as they do in pots; but we much prefer pot culture when they are in flower, especially if they are wanted on a given day for exhibition, as the pots can either be shifted to a cool place to retard the flowers, or to a warmer position to bring them earlier into bloom. Mr. Rudd of Bradford, an ardent cultivator and exhibitor of this flower, has noticed a singular circumstance in regard to plants obtained from the north, where they grow only in the open ground: he has found that such plants never do well when grown in pots the first year, it generally requires a season to bring them into good condition. Another circumstance which cannot readily be accounted for is, that certain sorts die off without any apparent cause, although they may be as healthy as the others at the time of potting. I had three pairs of one of the new varieties this year, which died off, and had to obtain another supply.

Those intending to purchase plants should do so at once, as the demand for certain choice varieties may be greater than the supply. I prefer the plants taken direct from the stools and sent carefully packed in moss and wrapped round with paper. When they come home packed like this they ought to be potted without delay and be placed at once in a cold frame, shading from the sun for a few days. It is not necessary to give names of the varieties, as this has been done so recently, but the above notes may be useful to those who are forming collections and whose experience is limited.—J. DOUGLAS.

NEW VARIETIES OF POTATOES.

SOME of the new sorts I grew this season are very promising. Schoolmaster is a very good variety; it bears well and is very little diseased. I planted 1 lb., and the crop weighed 30 lbs. when I lifted them, and had it been a good season for swelling the tubers I believe there would have been 50 lbs. There were exactly 29 feet of a running yard for 30 lbs. Yorkshire Hero is a free grower and bears profusely and good quality: there were a fifth of them blighted. Alpha is a good early sort, but more subject to blight than the Schoolmaster. Covent Garden Perfection is also a good sort, and Porter's Excelsior is a good early—the true sort of it. Climax, Dalmahy, Rintoul's

Striped, White Dons, Myatt's Kidney, and White Regent were very bad with disease. The Blue Regent stood very well, but the Champion is a dreadnought sort and bids defiance to the tainted atmosphere which some think is the cause of blight, and everyone has a right to think. This sort originated in Forfarshire three or four years ago, and is deservedly getting into favour. I grew some of it, and it bears well and is of very good quality and resists the blight, and if it is treated in a proper way it may be the sort grown for years. A farmer near Dundee has fifty acres of it, and he sold thirty of them and received £50 an acre, and half of the cash paid down when bought. There will be a rush for it for next year. A good many of the farmers here have grown a few and are much pleased with them. They bear seed freely.

As a rule the disease is associated with rain, thunder, &c., but I saw it one year in Ireland in a very dry season. I was then gardener to the late Earl of Shannon, Castlemartyr, and in June the Earl sent me to London to see some of the sights there; and when I returned the grass was burned up, and there was no rain for long after that, and the early Potatoes were much blighted, and I really wondered at it, but it is a fact. This and the Champion resisting this awful blighty season will be a hard nut for one of your correspondents to crack, and who believes it is entirely an atmospheric affair. The new and hardy varieties must be grown, and if properly treated there will be less dread of a wet season destroying them.—J. ADDISON, *Ormiston, Edinburgh.*

GLOUCESTERSHIRE ROOT, FRUIT, AND GRAIN SHOW.

ONE of those exhibitions of farm produce which usually take place in the rural districts at this season of the year was held in the Corn Exchange at Gloucester on Friday last under the auspices of the Gloucestershire Root, Fruit, and Grain Society. The Society has been in existence for fifteen years, and they have held a show annually on the 9th of November, their object being to encourage the production of superior samples of roots, grain, fruits, cider and perry, which are the staple productions of the district. We shall confine our observations to the fruit, the other objects being outside of our department.

In an unfavourable season like the present we did not expect to see such a large quantity of fruit as was exhibited. One wide centre table running the whole length of the Corn Exchange was occupied with Apples, and a cross table was furnished with good collections of dessert Pears. The Apples were divided into classes, as Dessert, Culinary, and Cider fruits, and there were also classes for special subjects of each of these. Upon the whole, considering the unfavourable season, the quality of the fruit was good. In the competition for a collection of dessert Apples the first prize was awarded to Messrs. J. C. Wheeler and Son, the eminent seedsmen of Gloucester, and the second to Earl Ducie of Tortworth Park. Both collections contained superior specimens, and they were all correctly named, which is an unusual occurrence at exhibitions of a similar nature.

We never saw such an exhibition of Ashmead's Kernel as was shown on this occasion. It being a Gloucester Apple, raised within the city precincts, it had a special class to itself. The response was good, for there were no less than seventeen entries, all of which were very meritorious with one or two exceptions only. The successful competitors were Mr. Daniel Phelps of Tibberton first, and Mr. Thomas Cadle of Longcroft second. The soil of Gloucestershire seems to be specially adapted for this excellent Apple, for nowhere do we find it produced in better condition than it is here. The class for Ribstons was also good, but there were only nine entries; the first prize falling to Mr. Barnes of Hucclecote Gardens, the second to Mr. Organ of Breadstone, while those of Earl Ducie were highly commended. These three were all very excellent dishes. Of the class for Nonpareils we could not speak very highly, but of the Brandy Apple or Golden Harvey we never saw them surpassed if even equalled. Mr. C. E. Wells of Minsterworth showed a dish which were larger than any we have ever seen and most beautiful in colour: they deservedly received the first prize; while those of Mr. T. Cadle of Longcroft, which were second, though not so large as Mr. Wells's they were equally fine in colour. In the class for twelve dessert Apples of any other variety Mr. Chadborn of Barton House and Mr. Deane of Boyce Court were respectively first and second with Adams' Pearmain and King of the Pippins. The prizes for collections of dessert Pears were taken by Mr. B. Littlewood, The Greenway, first, and Earl Ducie, Tortworth Court, second; both collections being very meritorious. The prizes for twelve dessert Pears any other variety were both taken by Marie Louise; Mr. Phelps of Berlingham, Pershore, being first, and Mr. Littlewood, The Greenway, being second.

The Grapes were not superior; but the culinary Apples were

excellent. In this class Earl Ducie was first, and Messrs. J. C. Wheeler & Son second. It is worth remarking, again, that in these as in the dessert Apples, where these two competitors were also successful, there was not a variety that was wrongly named. There was a special class for Blenheim Orange, and the first-prize fruit of Mr. Mayo of Base Court were of a very brilliant colour, and of fine size and form. For culinary Apples (not Blenheim) Mr. Phelps of Tibberton was first with Alfriston, and Earl Ducie second with Warner's King.

A soil and climate that can produce such fruit as the Ashmead's Kernel, the Golden Harveys, the Ribstone, and the Blenheims that took first prizes in their classes ought, we think, to be used to better purpose than they are, if we may judge from the state of the orchards which one finds, not only in this but in the adjoining counties of Worcester and Hereford. Perhaps we ought to except Worcester, for during the past twenty or twenty-five years great progress has been made, particularly in the Vale of Evesham, by the introduction of the modern system of fruit-growing; but still with that exception all three of these fruit-producing counties do not yield anything like the return they ought to do if a better system of orcharding were practised. With the facilities of railway communication with which they all are served they ought to produce a great supply of far superior fruit to the leading centres of consumption than they do.

We were pleased to see among the collections of cider Apples so many of the famed old varieties still in existence—the Red and Yellow Styres, Hagloe Crab, Redstreak, Cowarne Red, and Skyrme's Kernel. These of themselves if widely planted and properly cultivated would bring wealth in the quality of the cider they produce. How is it, then, that in the collections of cider Apples that were exhibited we found so many that were no better than trash, without names and without character? And how is it that orchardists will grow such trash when they know them to be so? It must be indifference or ignorance of their own interests that is the cause of it. A valuable Apple occupies no more space and requires no more care than a wilding does; and when farmers are so careful to improve the breeds of their cattle, knowing that a high-bred animal eats no more and perhaps not so much as one of a baser breed, it surprises us that orchardists have still to learn that there is as much method, skill, and science in good orcharding as there is in cattle-breeding. The cider which the district round Gloucester produces, when produced as the prize sample exhibited by Mr. Organ, is so superior to the wretched stuff that is sometimes met with under the names of hock and claret, that if it were to be introduced pure upon the market it would displace all of these, and the public would possess a wholesome palatable beverage while the producers would become enriched for their pains. We do hope that this Gloucestershire Society—working in its own district, while the Woolhope Club is working in the same direction in the neighbouring county of Hereford—will be successful in opening the eyes of the orchardists to the pursuit of their own interests, and that the landowners of these counties will also see that by encouraging the development of this industry they are adding vastly to the value of the fee simple of their estates, at the same time that the public are benefited by a large addition of wholesome food and wholesome beverage.

JOTTINGS ABOUT VEGETABLES.

To account for the many diversified opinions—say for instance in the cultivation of Grapes—I have concluded that a generally industrious person may indulge in any particular hobby of his own; if it be the most whimsical or even detrimental his other good properties outweigh this one mischief, and he succeeds. In the growing of vegetables the man who manures well may indulge in whole group of whims. "Muck's the man which makes this mare to go." But this assertion even requires qualifying. When an old garden has been manured and cropped, and cropped and manured, for perhaps a time further back than of which anyone has any remembrance, then this garden has probably become "muck-sick"—its continuous repetition of the same kind. Vegetables refuse to feed longer on one diet *in infinitum*, they require change. New life is needed. Everything burnable, even to the very soil, wants burning. Lime is much needed, and roadside scrapings or soil from wherever obtainable, and soft burnt clay from a brickyard is desirable.

Regarding manuring land in "good heart" and with a good clay bottom you may place the manure where you like, your vegetables will find it. A gravelly bottom is simply an insatiable devourer; it takes unreasonably, and still craves for more. To bury manure deep in a gravelly bottom is simply giving the gravel all the chances of first swallowing the lion's share. By surface manuring or mulching all the while it is gradually penetrating, say through the first 18 inches, every

hungry root is gobbling it up as fast as every root can. The thinking gardener never manures regardlessly; he puts every shovelful where he judges his crop will be most benefited. I will speak of Cabbages first. Having seven thousand to plant last autumn, in good time I secured all the novelties I could lay hands on, also common market varieties, and having regard for an old favourite of one whose gardening days are long since ended I planted a few Early Yorks. Of the latter a buyer remarked, "The women folk never lay them long-hearted Cabbage down again." The fact is the Early York, in proportion to bulk, is the heaviest Cabbage we have. I was sadly annoyed at the seed generally being so mixed. Daniel's Defiance was the exception. It is a noble market marrow Cabbage, and, what I like, requires no earthing-up. I had a fine square of summer Cauliflowers from seed of my own sowing, though hereabouts the rain of this very wet season for Cauliflowers was some ten days too long in coming, and I spoiled the lot, or at least all the best of them. For exhibition I have tied-up Cauliflowers for years, but perhaps never previously till the hearts were two-thirds grown. In this instance I tied them up when they were little larger than buttons, and before I noticed the evil the inside leaves had turned yellow and the hearts were bursting through between. Of Autumn Giant I had twelve hundred from an eighteen-penny packet of seed, and not a dozen went blind. But nearly the first two hundred "went" for all that—they went to the pigs. They came green and seeded. The remainder, however, were beautiful, and I have one in the vinery now seeding that was 11 inches across. I have a fancy that uripae seed is the cause of so many of this noble Cauliflower having no heart, and perhaps these green ones are attributable to carelessness in selecting the stock. Mr. Stickley, who took such pains in selecting his Red Cabbage and who grew them so well, was for many years a near neighbour, hence in this neighbourhood we boast of our Red Cabbage; sow them all in the spring with the Cauliflowers under glass or nearly so, and by the middle of August they average in weight some 8 or 9 lbs., and I have seen our cottagers exhibit some this autumn really a remarkable size.

The Onion maggot is a pest. I rather fancied our Editors were incredulous when a while ago I recommended "boiling" the crop: Now the fact is Onions will stand having water poured over them when little off the boil, and maggot life can stand nothing of the kind. If taken in time hot water poured over the bed will prevent the maggot going further by simply killing them, but if the maggot has got so far as to have eaten itself overhead, then do what you like the crop is done for.

It may or may not be news, but the fact is our colliers down here are possessed of quite a craze after Leeks. I know of even 2d. a-piece being offered for some when in the seed pan, and every village has, independent of other shows, its Leek show. When criticised by our London dailies the poor pitman is always accompanied by his fighting dog. It is a libel. As a specimen of these shows I should be so glad would you copy the following report from our local paper; I think it will prove that the Durham pitman's taste lies in quite a commendable direction. Just to finish, pray allow me to state that considering my remarks on manuring at the commencement of my jottings I have avoided particularising about the separate cultivation of the vegetables spoken of. In the report I wish it to be particularly noticed that all the prizes are comprised of useful household articles, which I like; every time you see them they create pleasure. Somehow you lose sight of money; it has wings, and ere you are aware it is flown.—J. WITHER-SPON, *Red Rose Vineries, Chester-le-Street.*

P.S.—PELTON FELL LEEK SHOW.—A Leek Show was held at the house of Mr. Thomas Mason's, Hot Hills, Pelton Fell, when a number of prizes were offered for competition. There was a good number of entries, and the Leeks shown received high commendation from all the visitors, as well as the professional gentlemen who judged them. The following were the successful competitors, and the prizes awarded to each:—For best three Leeks, Thomas Batey, a cruet stand; 2nd, John Ferguson, a coffee pot; 3rd, John Studham, a teapot; 4th, Robert Appleton, a teapot; 5th, William Wishart, a cruet stand; 6th, John Johnson, half dozen knives and forks; 7th, John Barker, half-dozen table spoons; 8th, George Armin, pair of salts; 9th, Thomas Mason, jun., pair of candlesticks; 10th, Luke Mason, pair of butter knives; 11th, Joseph Wrangham, bread board and knife; 12th, James Dixon, pair of candlesticks; 13th, John English, a pocket knife; 14, Matthew Wass,

a set of brushes; 15th, John Hollison, a cruet stand; 16th, Thomas Cook, pair of candlesticks; 17, Edward Barker, a water pot; 18th, Robert Purvis, a spittoon; 19th, Edward Pearson, a butter pot.

OUR BORDER FLOWERS—AMARYLLIDS.

THE Snowflakes are a small family, but that does not detract from their beauty or their service to us in many ways and under a variety of circumstances. In a late *Journal* a well-deserved word of commendation was spoken for our old favourites, the border flowers, by one who was visiting a place where those had been cast aside for the red, white, and blue, but the old favourites were being again reinstated. Snowflakes are spring, summer, and autumn-flowering plants, but the family we notice is the Summer Snowflake, *Leucojum aestivum*, said to be derived from *lukos*, white, and *ion*, a Violet, having reference to the colour and fragrance of the flower—a charming name for a charming subject. It is said by some to be a native plant, but I doubt the authority. It is perfectly hardy in our climate and may be well naturalised, but I have not had the pleasure of meeting with it away from the habitation of man. It thrives well in most soils and situations, and is increased by division after growth has been matured. They are capital plants for most shady borders and sides of walks in wood or wilderness.

Less known is *Leucojum pulchellum*; it has much the same appearance, but flowers earlier in the spring, and is a very useful border plant. Closely allied we have *Acis autumnalis*, or the Autumn Snowflake, named after *Acis*, a Sicilian shepherd. Being from Sicily it is a delicate subject in our climate. It is of dwarf slender habit, and requires care to succeed with it. It should have a moderately warm dry situation; sandy loam, peat, grit, or charcoal, with thorough drainage will meet its requirements. There are others of this charming group. *A. grandiflorus*, *A. trichophyllus*, and *A. roseus* are seldom seen, but are worthy of extensive cultivation: when once established they will take care of themselves.

Then we have the *Erinosema*, from *er*, the spring, and *osme*, to smell, one of if not the most charming of all our spring flowers. This, the Spring Snowflake, is right wherever you like to put it. Six or eight bulbs in a 6-inch pot repeated as often as you please for indoor work in early spring are among the most beautiful of early flowers, and for beds and borders they are all that can be desired. Instead of being planted by the dozen they are worthy of being planted by the thousand. This is not a plant of yesterday, having been among us since 1596. It should have a place in all gardens. At present, comparatively speaking, it is a rarity. *E. multiplex* and *E. carpathica* need looking up now that we are in want of early bloomers in the spring; they are early-flowering spring plants. To succeed with them they require attention.

The rarer kinds are increased by parting the bulbs when they have matured their growth; when established they are best left alone. They last many years, repaying any amount of care bestowed on them. There is some confusion in the families above named. Why they are separated I am not able to say; no doubt there is a cause, or they would have been left quietly under the name of *Leucojum*, or further back still with the old authors under *Galanthus*.—VERITAS.

ROSE CUTTINGS.

OBSERVING in the *Journal* of October 25th a method of propagating Tea Roses on their own roots, and that July and August are the best time for inserting the cuttings, I beg to suggest a simple method which will answer well this present month of November—a method which I have found to exceed any other way; a method which I think will suit all, as glass is not brought into use.

I have come to the conclusion after many experiments, that the best system of propagating Roses on their own roots, whether they be Tea or Hybrid Perpetuals is, about the middle of this month to have a west-aspect border; dig or rake it down fine; then prepare the cuttings, choosing the most ripened shoots. Make the cuttings, say 5 or 7 inches long, have a sharp knife for the purpose. In cutting the end to be inserted make the cut through the base of the joint, trim the rest of the buds off, leaving the cuttings with two or three buds above ground. Have a spade and short line; nick or make a small trench; place about an eighth of an inch of sand at the bottom, then insert your cuttings, taking care to make the soil

firm to them. The sand will induce the cuttings to callus soon. Then they will remain in this dormant state until spring, when they will take root, and will make good plants during the summer.—H. T.

RAVENSWORTH CASTLE.

RAVENSWORTH CASTLE, the seat of the Earl of Ravensworth, is about three miles and a half from Newcastle-on-Tyne. The name Ravensworth, according to Hutchinson, is derived from the Saxon word *raffen*, meaning the standard of Denmark; but Surtees shows the name Raven enters into numerous Saxon words, and in some instances it may be derived from the haunts of the bird itself. Ravensworth Castle, observes Hutchinson, "was a castle long before any records now extant, as there is no license to embattle and kernellate this house found in the archives of the bishop, though of every other house in the county there is that evidence." The Castle stands on the side of a hill sloping gradually towards the river Team. In the time of the Boyntons and Gascoignes it seems to have consisted of four oblong square towers connected by a regular curtain, and probably included a keep or central tower. In 1808 the whole of the old house was taken down, with the exception of two corresponding towers. The erection of the present noble edifice was commenced when the old building was partly removed on a plan of the light Gothic, designed by Nash, and consists of a selection of castle architecture of various periods skilfully brought together. The Castle has three principal fronts; the south one is very handsome, consisting of turrets and façades, some of which are covered with Ivy and have a pleasing effect. A handsome conservatory, built from a plan of one of the family, terminates the west front. Opposite to this on a raised terrace is a handsome fountain; the water falls into a basin from eight leopards' heads, while a powerful jet plays from the centre. The stones used in the building are freestone, and were procured from an adjoining quarry. The north side constitutes the entrance to the Castle, and is very pretty and effective.

The Castle is sheltered on the north by a fine forest of Oaks and evergreens. The south aspect consists of at least three hundred acres of rich meadow land, with here and there trees planted for effect, and it stretches for a mile and a half towards the pretty village of Lamesley, which is beautifully wooded. At the south entrance to the park stands a beautiful lodge in a style corresponding with the Castle. There are several other lodges, all neat and handsome structures, comfortable for the inmates as well as ornamental.

On the private road to Newcastle stands a cross, the common tradition of which is that when Newcastle was visited with a plague in the reign of Queen Elizabeth the people from the country here sold and bartered for their provisions. The cross is a plain shaft on an octagonal pedestal. The manor of Ravensworth contains a valuable and extensive field of coal. The first waggon-ways and the second steam engine used in the north belonged to the Liddells, the family name of the Ravensworth family.

The gardens lie north of the Castle; at the entrance is the Superintendent's house, which is a neat and tasteful structure, and partly overlooks the gardens. The principal range of glass, which is nearly semicircular, is about 430 feet long and 18 feet broad, and is divided into nine houses or compartments, which are all lean-to's. The first, a greenhouse, contains some very fine specimen plants, foremost of which may be mentioned two *Erica Bothwellianus* 5 feet through and 3 feet high; also a fine plant of *Phenocoma prolifera* Barnesii. *Aphelexis macrantha* is fine and healthy. Here is also a *Genetyllis tulipifera*, which is set with flower buds at each joint, and a fine *Chorozema spinosa*, also two *Lisandra macranthas*, which Mr. Moulton is decidedly partial to for the autumn; he starts this plant in heat, and gradually inures it to greenhouse treatment. Here was also *Cassia corymbosa*, a mass of golden yellow, which Mr. Moulton manages to flower six months of the year in the following simple manner:—In February the plant is pruned back to about two eyes of the young wood; it is then potted in a compost of about two parts loam and one part peat, to which is added sufficient sand to make it sharp. He then starts it in heat, say a vinery or intermediate stove, from whence it is removed to a greenhouse to prepare it for being placed outside in the first or second week of June where it does not get the sun too strong; this makes it firm and short-jointed. Here are also some fine *Camellias*, such as the Marchioness of Exeter, rose colour, between

5 and 6 feet high, and also two plants of *Hendersoni* equally as good; these plants were perfect in symmetry, and well laden with buds. Mr. Moulton makes it his practice to leave but one bud to each shoot; by this means he secures an annual supply of *Camellias*. At the east end of this house is planted a noteworthy plant of *Lapageria rosea*, covering about 108 square feet of glass, and its charming flowers were gracefully hanging down in clusters. The second house is a late Peach house, with a Moorpark Apricot on the back wall. The Peaches are *Violette Hâtive* and *Royal George*; while the Nectarines are *Violette Hâtive* and *Pitmaston Orange*. Both trees were ripening their wood well, and were free from red spider. In this house were two fine *Camellias* of Mrs. Abbey Wilder, a white, and also one of *Lowi* and *Chandleri elegans*, equally as good as those mentioned. The third is a late vineery of about 28 feet long, and consists of *Lady Downe's*, *Black Alicante*, and *Trebbiano*. This was an even house of *Grapes* well coloured, and bunches weighing about 2 lbs. each. Mr. Moulton considers *Lady Downe's* and *West's St. Peter's* better varieties than *Black Alicante* for late work, for he thinks the best attribute *Alicante* possesses is its charming colour when placed on the table. In this house were two fine specimen *Azaleas* and three large *Ixoras coccinea superba*, which are to be here for a time for want of better accommodation.

The fourth house is a vineery, which principally contains *Black Alicante* and *Black Hamburgh Grapes*, of which remained some fine examples of both varieties. In this house were some fine specimen *Azaleas*, for Mr. Moulton does not place *Camellias* and *Azaleas* outside after they have done blooming; they are removed into the vineeries and peacheries, and allowed to remain there to make their growth. A liberal and frequent use of the syringe is applied at all times, and thus the houses are kept free from insects. These houses so far are simply heated with flues.

The fifth house is a plant stove with a plunging bed in one end heated by pipes. Here we saw a fine young plant of *Maranta Veitchii* with thirteen large leaves, also some fine *Musas* and large *Stephanotis*, with two or three *Bougainvillea glabras* good, and an *Ixora Williamsi* about 3 feet through and 2½ feet high. Noticeable also were some fine plants of *Eucharis amazonica* in about 10 or 12-inch pots. One of them had nine spikes of flowers with six flowers on each spike. This was the third time of flowering this year. The mode of treatment adopted consists in giving a rest after flowering, then plunging it in bottom heat for a time, after which it invariably throws up flower. Those plants have remained in their pots for some years now. On the side stages here were a quantity of *Poinsettias*, *Justicias*, *Euphorbia jacquiniiflora*, *Eranthemum pulchellum*, and other winter-flowering plants.

The sixth division is a fruiting Pine stove with a plunging bed and hot-water pipes in it. The varieties were principally *Montserrat* and *Providence*. One or two fruits of the latter were swelling off, and would, perhaps, average 5 or 6 lbs. each. At the end of this house were *Cucumbers* in pots, and, plunged in the hotbed and trained up to the glass for the winter, they looked very healthy and strong. On a water tank here, which is covered with a stone slab, was a splendid plant of *Lælia anceps*, throwing up seven flower spikes. This plant remains here all the year round, and the cool bottom seems to suit it admirably. Here were also two fine plants of *Anthurium Schertzerianum*.

The seventh house is an early vineery. The varieties are principally *Black Hamburgh* and *Muscat of Alexandria*. Here were some plants of *Salvia patens* and a fine specimen of *Azalea Roi Leopold* 5 feet through, also other good plants. The eighth house is a second Peach house, and consists of the same varieties as the former. Here were some fine *Bouvardias*, which are grown in a cool frame during the summer, also some large *Camellias*, a good *Eriostemon* or two, and a sturdy specimen of *Erica Aitoniana superba*. The ninth and last house is a late vineery. The varieties are principally *Lady Downe's*, *Mrs. Pince*, and *Black Hamburgh*. The *Grapes* were not quite ripe at the time of my visit, October 4th, although strong fire heat had been applied for some time. Here cuttings are struck of *Begonia Sedeni* in the spring, and planted out against the stonework in front of the houses or against any bare wall, and they flower profusely during the summer. On the Vine borders were seven hundred *Strawberry* pots; the varieties are *President* and *Garibaldi*, which were strong and healthy.

At the end of this range is another entrance to the kitchen garden, to the right of which is a Peach house or lean-to for

early work about 52 feet long, with a division in the centre; it is heated with flues. The lights had been off during the summer, and were just put on at the time of my visit to prepare for early forcing. Near the Peach house is a span-roof stove about 21 feet by 14, with a plunging bed in the centre. In this house were specimen plants of *Allamanda nobilis* and *Dipladenia amabilis*, with the young shoots trained near to the glass, so as to procure all the sun possible; also good *Crotons*, a *Cissus discolor* or two, and a plant of *Dendrobium nobile* about 4 feet through. On the side stage above the pipes were some fine plants of *Calanthe vestita*, with leaves as large as *Phaius grandiflora*. Close to this house are two ranges of pits for forcing *Potatoes*, *Cucumbers*, &c., in, and also one for successional *Pines*. Near to this is a span-roof warm greenhouse of about 24 feet by 12 feet. In it were some fine plants of *Sericographis Ghiesbreghtiana*. Mr. Moulton places this charming plant outside during the summer. On the opposite side of the walk is the *Erica* house, a half-spanned low house, heated with a flow and return pipe. It is a very homely structure about 20 feet long and 12 feet broad, yet in it were the following specimens, all remarkably healthy and possessing good symmetry—plants which any cultivator may feel justly proud of:—*Ericas Austiniana*, *Irbyana*, *Marnockiana ampliata*, *ollula*, *tricolor Hoffordii*, *obovata umbellata*, and *Jacksoni*. These were an even lot of about 3½ feet through and 2½ feet high; but the crowning plant of all was a *retorta major*, 4 feet by 4. This was a real gem. Leaving here you come to the fruiting Pine pit, about 26 feet long and 18 feet wide. The plants were principally *Queens*, strong and healthy, and are expected to throw up next spring for summer use.

The kitchen garden consists of about four acres. The soil is a heavy cold clay; there is therefore great difficulty in the procuring a choice supply of vegetables all the year round. Mr. Moulton experienced great difficulty in growing *Asparagus*, but by adopting the following plan has insured success. When planting he raises the beds about 1 foot higher than the alleys. By this means the plants when young do not go off; and when they get older and are in a state for more nourishment, these alleys are filled up gradually with leaf soil. He also prefers sowing to planting. A quantity of *Asparagus* is annually forced; this is generally done in a late vineery or Peach house, Mr. Moulton believing in strong bottom heat and plenty of air for flavour.

Peas were growing after *Celery*; the varieties *McLean's Gem*, *Ne Plus Ultra* and *Champion of England*, *G. F. Wilson* and *Hair's Dwarf Mammoth*. These are sown in the order mentioned. Onions were not a heavy crop, an unusual thing at *Ravensthorpe*, and many have thick necks, which is the case generally in the north this year. The favourite Cauliflower is *Walcheren*, which is grown late and early. There are also quantities of *Brussels Sprouts*, *Savoys*, *Cabbages*, *Coleworts* and *Broccoli*; the varieties of this last vegetable are *Snow's Early Purple Cape*, *Danvers Pink*, *Carter's Champion*, *Wilcoxe's White*, *Alexandra* and *Late Mammoth*, which generally come in the order mentioned. The soil is too cold for *Potatoes*; they are grown in raised drills. By this means they come earlier and finer.

The walls are covered with *Peaches*, *Nectarines*, and *Apricots*. The former fruits are the same as those mentioned in the houses with the addition of the *Barrington Peach*, which is deservedly a great favourite here. Fires are applied to these walls when the blossom buds begin to expand, and are continued to the end of May; the trees are also well covered with *frigi domo* netting. The *Pears* that do best are *Marie Louise*, *Glou Morceau*, and *Winter Nellis*; the *Plums* are *Victoria*, *Princess of Wales*, *Kirke's*, and *Green Gages*. On the borders are dwarf pyramid *Apples* and *Pears* on the *Paradise* and *Quince* stocks respectively. The varieties are of *Apples* *Lord Suffield*, *Wellington*, *New Hawthornden*, *Cellini*, *Cox's Orange Pippin*, and *Kerry Pippin*; while the *Pears* are *Louise Bonne of Jersey*, *Beurré d'Amanlis*, *Beurré Diel*, and *Williams' Bon Chrétien*. Parsley is grown on the borders for winter, neatly hooped over and matted on the approach of snow. A quantity of *Seakale* is grown and forced much in the same manner as the market gardeners force it near London. It is taken up every autumn; all cuttings are taken off and thrown into a heap till the spring; all eyes are rubbed off but one, and the cuttings are planted in rich ground previously well prepared, and splendid plants are produced for forcing by the autumn.

Near the kitchen garden is a small roseery, which was quite refreshing to the eye after being so long lingering and admiring the culinary part of these gardens. Many *Roses* were in full

bloom; conspicuous amongst them was *Souvenir de la Malmaison*, which is an admirable autumn Rose. We next entered a small walled enclosure oblong in form, which was formerly used as a plunge bath, and now answers the purpose of holding the supply of water for these gardens. This is a charming sequestered spot. Corners and nooks are artistically filled with Ferns, with just sufficient flowering plants to brighten this cheerful yet solitary spot. Here are also large plants of *Osmunda regalis* close down to the water's edge.

Leaving here "fresh scenes of beauty burst upon the view." A little westward is perhaps the prettiest of all the scenery of Ravensworth, for here is a charming lake, small, irregular in figure and outline, and literally clothed to the water's edge with large *Rhododendrons*, some of them 20 feet or more in diameter. These have a huge background of large forest trees. Truly this place must be gorgeous in the month of May.

Near to this lake are two or three common Yews, about 20 feet high, sugar-loaf in shape, and not more than 3 or 4 feet wide at the base—they are most imposing. *Cryptomeria japonica* is 30 feet high, well furnished to the base. Retracing our steps eastward toward the Castle we come to another lake which is not so imposing as the former, and from here the view (fig. 76), of the Castle is obtained. Adjoining the massive pile is the conservatory; it is, like most structures of its kind, not adapted to the successful culture of plants. Camellias are planted-out. Against the walls were *Tacsonia insignis*, *Lapageria rosea*, and *Acacia Riceana*, also Orange trees, *Fuchsias*, and the usual summer-flowering plants, this place being especially reserved for the Azaleas and Camellias during the winter. There is a division in the north end, which is connected with the picture gallery by glass doors. The gallery is 101 feet long, and this part of the conservatory is occupied by

Fig. 76.—RAVENSWORTH CASTLE.

Ferns, with a large *Dicksonia antarctica* for a background, having a head 21 feet through and a trunk of 12 feet high. This Fern has made about twenty fronds this year. It came here in a small pot about sixteen years ago, and at present its fronds measure about 2½ feet across. Here is *Alsophila excelsa*, *Woodwardia radicans*, *Todea superba*, *Asplenium flaccidum*, and *Scolopendrium crispum*. These Ferns seem to revel here in their solitude, and are fit appendages to a picture gallery. They have a gradual slope towards the glass doors of the gallery, and from which they must have a fine appearance by gaslight.

The south terrace front is about 100 yards long and 23 yards broad, with an abutment jutting-out in the centre. In the abutment a little bedding-out is done, and at the end of the terrace, in a small border close to the Castle, a few flowering plants are employed. On the wall is *Clematis Jackmani*, Ivy, and Roses, and at the east end is a splendid *Magnolia*. Leaving the Castle here on the road to the Superintendent's house is a little more bedding-out, just sufficient to relieve the surrounding subjects of turf and shrubs. The pleasure grounds consist of about fifty acres. The following Pinuses are scattered over them:—*Pinus monticola*, 30 feet high, grafted; *Taxodium sempervirens*, 30 feet; *Abies Albertiana*, as thriving as a Larch, 60 feet high; and *Cedrus atlantica*, 25 feet high.

In concluding these remarks it becomes a duty to congratulate Mr. Moulton on the efficient manner in which every depart-

ment is conducted. The local circumstances of soil and climate he successfully grapples with, although not possessing many of the modern improvements in the glass structures. He has lived here for thirty years, and speaks in the highest terms possible of the kindness he has at all times received from the Earl of Ravensworth. For twenty years Mr. Moulton has exhibited at the principal north country shows with great success, and for a long time was the principal support of the Newcastle Horticultural and Botanical Society; and even now that this Society is on a firmer basis so as to entice some of the best exhibitors from the south, Mr. Moulton still honourably holds his own, for in the autumn show he took first and second prizes for the three best *Ericas*, and first for the three best flowering plants, and first for table decoration.—J. C. A.

TOMATO OR LOVE APPLE.

THIS, *Solanum lycopersicum* of botanists, is thus noticed by the historian of cultivated fruits:—"It is a native of South America, and in all probability of Mexico, from whence it appears to have been brought by the Spaniards, who, as Barham observes, use it in their sauces and gravies, because the juice, as they say, is as good as any gravy, and so by its richness warms the blood. Dodoens, in his *Pemptades*, published at Antwerp in 1583, described it as growing at that time in the

Fig. 77.—VICK'S CRITERION TOMATO.

continental gardens, and says that its fruit was eaten dressed with pepper, salt, and oil."

It appears according to the "Hortus Kewensis" to have been cultivated in England as early as 1596, and Gerard

mentions it in his work, which was published in 1597, as growing in his garden. Parkinson, whose works were published in 1656, mentions it as being cultivated in England for ornament and curiosity only. For a long time, however, it has been grown

for use as well as for ornament, and is increasing in esteem yearly. In America it is extensively cultivated, and much attention has been given there to the raising of improved varieties. Some of these have already become popular in England, such as Hathaway's Excelsior, The Trophy, and some others, which are remarkable for their smoothness and general good quality.

The engraving which accompanies these notes represents the most recent of the American varieties—namely, Vick's Criterion Tomato, which has been awarded a first-class certificate by the Royal Horticultural Society. This beautiful variety was raised by Mr. James Vick, the well-known seed grower of New York. It is a very prolific well-shaped variety with smooth skin, very distinct in colour, the fruit being of a cornealian red. The seed has been placed in the hands of Messrs. James Carter & Co. for distribution.

PRACTICAL NOTES ON CAMELLIA CULTURE.

BEGINNING with the house. The Camellia being a comparatively hardy evergreen it will succeed, as far as growth and appearance are concerned, in almost any description of house. They do well especially as permanent plants in conservatories, for when not in flower the foliage is ornamental, and other flowering plants can well be arranged about them all through the year. Houses of Camellias may be seen, too, in good condition where there is much more of architectural building about them than would suit many other kinds of plants. Still, to make the best of Camellias there can be no doubt of the ordinary span-roofed house being as well suited to their culture as any kind of structure that can be devised, because such a house can be made to suit all seasons; for in dull seasons the plants will set their buds best in such a house, and if it be a bright summer when the plants are making their growth sufficient shade can easily be applied to keep the foliage from being injured.

The shading, or influence of shade, has a great deal to do with the successful cultivation and blooming of the Camellia. It cannot be said that the Camellia will not thrive as a plant in a shady place in a cool house, but will it flower well? or will the flowers be other than mostly of an inferior character under such circumstances? Numerous instances can be seen where good healthy Camellia plants will not form flower buds in too shady a place; and, besides, the character of many flowers under such circumstances is so different they are scarcely recognisable. The influence of sufficient light is most necessary after the wood is made and the flower buds are forming. It is difficult, no doubt, to regulate shading to a nicety when many other plants require to be attended to; nevertheless, it can be done near enough for practical purposes. Shading, as I have noted, is most required in the early part of summer to keep the foliage, which is then tender, from being scorched; very little of shading is required afterwards, especially during such a summer as the last; but in hot dry summers a little more shading would be beneficial just to keep the foliage from being in any degree "browned."

It is a common plan and effectual in shading to paint the glass roof outside with a liquid made up of churned milk and whiting, the same requiring to be attended to and renewed after thunder showers, which will often wash it off. The only objection, perhaps, that can be advanced against this kind of shade is that when it is on it has to stay on, whereas a canvas rolling shade can be made to suit circumstances; in dull weather it can be rolled up, and in hot put down. In a sunless season the latter shading would be best, and in a bright one the whitewash will answer very well, it having the advantage of economy with it. It might be mentioned that this last season, which was not over-bright, a very thin whitewash was put on a span-roofed house, and now the appearance of the plants for flowering is as good as need be desired. The wash was only put on once when the young wood was being made, allowing the weather to take it off for ripening the wood.

It may be singular to say, though evidently it is quite true, that in some places Camellias do much better than they do in others, the attention given being practically similar. This may be through the bad water or unsuitable soil also of the neighbourhood. If it were in the former case, no doubt the evil could be remedied by securing a sufficient quantity of rain water conserved in large tanks to keep up the supply all through the year; if in the latter, a change of soil is the only remedy.

The soils used in Camellia culture afford a subject that is

often under comment. Sometimes the plants are found doing well wholly in turfy peat, and again they are seen flourishing in yellow loam. As regards the latter case, however, it is not every yellow loam that would be advisable to use for the Camellia. A good soil that will suit the Camellia generally is one composed of two parts of turfy loam and one part of turfy peat, with a slight mixture of sand.

Although the soil used is a very important matter in Camellia culture, perhaps it is not more so than proper and steady attention as regards watering. When the plants are making their growth they should be watered liberally, syringing them also regularly. Still the soil in the pots or in the beds should not be allowed to be sour, and after syringing care must be taken to observe that wetting from the syringe is not a true index of the under-surface soil. After the growth is made syringing should be withdrawn and less watering given, keeping the plants just in a moist condition at the root. The extreme on the one hand of over-watering to injure the roots, and under-watering to dry them up, are the two great evils in the unsuccessful flowering of Camellias.

Whether planted out or grown in pots, Camellias in their flowering season are very ornamental. When planted out it may be said they involve less labour in attention as regards watering than when grown in pots, but then it is necessary to know the condition of the border so as to know how to water provided the soil be of a proper kind. When the plants are in pots they are much more under control, and, excepting the very large plants, perhaps they are better in pots. When Camellias are planted out they are what might be called fixtures, whereas when in pots they can be advanced for early flowering or moved about in the conservatory to suit arrangements of colour, &c., and when well bloomed in pots they give ample satisfaction. There can be no doubt, where planted out, a greater amount of vigour of plant is secured, and perhaps larger blossoms; but for abundance of flowers plants in pots will often be quite equal to those planted out. By having plants in pots, too, the Camellia period can be so much prolonged, which is a great advantage.

A good time for planted-out Camellias to come into flower is about Christmas. By having a few early plants the period of flowering may commence in September. Good plants in pots of *fimbriata alba* are fine conservatory ornaments, and they will flower sooner than could be expected from planted-out specimens; also it may be especially noticed that a few early Camellia specimens coming into flower, say in October or November, last a long time. These as soon as done flowering may be put into heat to bring on in the same way for the succeeding year.

The temperature required for successful cultivation is one easily to be attained, for though Camellias require steady treatment within certain limits, they are not susceptible of injury by a few degrees' difference in temperature usually; sudden changes, however, must be guarded against. A few degrees of frost might bring down the buds, and the same result would probably occur were well-forwarded plants placed suddenly into heat. A temperature of from 40° to 45° in winter, with a little additional heat to the natural summer's warmth, will suit the Camellia well. As regards ventilation, it is surprising how little of this is required for Camellias excepting in very hot weather; but the fact of their growing well in dark and shady places will easily account for this. In winter, for example, they succeed well in houses with scarcely any ventilation, excepting, perhaps, the door open on mild days.

If the Camellias are in robust condition many of the sorts towards the end of the year may require disbudding. If large fine flowers are wanted, one bud on a shoot will be sufficient. Some kinds usually only form one bud at their points, and when in flower they make a very good show; still for ordinary purposes it will be well to reduce on healthy plants the buds to two or three in different stages on each shoot. Disbudding of leaf buds, too, may be adopted to keep the plants in shape instead of using the knife further. It is not good practice to cut-in Camellias too severely if flowering condition of plant is aimed at; when too much cut-in they make wood instead of flower for a year or two.

The best time of the year for potting Camellias is either after they have ceased flowering, before they make their young wood, or after the wood of the season is made and the buds formed. If the plants are short of pot room and well advanced in bud a top-dressing of Standen's manure spread over the surface of the soil will greatly assist the opening of the flowers, and may be better than potting if that operation could not be

done at the right time. Camellia plants in good compost flower well without any artificial manure; Stauden's, however, can be supplied safely in most cases. This mode of manuring, or liquid from the farmyard, is the best for supplying manurial nutriment to the Camellia. In potting, one of the principal and first item to attend to is proper drainage (which is equally important with plants planted out); and when putting the earth round the roots the compost should be made firm; if in pots leave sufficient room on the surface to hold water.

As regards keeping the plants free from vermin, an occasional smoking from tobacco paper will keep down thrips and green fly. If the latter only infest the plants they can be removed by frequent syringing, as they usually only make their appearance in the growing season when syringing is in operation. As refers to other vermin, if the plants are clean to start with there is not much trouble with them; but of late an objectionable insect seems to be making headway in the country, which should, if possible, be kept under and eradicated. In the winter time it causes a great deal of filth about the stems of the plants and leaves; in spring, when the sun shines, it may be best observed moving about the bark like a small brown scale; when the plants are put in heat it grows to a larger size, and ultimately throws off white down resembling the mealy bug. This is the scale in a breeding state, and perhaps the best way to get rid of it is to go over the plants regularly and remove every one in this stage. If this insect makes its appearance in a collection of plants it will soon go over the whole. Painting the hard wood the same as Vines' stems and washing the foliage is not sufficient.

Before Camellias come into flower they look all the better for having their leaves sponged with soap and water; with clean foliage the flowers show to so much better advantage.

It may be remarked that Camellias in pots for winter flowering are not so frequently seen as they deserve to be, and collections of Camellias of various sizes in flower make a splendid show of themselves. Camellia flowers can be had of every desirable hue, and the bud variation in the Camellia is also very interesting.—R. M. A.

ROSE DEVONIENSIS.

In the list of Roses named in the Journal of October 4th, page 265, the name of Curtis is given as the raiser of the Devoniensis, but the time is not stated when the Rose was sent out to the public.

The Rose above named was raised by George Foster, Esq., of Catland House, about a mile distant from the towns of Devonport and Plymouth. I was engaged in the service of Mr. Foster in 1837, and the Rose in question flowered for the first time the following year, and I think I am now the only person living that saw the first or maiden bloom of it.

From Mr. Foster it passed to the firm of Messrs. Lucombe, Pince, & Co., of the Exeter Nurseries, Exeter, and was by them exhibited in London and awarded a Banksian medal by the Royal Horticultural Society. From that fact becoming known the orders for it became so great that a great delay took place before they were executed. I think it was sent out about 1842 or 1843.—JOHN CONNING, *Redhill, Surrey*.

LAMBETH CHRYSANTHEMUM SHOW.

NOVEMBER 12TH, 13TH, AND 14TH.

To organise and support a floral society within a one-mile circle of Horsemonger Gaol might appear to many almost ludicrous, yet such a society exists, and a show was held on Monday last and two following days at the Borough Road Lecture Hall, which was worthy of extensive patronage. In little "toy" houses and dingy back courts the productions for this Show were grown, and amongst the exhibitors were to be found shoemakers, engineers, and policemen, and the result of their endeavours was a most praiseworthy exhibition.

The schedule consisted of thirty-nine classes, all for the encouragement of the Chrysanthemum. A more varied schedule we have scarcely met with, and right well were the classes represented, in fact in some cases the competition was very keen; but the date fixed was a little too early, especially for specimen plants, but the cut blooms taken collectively were above the average, and good stands of incurved, reflexed, Japanese, large-flowering Anemones, Anemone Pompons, and Pompons were staged.

Mr. Wilher was awarded the first prize for twenty-four cut blooms, distinct, with Princess of Wales, Prince of Wales, Guernsey Nugget, Nil Desperandum, Mrs. Dixon, Bella Donna, Beethoven, George Glenney, Lady Talfourd, General Bainbridge,

Lady Hardinge, Antonelli, White Globe, Fingal, Novelty, Miss Mary Morgan, Prince Alfred, Eve, Gloria Mundi, Mrs. Halliburton, Orange Perfection, Lady Slade, and Catherine Talfourd. In the class for six incurved blooms of one variety there were eleven competitors, and the first prize was awarded to a variety named Mr. Bunn, a very fine golden flower. Mr. Summers was awarded the first prize for twelve Japanese varieties in not less than eight sorts, and had very fine blooms of James Salter, Erecta Superba, The Mikado, Garnet, Elaine, The Cossack, Hero of Magdala, and Peter the Great; and Mr. Fill was awarded the first prize for twelve Anemone blooms in not less than eight varieties, with grand examples of Prince of Anemones, Acquisition, Gluck, Louis Bonamy, George Hock, George Sand, Margaret d'Anjou, and Lady Margaret. The same exhibitor was worthily awarded a first prize for three trained standard Pompons, which deserve more than a passing word of praise for their excellence. The varieties were Antonius, Marie Stuart, and Calliope. Other successful exhibitors were Messrs. Halstead, Clark, Truelove, Tracey, Pryer, Addison, and Ball.

Our space will not allow us to give further details, but we must compliment Mr. Summers, the Secretary, for the neatness and general arrangement of the Exhibition. Such uniformity we have never seen before; the stands were all made and painted alike. The names of every variety were plainly written on neatly bordered tickets, and the prize cards were secured at the back of each box. A better arranged show we have never seen.

NOTES AND GLEANINGS.

At a general meeting of the Fellows of the ROYAL HORTICULTURAL SOCIETY, held on the 6th inst., W. Haughton, Esq., in the chair, the following candidates were duly elected Fellows of the Society—viz., Mrs. Charles Carus-Wilson, T. H. Ford, John Gordon, Sir Stuart Hogg, Mrs. Morgan, G. Neilson Tucker, Col. Ravenhill, R.E., W. Hussey Walsh, and Charles Wollaton. James Lewis and Henry Hepburn were also elected guinea members.

THE record of WINTER CUCUMBER CULTURE at Eastnor on page 339 is a type of the sound gardening practice carried on there, but there is much more to be seen at Eastnor than superior fruit culture. The pleasure grounds are extensive, upwards of 100 acres in extent; also beautiful, for they contain hundreds, rather thousands, of handsome Conifers. The Castle is a splendid pile, a pure example of Norman architecture, and the lake in front picturesque. A fine new terrace is being formed near the Castle, conceived with excellent taste and executed in superior style. There are only a few, very few, flower beds in the grounds, and fortunately none on the terrace, for modern bedding would be incongruous associated with the severe grandeur of such a building and its appendages. A place might probably be found at Eastnor for Geraniums, Golden Feather, &c., but beds of such plants on the terrace would impair its dignity and mar, not enhance, its beauty. Eastnor is beautiful without flowers, and is a garden worth a long journey to see at any time, but especially in summer, when the grand old Vine—the glory of the fruit department—is bearing its youthful crop.

WE have received from Rev. F. D. Horner, Kirkby Malzeard, Ripon, a ripe head of seed of the white Arum *CALLA ETHIOPICA*. This specimen ripened under the care of Mr. Hebblethwaite, gardener to G. Serjeantson, Esq., Camphill, Bedale, and when in a fresh state was of a pure lemon colour. It is the first specimen we have seen from Yorkshire.

MESSRS. HARRISON & SONS announce that their eighth annual EXHIBITION OF FARM ROOTS, &c., will take place on the 21st and 22nd inst. in the Market Place, Leicester, when silver cups and other prizes will be awarded for the largest and handsomest roots grown from seed supplied by them. The prize roots will be exhibited in the Seed Warehouse on Saturday, November 24th.

MR. TEBB informs us that he has received a letter of thanks from the Royal Horticultural Society for the PATENT FUMIGATORS which he exhibited at South Kensington on November 6th.

IN our report of the last meeting of the Fruit Committee of the Royal Horticultural Society we mentioned that a cultural commendation was awarded to Mr. Wildsmith for excellent but not quite perfectly coloured bunches of *GROS COLMAN GRAPE*. We have since seen a still finer example of this Grape grown by Mr. Wildsmith. Many of the berries are quite 4 inches in circumference, and are nearly jet black; the quality is also very good, better than we have hitherto

tasted Gros Colman. Mr. Wildsmith would do good service by stating how he grows this Grape so fine and colours it so well. The bunch to which we refer is a masterpiece of superior cultivation.

— WE recently noticed in Mr. Wills's Nursery at Anerley a very distinct new FERN which has been raised by Mr. Bause, who states it as being the result of a cross between *Adiantum trapeziforme* and *A. decorum*, to both of which it bears resemblance, yet it is totally unlike either. Its novelty consists in the pinnae being quite reflexed, as if the plant were asleep; indeed, it might popularly be termed the Sleeping *Adiantum*. It is at the same time free in growth and very elegant. Such kinds as *Adiantums cuneatum*, *decorum*, *scutum*, and *gracillimum* are raised from spores by thousands, and still the demand can scarcely be met. *Dracenas* too command notice, both by their great numbers and excellent condition. The newer varieties are in fine colour, and the older, such as *terminalis*, are represented by thousands of handsome plants. They are worthy of note and inspection.

— MESSRS. CARTER & CO.'S METROPOLITAN ROOT SHOW in the Agricultural Hall, Islington, is the largest that has ever been held there. The gallery, which is a quarter of a mile in length, surrounding the Hall is occupied with farm and garden produce of exceptionally good quality. Mangold Wurtzels owing to the cold season are perhaps not quite so numerous nor fine as last year; but the Swedes and Turnips exceed both in numbers and quality any previous display that has been arranged in the building; Kohl-rabi is very good, Cabbages immense, and Potatoes, Onions, and Carrots excellent. The collections of vegetables contain admirable examples of nearly everything in season: especially superior are the Turnips—Smart's Monsetal, Early Snowball, and White Stone; Autumn Giant Cauliflowers, Carter's Perfection Brussels Sprouts, and Leeks. There are also capital dishes of Hathaway's Excelsior Tomatoes. The prizes were not awarded when we left the building.

— No decorative plants in Covent Garden Market are now more attractive than ROMAN HYACINTHS. Five bulbs are grown in a 48-sized pot, and the effect of the pure white masses of elegant bells is very pleasing. These miniature Hyacinths are increasing in popularity yearly on account of their earliness and usefulness. They are as valuable for cutting for bouquets, &c., as they are acceptable for decorative purposes in pots.

— ALTHOUGH the present autumn has not been particularly favourable for the opening of CHRYSANTHEMUMS, yet an excellent display is provided at the Crystal Palace. Mr. Thomson has, amidst his multifarious duties, contrived to grow two thousand plants, and has grown them well. They are in exuberant health—admirable in foliage and blooms. The new variety, Golden Empress of India, is likely to prove a real acquisition. Many blooms of it are extremely fine, and the colour—soft osany yellow—is very pleasing. *Jardin des Plantes* and its bronze variety are splendid; as also are White Globe, Lord Derby, Alfred Salter, Prince Alfred, Pink Perfection, and White Venus. The Beverlys have passed their best. They have been excellent. Cassandra—white, also fading—is noteworthy as one of the best of its class; and the popular trio—Mrs. G. Rundle, Mrs. Dixon, and George Glenny—are remarkably fine. Amongst the reflexed varieties, many of which are so valuable for decorative purposes, *Hermoine* and its golden variety, Dr. Sharp, Julie Lagravère, Barbara, Progne, Beethoven, Sam Slick, and Maréchal Ducoc are in admirable condition. The Japanese varieties are represented by James Salter, Elaine, very fine; Cry Kung, rosy purple, excellent; and the still deeper and newer variety *Gloire de Toulouse*. The plants are arranged at the front of the great orchestra, and are an important feature of the attractions of the Palace.

— MR. ROBERTS, gardener, Charleville Forest, Ireland, has won, according to the *Irish Farmer's Gazette*, the honour of having grown the HEAVIEST BUNCH OF BLACK GRAPES yet produced. The bunch alluded to was cut the other day on occasion of the rejoicings which took place at Charleville Forest on Lady Emily Bury attaining her majority. It was fine in shape, berry, and finish, and weighed 23 lbs. 2 ozs. The breadth across the shoulders measured 22 inches, the length from the footstalk to the point of the bunch a little over 2 feet. We thought it a pity that this noble bunch was not sent to South Kensington by Mr. Roberts, but the difficulty of getting it there without the bloom being spoiled in transit no doubt deterred him from forwarding it. It would no doubt have caused a sensation there, and been justly regarded as the most gigantic

and best proportioned bunch of black Grapes yet produced in British gardens. The Vine which produced this monster bunch and the more moderate monsters of last year has been about four years planted. It is growing in a lean-to house. The soil of the border is sound and simple. Mr. Roberts eschews complicated composts, having faith in the wholesome and satisfying nourishment afforded by the loam obtained from the surface of the Charleville deer park. Mr. Roberts regards his famous Vine as a particular and superior variety of Gros Guillaume.

— MR. J. MUIR writes to "The Gardener" that PARSLEY which has been thinned has proved a failure, while the plants in rows which have not been thinned have grown luxuriantly. Mr. Muir further observes that Carrots very often go off similar to Parsley, and next year he will sow a few rows thinly and not thin the plants; and also try a bed or two of Onions in the same way, as Mr. Pettigrew of Cardiff Castle always sows his Onion seed thinly, never thins the plants, and always secures splendid heavy crops.

NOTES ON VILLA AND SUBURBAN GARDENING.

Now that the leaves have mostly fallen from deciduous trees no time should be lost in collecting them. The trouble that leaves give while falling, and the untidiness gardens generally present at that time, are more than balanced by the usefulness of the leaves for mixing with manure for hotbeds. They are valuable also for covering over Rhubarb and Seakale. Their heating power is not so violent as stable manure and they are more lasting; if collected when dry and laid in a large heap they will keep a long time. Those collected in moist weather should be used first. Lawns should have a thorough sweeping and rolling to render them fresh, smooth, and neat. In places where the grass has grown more than is usual at this season of the year owing to the mild weather, the mowing machine may be used on a dry day. It will be well to set the machine a trifle higher than usual, and when the mowing is finished give the machine a good cleaning and oiling before laying it by for the winter. Pull out or otherwise destroy weeds in walks, and frequently roll the gravel with a heavy roller, which will not only make the walks pleasant at the present time, but will prevent the wet from penetrating, and the frost from raising them up.

In the kitchen garden the usual winter operations, such as digging and trenching, may be proceeded with, and if early Peas and Beans are much in request a sowing of each may be made on a south border. If the winter is mild there will be a gain of a week or two in gathering, but unless gardens possess the advantage of a warm and dry soil it is almost useless to attempt sowing at present. Sow the seed thicker than recommended for spring sowing, and in shallow rows. Chopped furze placed over the seed will prevent the ravages of mice, or red-leaving the seed is said to answer the same purpose. Some cultivators lightly steep the seed in paraffin. A layer of coal ashes placed over the rows on the top of the soil is also a great protector during sharp frost. William I. Pea and Carter's First Crop are the sorts suitable for present sowing, and of Beans the Early Longpod. Cauliflowers under hand-lights and frames must be constantly looked over. With us the slugs have been very busy; we have caught numbers, and have given the plants a good dusting of lime and soot. Make good all vacancies and expose the plants night and day unless severe frost should set in, when they should be covered up every evening. Globe Artichokes should be protected around the stems with litter or common bracken, and Jerusalem Artichokes should have the stems cut down and a layer of a similar nature scattered over them to prevent frost from penetrating the soil. Parsnips are always better flavoured when left in the ground until wanted, and a layer of bracken or litter placed over the bed will permit the roots being dug-up during severe frost.

FRUIT TREES.—It is often a matter of grave consideration for owners of small gardens to select the best and most prolific-bearing sorts from the vast number of varieties in cultivation. The present is the best time for planting, and the following varieties are recommended for their hardiness, free-bearing, and excellent table or culinary qualities:—Culinary Apples—Keswick Codlin, one of the earliest and a sure bearer; the fruit may be used for tarts in a very young state. Lord Suffield, a large-sized early sort and an immense bearer. Young trees may be seen loaded with fruit when not more than two or three years old. Cellini, an excellent cooking Apple. The tree is a very free bearer and hardy, its late blossoming generally secures a crop; it is useful also as a dessert fruit, and is in season during October. Beauty of Kent, a large Apple of excellent quality and a very free bearer. We have gathered fruit from this variety weighing 18 ozs. In season from October till January. Hawthornden, an early and abundant bearer. Wellington, or Dumeau's Seedling, a very heavy bearer and the fruit handsome, and keeps well all through the winter; a very valuable variety.

Dessert Apples—Irish Peach is one of the best early kinds grown; it is a beautiful Apple of rich flavour; the tree is a free bearer, ripe the first week in August. Kerry Pippin, a free bearing early kind of fine aromatic flavour; in use during September and October. Cox's Orange Pippin is, taking into consideration all its good qualities, undoubtedly the finest of all dessert fruits. The tree is a great bearer, and the fruit is of good size and for flavour is unsurpassed. Where there is only room for one tree to be grown it should be Cox's Orange Pippin. King of the Pippins is a constant bearer; the fruit is of good quality, and is in season during the early part of winter. Court-Pendu-Plat is a valuable late dessert Apple, and the tree is an abundant bearer; it is in use during December and the spring months.

Of Pears Jargonelle is a good early variety, but will not keep long after being ripe. Williams' Bon Chr tien is a very rich-flavoured Pear, a constant bearer, and suitable either for dwarfs or standards. If the fruit of this excellent Pear is gathered at two or three different times the season can be prolonged; ripe in September. Louise Bonne of Jersey is an immense cropper, of splendid quality, ripe during October. Marie Louise, a well-known excellent variety, ripe during October and November. Beurr  Diel, a large-sized free-bearing variety, ripe in November. Beurr  Bachelier, a hardy, large, handsome, and excellent Pear, ripe towards the close of the year; and if late Pears are required, Josephine de Malines and Winter Nelis may be added.

Of Plums Green Gage, Transparent Gage, and Coe's Golden Drop for dessert; and for cooking, Prince of Wales, Victoria, and Pond's Seedling. White Magnum Bonum and Orleans are also useful varieties.

May Duke, Napoleon Bizarreau, and Governor Wood are excellent Cherries, and the Morello is useful for preserving and for tarts. Three good Peaches for a wall are Royal George, Grosse Mignonne, and Noblesse—these are all free bearers and of superior quality; and three good Nectarines are Lord Napier, Violette H tive, and Pitmaston Orange.

In planting make the stations of sufficient size to allow the roots to be spread out in their natural position, placing the trees about the same depth as they were in the nursery, which will be easily seen by the appearance of the bark. Carefully place the finest and best soil around the fibres, and if the soil is light slightly treading it will make it firm. It is necessary to place stakes to all newly planted fruit trees, and care must be taken to prevent the stakes from rubbing the bark and causing wounds. A piece of matting or cloth can be placed between the tree and stake, which if made secure with tarred string will prevent the trees from being blown about, and will enable them to become established the sooner.—J. W. MOORMAN.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

HARDY FRUIT GARDEN.

ALL out-of-doors operations may be performed amongst fruit trees with some degree of pleasure when the weather is so mild as it has been during the last week or two. Pruning and nailing wall trees has been proceeded with, not that much of either is required, but it is always necessary to look over the trees. When the shreds are very much decayed all over the tree, it is best to remove all of them and to re-arrange the entire tree. This sometimes requires to be done when the branches become weak and are thinly placed at the base of the tree. When this has been the case we have been able to cut-out some of the weak branches at the base altogether, and then bring the others down to take their place. The centres of the trees are usually very easily filled-up with young wood. The skilful cultivator will manage it so that nearly the whole of the wall is covered with bearing wood. Everyone knows the tendency that fruit trees have to extend the radius of bearing wood from their base, leaving stems destitute alike of either wood or leaf buds. No amount of skilful management can alter the nature of the trees or altogether counteract the effects of this tendency, but whenever it is possible (as it often is), young bearing wood should be trained over the main stems, not only to hide them but also to increase the area of bearing wood. Trees trained on what gardeners call the fan system are most liable to show a number of naked stems; by this method of training we fancy is the best for Peaches, Nectarines, Apricots, Plum and Cherry trees. Apple and Pear trees are usually trained on what may be termed horizontal cordons—that is, an upright main stem with horizontal branches 9 inches apart. By constant summer pinching or pruning the spurs are apt to become crowded with useless wood. This must be thinned-out now, leaving the most prominent buds nearest the main stem. For the largest branches it is best to use tarred twine to fasten them to the wall, shreds are not strong enough. A stout nail should be driven firmly into the wall, then tie the twine to the head of the nail, fasten it round the branch and draw it in tightly, allowing, however, a little room for expansion.

Vines may now be pruned and nailed to the wall, and we would still insist on the importance of frequently renewing the

old wood by training-up young rods. If previous directions have been followed this will have been done, and all that is required now will be to cut-out the old and exhausted wood and to shorten the young growths. It is not implied by saying this that all old wood that has borne fruit should be cut out, the young wood of this year will be the old wood at next pruning time. What we would do is this: no wood would be allowed on a 6-foot wall older than two years, on a 9-foot wall than three years, and on a 12-foot wall than four years. This treatment is especially applicable to the Royal Muscadine or similar Vines best adapted for cultivation out of doors. The lateral growths should not be too closely cut-back to the main stem. We usually allow three eyes, and one of the growths is almost sure to have a bunch of fruit; the other two may be removed.

PINE HOUSES.

We have been cutting fruit of Charlotte Rothschild and Smooth-leaved Cayenne, but were not able to keep the temperature high enough, consequently the fruit, though juicy, was not of superior quality. It will not do at this time of the year to ripen the fruit in a lower temperature than 65 , if it ranges between that and 70  all the better. The utmost caution is required in watering. In careful hands manure water benefits Pines very much, but if injudiciously applied much damage results to the fruit. If the plants are freely supplied with manure water up to the time of the fruit colouring, in all probability it will be black at the core. It is absolutely necessary to leave off using manure water about the time the fruit takes its second swelling. If the soil is moderately moist water must be withheld from the time the fruit shows signs of colouring. In our beds, where the pots are not far from the pipes, there is more danger of the roots becoming dry than there is when they are plunged in deep beds of moist leaves where the heat is kept up by fermentation.

Suckers that are just established in the small pots in which they were potted early in autumn or late in summer are kept in a temperature of 55 ; they do not receive much water. They might be grown on a little faster if necessary, but usually we have not room to pot them until May.

We have heard a little of new Pines within the last two or three years, but it will be some time before anything will beat the sorts we have grown for many years. The most recent of ours is the Charlotte Rothschild, but all points considered, although a most noble fruit, it is not equal to Smooth-leaved Cayenne. It is generally understood that there is a good and bad strain of the Cayenne. We have had the fruits decay before they were ripe, but this has generally happened in spring when fierce sun has scalded the fruit, coming suddenly upon it after the dull dark days of winter; we usually just lay a sheet of newspaper over the crown to protect the fruits from injury. Is it not possible that this weakness in the Smooth-leaved Cayenne has led people to believe that there are two varieties? The Queen holds the same position amongst Pines that Black Harzburgh holds amongst Grapes, and it is even now more valuable owing to the fact that nearly all the St. Michael's Pines are Cayennes, and these being imported in quantity at certain seasons very much depreciate the value of home-grown fruit. Good Queens are not only valuable for home consumption, but they always command a high price in the market independent of any glut from abroad. If it is intended to pot any plants in February the soil for this purpose ought to be put in a dry place, as it will not be in good condition for potting if exposed to the wet during winter. Good, sound, moderately clayey loam from an old common where Brackens grow freely answers well for Pines.

GREENHOUSE AND CONSERVATORY.

If a greenhouse or conservatory is to be furnished in first-class style it must contain specimens well grown of the finest Cape and New Holland plants, but these will not make an efficient display alone. At the present time the different varieties of Zonal Pelargoniums make a most effective display, and small plants are more useful than large specimens, as by growing a number of plants in 6-inch pots greater variety is obtained, and the variety is now almost endless. There are pure white flowers, and others blush with pink centres, salmon colours of various shades, rose and pink, red, scarlet, and deep crimson. Then how easy it is to grow them! The cuttings are inserted about the end of March, one in the centre of a small 60-sized pot. The pots are placed on a shelf near the glass in the greenhouse, where they receive plenty of air, but not much water until they commence growing, when they are more freely watered. In April they are placed in a cold frame. In May the plants are shifted into small 48's, and in July into 6-inch pots. From the end of May until the end of September the plants are placed out of doors, and after taking them into the house they are supplied with manure water at every alternate watering. In order to have a strong healthy bloom in November the plants must not be allowed to exhaust themselves by bearing flower trusses in summer; these must be removed before the flowers open. The best potting material is turfy loam four parts, decayed manure one part, and one part of leaf soil,

sand to be added if necessary. The withered flowers must be removed as often as possible, and the stages and paths be kept clean.

Stage or show Pelargoniums, including the fancy class, have now filled their pots with roots and require to be repotted. We have usually potted them early in February, and from small plants in 6 and 7-inch pots we obtain a long and continuous bloom, more so than is the case with those potted now. Autumn potting produces a mass of bloom all at once rather than a long succession of trusses. Mr. Ward of Leyton, who exhibited this class of plants most successfully, used to pot in October those intended for the first shows, and in November for the latest bloom. Those who follow his example and obtain the same results will have no reason to complain.

Cinerarias and Calceolarias are now growing freely, and the growths must be tied-out as they require it. The thick leathery leaves should be hanging over the sides of the pots or hiding the surface of the ground. Fumigate with tobacco smoke until not a single green fly can be found on any of the plants.

Chrysanthemums are, as a rule, late this year, but we have fine blooms of many of the sorts now fully expanded. The flowers on specimen plants are, as a rule, the latest. Mrs. Geo. Rundle and its golden sports, also Aurea Multiflora, Prince of Wales, &c., will soon be in flower. The single blooms and also the Japanese varieties promise to be very fine with us. The object now is to keep the blooms in perfection as long as possible, and to this end no more water should be spilled in the house than what runs through the drainage of the pots in watering.—J. DOUGLAS.

TRADE CATALOGUES RECEIVED.

Kelway & Son, Royal Nurseries, Langport, Somerset.—*Catalogue of Gladioli.*

Jonathan Booth, Florist, Pole Lane, Failsforth, near Manchester.—*Catalogue of Carnations and Picotees, Pinks and Auriculas.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

BACK NUMBERS (R. P.).—You can have all the numbers you refer to.

CORONILLA INFESTED WITH SCALE (*A Lady*).—Make a strong solution of Fowler's insecticide and dip the plant in it or syringe, repeating the operation three or four times if necessary. Afterwards syringe well with clean water.

REPOTTING CYTISUS RACEMOSUS (*Idem*).—It will do no harm to take your large plants out of pots and replant them in tubs now if you particularly wish to do so, otherwise it is preferable to do this after the flowers have faded.

TEA ROSES (*E. T. H.*).—All Tea Roses flower freely on their own roots when the plants are well cultivated.

POPLARS FOR A SCREEN (*A. B.*).—The Black Italian Poplar is the most rapid-growing of all the Poplars, and answers well in a town. Plant them 12 feet apart with a view to the ultimate removal of every alternate tree. The answer to another correspondent last week about *Taxonia Van-Volkemi* is exactly what you require.

AMARYLLIS AFTER FLOWERING (*Sambo*).—Gradually reduce the quantity of water, giving very little during winter, but do not suffer the soil to become dust dry, and repot in March.

CULTURE OF HERBACEOUS CALCEOLARIAS (*A Lover of the Calcey*).—No artificial heat is required except to exclude frost. Keep your plants upon a light airy shelf near the glass. Repot from time to time as soon as the roots touch the sides of the pots in soil consisting of equal parts of loam and old rich manure, with about a fourth part each of sand and pounded charcoal, taking especial care to use plenty of drainage. Attend well to watering, and fumigate with tobacco paper to keep down aphides. For large specimens it is necessary to nip out the centre of the plant to induce it to form a strong lateral growth. Cease repotting as soon as the flower stem begins growing, and then substitute coddling water or sewage for the clear water. By close attention to this simple formula you may grow plants for exhibition with success and derive much pleasure from the work, for no plant with which we are acquainted rewards one better for care and attention than does this.

PROPAGATION OF HARDY HERBACEOUS PERENNIALS (*J. B.*).—It is much too late in the season for propagation by cuttings now; you may, however, increase your stock of many kinds by division. We may remind you that plants of this class are not generally used for spring bedding. To have your beds green throughout winter and gay with flowers in spring you should plant them immediately with such hardy annuals as *Silene pendula*, *Saponaria calabrica*, *Myosotis*, *Limnæthes*, *Iberis*, and *Nemophila*, and with them such perennials as *Pansies*, *Coincys*, *Primroses*, and *Hepaticas*.

TRIMMING A HOLLY HEDGE (*Inquirer*).—Prune your Holly forthwith. The present time is a suitable one for making a rockery.

PAMPAS GRASS NOT FLOWERING (*A. E. A.*).—A cold and wet situation is unsuitable for Pampas Grass. During the last four or five years we have planted it experimentally upon elevated exposed situations, in nooks and corners of shrubberies, upon the upper slopes of a valley with perfect success, the plants growing strongly and bearing a profusion of spikes annually, some of them at the present time being fully 10 feet high; but upon the lower slopes and in the bottom of the valley, as well as by the margin of a pond, the plants, like yours, grow well but have few spikes. It is therefore

obvious that an elevated well drained position is necessary for it. We intend trying the effect of putting some of those in the valley upon mounds raised some 2 or 3 feet above the common level, and would advise you to give the plan a trial, but by no means destroy any of the leafage as you propose.

BLACK HAMBURG GRAPE (*T. F. H.*).—We think the specimen good and full flavoured. Ventilate freely and have little moisture in the air.

STRAWBERRY PLANTING (*A. Dumbell*).—The best way to plant them is in rows, allowing a distance of 2 feet between each plant. *Adiantum palmatum* was sent out in the spring of the present year. It can now be obtained from any nurseryman at a reasonable price.

MANAGEMENT OF A GRAPE VINE (*W. E. B.*).—It has grown strong enough to bear fruit next year, and the best time to prune it is when the leaves fall off. Cut the young wood back to within 3 feet of the base of the rafters. Dress the border after you have pruned the Vines. Sow the Mustard and Cress thickly, and you will have no difficulty in racking it in a neat manner. Wash it before using, but it is not washed before it is placed into baskets for sale. What you see in Covent Garden is not raised from Mustard seed but from Rape.

WINTER TREATMENT OF VINES (*M. A. M.*).—Prune the Vines when the leaves fall, wash and dress the rods immediately after, then tie them neatly in a horizontal position along the front of the house. It is not necessary to do this, but the canes are more out of the way when thus tied down.

CLIMBERS FOR SOUTH FRONT OF A DWELLING HOUSE (*H. I.*).—You have already named a good selection. Try Tea Rose *Maréchal Niel*, and *Rosa bracteata* (Single White Macarney). *Magnolia grandiflora* (Exmouth variety) has a noble effect in such a position. An Apple orchard may succeed in the position you name.

PLUMS FOR MARKET (*C. S.*).—Rivers' Early Prolific, Victoria, and Gisborne's. You might give Mitchellson's and Prince of Wales a trial. The best two Strawberries are British Queen and Sir Charles Napier. The largest-fruited Strawberry is Cockscomb.

LARVE OF INSECT (*G. H. B.*).—We do not recognise it, but the best way to get rid of such pests is by hand-picking.

WIRING GARDEN WALLS FOR FRUIT TREES (*B. K. L.*).—The wires should be 9 inches apart, the eyes should be about 4 feet apart, or if the wire is very stout 6 feet. The distance apart for the trees should be from 15 to 24 feet. The higher the wall the further the trees should be apart. Do not use any manure round the roots at planting. The ground should be moderately rich, and some maiden loam should be placed in immediate contact with the roots.

COMPOST FOR AND WIDTH OF VINE BORDER (*G. S.*).—The depth of soil should be 3 feet. The width for the first planting may be 6 feet outside and as much inside. The border should be made the whole length of the house.

TREATMENT OF VINES IN POTS (*A. Duncan*).—The most prominent and largest eyes are always those nearest the top. About 6 feet of cane is a good length to allow for fruiting. Cut the planting canes back to about 2 feet, and when they start into growth rub off all the eyes except those nearest the ground, and train up the number of young rods you require. If you only want one rod select the best, and take care of that; but it is as well to train two, as an accident may happen to the first.

ROMAN HYACINTHS NOT DOING WELL (*W. L.*).—The treatment you gave them is quite right. We advise you to place them now in gentle heat; they may do better than you suppose. Probably by this time the rest of the bulbs have formed roots. It is no use trying to force them until roots are formed. A gummy substance does exude from the crown of these bulbs.

HARDY CYPRIPEDEUMS (*Idem*).—It is a mistake to keep them quite dry in winter. This would account for the crown becoming soft. They do well with us, and we give enough water to cause moss to remain green on the surface of the pots. They are placed in a shady part of the greenhouse.

CARNATIONS (*England*).—We cannot recommend any florist. Refer to our advertising columns.

HEATING GREENHOUSE (*Dilemma*).—We do not approve of the plan. The best way is to have a supply cistern and have a small air pipe at the highest point of the pipes, which is usually that farthest removed from the boiler. We object to fixing the pipe in the side of a saddle boiler as on your plan. The pipe ought to be close to the boiler, but it should be fixed in the return pipe.

DEFINITION OF A NEW ROSE (*Midland Counties*).—A new Rose is one of recent introduction; but if a class is made for them at Rose shows it is usual to say "New sorts introduced in 1875-6," or three years may be given to select from instead of two, but always naming the year before that in which the schedule was printed. If you want to purchase the best Roses of recent introduction we advise you to apply to some of the principal Rose-growers. Say how many you want and leave the selection to them.

SUPPORTS FOR ROSE TREES (*M. E. D.*).—Iron stakes, whether painted or galvanised, are not injurious. Those galvanised are to be preferred.

NEW ROSES.—At page 362, column 1, *Capitaine Christy* should be stated to be a cross between *La France* and *Baronne de Rothschild*. In the notice of *Duchesse de Vallombrosa* the Rose referred to should also be *Baronne de Rothschild*.

GORSE (*S. B.*).—There is no separate work on its uses, but there is a lengthy detail in the "Farmers' Encyclopedia." Apply to Messrs. Sutton or to Messrs. Carter for grass seeds suitable to your sandy soil.

"FERN WORLD."—Mr. Heath informs us that the misplacement of the plates we noticed does not occur in other copies.

ADIANTUM FARLEYENSE.—Mrs. G. Hodder, Spring Well, Clapham Common, has sent us a frond having spores. We have frequently seen spores on this Fern, but have not known any plants come true when raised from them.

NAME OF SHRUB (*C. B. E.*).—It seems to be a species of *Prunus*, but we cannot name it from a single spray with leaves only.

SEA-WEED AS A MANURE (*J. L.*).—Spread it over the ground and dig it in whilst fresh before planting the intended crop.

NAMES OF FRUITS (*W. Jacob*).—Figue de Naples. (*E. T.*).—The Apples are all good varieties. The green one is *Gloria Mundi*. It was raised in America. Though not high-flavoured it is a very good culinary Apple. The full bearing will depend upon the trees rooting freely and being properly cultivated. (*F. H., Enfield*).—2, Hawthornden; 3, Stirling Castle; 4, Court Pendu Plat; 5, Court of Wick. (*H. G.*).—1, Tower of Glamis; 2, Winter Hawthornden; 3, Red Doyenne. (*H. E. Monk*).—1, Ross Nonpareil; 2, Cornish Gilliflower; 3, Surrey Flat Cap; 4, Adams' Pearmain; 5, Autumn Bergamot; 6, Winter Greening.

NAMES OF PLANTS (S. L.).—*Physalis edulis*, Cape Gooseberry. It requires to be preserved from frost, but should be in the open border during the summer. (G. W. W.).—It seems to be *Chrysanthemum leucanthemum*, but the small bit was crushed. You may cut off the Orange and Lemon trees now. (O. F. J.).—We think it is *Lycopodium cespitosum*, but the specimen is bad.

POULTRY, BEE, AND PIGEON CHRONICLE.

CRYSTAL PALACE POULTRY SHOW.

ONCE more the great poultry contest has come round. Other shows have their ups and downs, but the old-established ones, and especially the Palace, continue to be annual successes. Even the conflict of shows which has this year taken place in and near the metropolis, to the detriment alike of birds and of the fancy, has not affected the entries at the Palace. They are upwards of four thousand, and their quality seems yearly to increase with the number. Some slight alterations there are in the arrangement of pens, and the numbers begin on the reverse side of the building to that on which they have of later years, but as a whole all looks the same as in former years. Most of the same well-known faces are to be seen, and one could fancy one had been asleep since some former November, and on waking had found all in its old position.

Dorkings, as always, head the list. Old dark cocks only number eight. First is a moderately dark bird, square and good in shape, but indifferent in comb; second a large bird but not remarkable; third we thought long on the legs and white in lobes. The hens are a large and better class. First-and-cup is a magnificent bird, one of the finest we have ever seen, rich and good in colour; second a long and large bird too, of the old-fashioned lighter colour; third nice in colour and fair in size, but has a swollen foot. Mr. Parlett's very highly commended hen looks like the winner of last year. The cockerels are a large and good class. Mr. Beachey's champion is a wonderful young bird, dark in colour and immense in frame. We do not care to see so much white in tail and ear, and one of his centre toes is curved; second is a bird of the same type, and rather shorter in legs; third apparently a young bird. We liked his good white feet, though not his white lobes. Fourth a sprightly well-shaped bird with a good comb; fifth a lumpy short-legged bird. Among the very highly commended Mr. Burnell has a fine bird, Mr. Peel one of thorough Dorking shape, and Mr. Cresswell one with good dark colour and really white feet. The pullets are not at all equal to the cockerels in merit. The cup pullet is a very large Dark bird, but her fifth claws are not well put on; second a very fair Dark bird; third large but sooty in feet. This sootiness seems a disfigurement much on the increase, and is worse in pullets than cockerels. Fourth large in frame, but not good in feet; fifth a bird promising to grow much. Silver-Greys are above the average, but we must confess that the judging sorely puzzled us, and in some cases the very worst birds seemed to win. The cup cock is a grand bird and deserved his position. He is evidently the cockerel shown by Mr. Cresswell last year and claimed at Birmingham. Second has much white in his breast and one centre toe cut short; third very small and yellow, and about the worst in the class. We cannot say much for the first hen; she contrasts very unfavourably with Mr. Burnell's very highly commended bird next to her, a magnificent hen, worthy of a cup; second a fair bird with a bad comb; third a nice hen. In cockerels the cup goes to a now well known bird which we need not describe; second is a good bird all round, but not striking; third a small, neat, silvery bird. In pullets the first winner is as well known as her brother; second a square bird; third a very young pullet, promising to be immense. Cuckoos are still shown in pairs. They do not progress in number or quality. The first pair are well marked and well shaped; second are large but longer on leg, and the cock is bad in comb; third are a pretty pair, very dark. Whites are progressing much. First-and-cup is a grand cockerel, good in comb and shape; second the Oxford cup-winner, as white as ever but minus his sickles, or he must have been first again; third a promising but slightly coarse bird. In hens the winner is enormous, though we do not admire her so much as her owner's third-prize bird, the cup hen of various former years; second a fine-framed hen barely through the moult.

[The remainder of our report was not received when going to press.]

POULTRY.

DORKINGS.—Coloured.—Cock.—1, Rev. E. Bartrum. 2, R. Gladstone. 3, T. Breden. Hen.—Cup and *chc*, F. Parlett. 2 and 4, T. C. Burnell. 3, Dr. E. Snell. Cockerel.—Cup and 2, R. W. Beachey. 3, H. JUDGES.—*Poultry and Pigeons:* Mr. G. A. Crewe, Etwell, and Mr. E. Hutton, Padsey. *Canaries:* Mr. J. Athersuch, Coventry.

CIRENCESTER POULTRY SHOW.

THIS Exhibition was held in the Corn Hall, under very distinguished patronage. The entries in the poultry and Pigeon classes amounted to 678. Most of the classes were well filled. The Judges were Messrs. Hewitt and Nicholls for the poultry, and Mr. Jones for the Pigeons. The £55s. cup for the best pen in the Show fell to Mr. E. Burrell's pen of Crêves, and the same exhibitor won with his Buff Cochins the cup for third best pen of poultry in the Show, while the £33s. cup was awarded to Mr. C. Bloodworth's pen of Silver Polands. The silver medal for the best pen of Waterfowl was won by Mr. Hedge's Aylesbury Ducks, and the cup for best Pigeon in the Show, exclusive of Magpies, went to Mr. Herrieff's Pouter, a Black Magpie of Mr. S. Salter winning the Magpies' £33s. piece of plate.

Dorkings were fifteen pens in number, and a moderate pen of Darks won first prize. Light *Brahmas* had seventeen entries, and the quality was on the whole fairly good. The Darks did not muster nearly so well. We believe last year they were as weak in numbers. The winning pens were, however, good, and did not give the Judge much trouble to choose them. In *Cochins* Bufts made thirteen pens, and the first winners were a pretty pair of Buff chickens; the second and third were also chickens of the year. In the next class very good adult Whites came in first among eleven pens. Whites, again, were third, and Partridges and Whites of Messrs. Clatworthy and Buckmaster were highly commended. In *Spanish* a pretty pair of chickens were first, and the class of nine pens was fairly good. The *Leghorns* made two fairly good classes, the winning White chickens being well shown and very smart in carriage. *Game* had three classes, and the quality was good. The first Black Reds very smart in carriage, and in fine feather. Mr. Warde's birds, too, were well shown, and in good condition. *Hamburgs* also had three classes, and all were filled well. The Pencilled made the largest display. The first in Spangles went to good Gold, and the winning Blacks were fresh-looking and bright. The *Malays* were excellent, and the first-prize pen were in good condition and large. All the *French* met in one large class, where Crêves of wonderfully good quality were first. Crêves, too, were again second, and good *Hondans* third. *Polands* were an extraordinarily good class, and every pen was noticed. Superb Silvers were first. They were in good feather, and should do well at shows to come. The second were cheap at £44s.; and third again were very good Silvers. Messrs. Norwood's, Unsworth's, and Burrell's were all good pens. The Variety class had eight entries, of which a pair of Langshans were commended. We fancy that a Judge in noticing this breed in a variety class makes himself a believer in the breed, for did he only consider them inferior Black Cochins, they should have been passed over for being in the wrong class. We commend this to the notice of the Judges. The winning Black Red Bantams were good, as was the pen of Piles which won in the next class. In the variety Bantam class *Laed* were first and second, and Blacks third. The *Waterfowl* were good classes, though the Aylesbury, as has been the case of late, were a very small class, while the variety Duck class was extremely meritorious, and each pen won a card at the hands of the Judge.

POULTRY.—DORKINGS.—1, Miss M. Boote. 2, J. Paxton. 3, F. P. Bulley. **BRAHMAS.**—*Light.*—1, T. A. Dean. 2, J. Turner. 3, T. Smith. *Dark.*—1, E. Pritchard. 2, H. Lingwood. 3, J. S. Tainton. **COCHINS.**—*Cinnamon and Buff.*—1 and Cup, E. Burrell. 2, W. Paxton. 3, Rev. H. J. Borrow. *Any other variety.*—1, J. Turner. 2, E. Pennohal. 3, Miss H. Williams. **SPANGLES.**—1, H. Blower. 2, J. Newick. 3, J. Aldridge. **LEGHORNS.**—*Brown.*—1, T. Reeves. 2, E. S. Hill. 3, Messrs. Bradbury. *White.*—1, R. Waugh. 2, A. Kitchin. 3, Messrs. Bradbury. **GAME.**—*Black-breasted.*—1, Hon. and Rev. F. G. Dutton. 2, W. T. Garne. 3, T. D. B. Rawlins. *Brown-breasted.*—1, F. Warde. 2, J. Cock. 3, T. Mason. *Any other variety.*—1, F. Warde. 2, E. Vinwood. 3, Miss M. Boote. *vhc.* F. Edwards. **HAMBURGS.**—*Spangled.*—1, T. Blakeman. 2, J. Carr. 3, F. Edwards. *vhc.* J. Jackson. *Gold.*—1, R. Pickles. 2, J. Carr. 3, J. Abraham. *vhc.* Mrs. Arabin (3). **SELLING CLASS.**—1, J. Robinson. 2, W. Radmore. 3, E. Martin. 4, E. H. Sweeting. 5, E. Hawkins.

JUDGES.—Mr. W. A. Blakston, Sunderland; Mr. E. Bemrose, Derby; Mr. F. W. Wilson.

INDOOR RABBIT HUTCHES.

THE outdoor Rabbit hutch is a comparatively simple structure, but there are many contrivances for inside hutches which tend to make them somewhat intricate. For the more hardy Rabbits outside hutches are advisable, but some of the delicate breeds, such as Lops, require more warmth and regularity of temperature than can be guaranteed in an outdoor hutch in this country.

In size the indoor hutch should not be less than 2 feet 6 inches long, 15 inches deep, and 10 inches high, and for Rabbits that are of unusual size it is of course necessary to have the hutches made considerably larger. The bottom of the hutch should be covered with metal or a slab, for the wet will sink into wood, and especially where there is any artificial heat a very unpleasant smell is emitted, which is far from being healthy. This kind of floor would not do for the Rabbits to stand on, as it would cause colds and sore feet. Hence it is necessary to raise the actual floor an inch above it. The best way is to make a wooden slab-frame-floor which will, if properly managed, keep the hutch sufficiently dry and clean. A wire frame floor will also keep the hutch very clean and sweet, but the wire is too hard for the feet, and sore hocks will be sure to be the result. The spars should be about three-quarters of an inch across, and rather less than that distance apart, perhaps half an inch. The wood should be of a hard nature, and pine should not be used as it has too great a tendency to absorption. As, however, it is not the cheapest kind of wood there is, this caution is probably hardly necessary. Oak would be the best, but it is of course too expensive. These slabs should be planed very smooth, and the edges should be shaved off a little so as to enable the waste to pass through easily. The great danger is that the Rabbits' legs will get between the slabs and be broken, but if the width of space does not exceed half an inch there can be but little danger of that. The false floor should be placed about an inch above the slate or metal floor so that the wet will not rise. This floor should be made the size only of the open compartment, the dormitory, which should always be closed until the doe is far advanced in pregnancy, being provided only with a wooden floor, which is the warmest. The dormitory should be about a foot long, and extend the full depth of the hutch. In case the Rabbits are of a small kind 10 inches will be sufficient, but it is important that while making the room large enough for the Rabbit to turn round in, it should not be too large, or it will not be warm. The whole of the front of it should be covered with a dark wooden door, which should open sideways and away from the centre of the hutch. The partition should not be fixed in, but should be fitted between two grooves. A circular hole about 18 inches in circumference should be cut in it near the back portion of the hutch, for the Rabbits to pass through. A few tacks driven into the edges well knocked home so as to keep them from catching the Rabbits' skins will prevent or at any rate check gnawing. A small door will be necessary to cover this to keep the doe out until nesting time has begun. If the circular piece that has been taken out has been kept it may be used. A small hinge may be fixed on the top, and a button on the bottom, or it may be fixed entirely by buttons. In this latter case the door can be taken away altogether, and is perhaps the best plan, as when fastened by a hinge the door may get shut up accidentally, in which case the young may be neglected owing to their mother being unable to get to them. For the large room a door that will admit light and air will be necessary. For Lop breeding a door of the following description will be found to answer well. The groundwork should be three-quarter-inch wood. Along the top a strip of wire about 2 inches wide should be fixed so as to afford ventilation. Then to give light a piece of glass—circular is the prettiest, but square will do—should be fixed as a kind of window in the centre. The frame should be made to fit tight at the sides and bottom, but a little loose at the top, leaving a space of about a quarter of an inch. This will give ventilation, and at the same time avoid draughts. The frame should be fixed with two hinges and fastened by a small bolt or lock.

Another very good front, if the hutch is not intended solely for Lops, may be made in a much more simple manner. Make a frame the size of the opening of good inch wood, about 2 inches wide, the corners being well dovetailed together. Cover this with a strong framework of iron netting, such as can be bought for about 6d. a yard at any ironmonger's, or strong iron bars may be fixed downwards about 1½ inch apart into the two frames. This latter operation is a very tedious one, and but little is gained by it, especially as the hutch being intended for inside use only will not be subjected to such rough treatment as the outdoor ones. For all practical purposes the common aviary wire will answer every purpose, and is cheaper and more easily applied than the bars. It should be carefully fixed to the frame by means of rivets, which can be purchased with the wire. If only nails are used the wire will be constantly coming off and giving trouble, besides giving the inmates a mode of very dangerous egress, which would very likely end in a broken head or two.

A few holes should be drilled in the bottom of the hutch near the back, through which the wet will be able to run, besides which they will enable a good swilling to be given to the floor sometimes, and let the water run off easily. A slip is sometimes taken out along the back end, but this is hardly to be recommended, as it is sometimes the cause of a draught. A small hayrack will be found useful in a hutch, and one of a suitable size can easily be made by any fancier.—G.E.A.

CHLOROFORMING BEES.

Last autumn I saw one of my neighbours (a farmer) very busy in his bee garden, and found that he was destroying a certain number of stocks with sulphur. This autumn he agreed to let me take the honey for him. On the 28th of September I waited upon him with one of Pettitt's ten-bar hives and some chloroform and commenced operations about 7 p.m., upon three straw skeps, giving each hive 1 drachm of chloroform. Last year he destroyed six. After waiting a few minutes I shook out all the stupefied bees on to newspaper. The bees from the three stocks I put into the bar hive, filling it a third full as well as I could see, and carried it home a quarter of a mile, placing it on a stand having a south-west aspect. I then filled one of Pettitt's feeding troughs holding a pint of syrup, and placed it on the crown board.

The bees commenced feeding next morning, and a week's beautiful weather supervening they were very busy each day, and have continued so to the present time. I have given them 36 lbs. of syrup made from 24 lbs. of loaf sugar, costing 4½d. per pound. The hive is now nearly full of beautiful comb and very weighty; I have therefore discontinued feeding and secured them for the winter from wet and cold. By this means I have not only saved the lives of thousands of our industrious little friends, but have added to my apiary another large colony at the very small cost of 9s. I suppose the bees destroyed two out of the three queens placed in the hive.

Hoping these lines may induce other apirians to try chloroform with a similar success when driving is not convenient must be my apology for writing.—H. C.

OUR LETTER BOX.

POULTRY FOR PROFIT (*A Struggling Clerk*).—Keep a Coloured Dorking cock and six Dark Brahma hens.

COCKBURN'S TAIL (*A. Z.*).—We know of no mode of curing a tail that is carried on one side. There is a spinal defect probably. For Ducks there is no food more nourishing than barley meal and Indian meal.

BEE-KEEPING (*Ligurian*).—"Bee-keeping for the Many." You can have it from our office if you enclose five postage stamps with your address.

REMARKS.

- 7th.—Warm wet morning, warm all day; fine afternoon and evening.
8th.—Slight fog in morning, very dark 9 to 9.30 A.M.; fine and pleasant afterwards.
9th.—Wet all day, heavy rain at times; high wind in afternoon.
10th.—Early part of morning fine; hail and heavy shower at 11.15 A.M., and showers afterwards, with occasional sunshine.
11th.—Thunder and lightning about 4.30 A.M.; fine till 9 A.M., then wet and very violent wind, especially after 3 p.m.
12th.—Barometer reached its minimum (29.693 in.) at midnight; at 0.15 A.M. there was very heavy rain and the gale suddenly ceased; morning bright, but afternoon dull with shower.
13th.—Foggy and misty except in afternoon.
The weather continues mild, and the daily maximum temperature remarkably uniform; during the past thirteen days it has not been less than 52.8° (on 11th) or more than 58.4° (on 6th). Very heavy gale on Sunday evening.—G. J. SIMONS.

COVENT GARDEN MARKET.—NOVEMBER 14.

TRADE keeps very quiet, scarcely anything doing. First-class samples of Apples are in demand. Pine Apples from the Azores are now making their appearance, home-grown fruit being very much depressed in consequence. Cobs are quiet.

From observations taken near London during forty-three years, the average day temperature of the week is 47.9°; and its night temperature 33.5°.

CHERRIES AS ESPALIERS.

F all the fruits of the garden Cherries are perhaps the most unsatisfactory. The trees may grow freely, blossom freely, and fruit freely, yet the harvest of fruit is often a barren one owing to the depredations of birds. I am not now writing of Cherry districts where trees are grown by the acre, and where there is much more fruit than the birds can eat, but of ordinary gardens where there is perhaps a dozen blackbirds and thrushes to one Cherry tree. In that case it is not difficult to decide where the Cherries will go, for unless effectual steps are taken preventing them the birds will have nearly every one. That has been my experience. From the dozen fine trees in the orchard under my charge I have reaped little beyond vexation and annoyance, for Cherries I could secure but few, owing to what some call "pets," but which I (during the fruit season) regard as pests—the birds. The loss of the crop was the more annoying, since I was frequently reminded that Cherries were the "favourite fruit of the family"—the reverse of "good news" to the family's gardener. To cover the few large trees with nets was impracticable, and there was no room on the walls for Cherry trees. It then became a question, since Cherries must be had, whether to plant trees and train them in the bush or pyramid form, or whether to plant and train them as espaliers. I had an inclination for the latter, my employer rather preferring the former mode of culture. The result was a compromise, and both systems were adopted. That is many years ago, and many excellent crops have been gathered from both sets of trees; but those trees which have given the most fruit with the least trouble have been the espaliers.

So admirably are Cherries adapted for this mode of culture, so well do the trees bear, so attractive do they look both when blossoming and fruiting, and, especially, so easily can the fruit be protected from birds, that it is a little surprising that espalier Cherry trees are not as frequently seen as espalier Apple trees—not so numerous, of course, but yet represented in every garden which is considered well furnished for meeting the requirements of an opulent family. Yet we seldom find a row or rows of espalier Cherries.

I know only one other mode of growing Cherries that is at all comparable (leaving walls out of the question) to growing them as espaliers and training their branches horizontally, and that is training them to strained wire fences on the diagonal-cordon system. I have not had much experience with this mode of culture, yet I have had sufficient to prove its worth, and were I now called upon to furnish a garden with trees I should certainly have a long stretch of diagonal-cordon Cherry trees. It is the quickest of all modes of producing a "hedge," affords the greatest variety of sorts in a given space, and enables crops of fruit being perfected which cannot be surpassed by any other means. Yet while I should make

due provision for carrying out this system of Cherry culture I should not ignore the value of the old-fashioned horizontally-trained espaliers, for the trees on this plan when established will, I believe, last for generations, and would, I think, although I am not certain on that point, continue in health longer than the much more restricted diagonal cordons.

A point of importance in essaying the espalier mode of culture with Cherry trees is not to have the wires of the fence too close together. The first espalier fence that I had made for Cherries had the wires strained 8 inches apart, but that, in the case of many varieties, proved much too close, and after a time every alternate branch had to be removed, to the great benefit of the trees and crops. The simplest and the best rule of guidance for determining the proper distances for training the branches of fruit trees is to take note of the length of the leaves during summer, and then adopt the principle carried out with rows of Peas—namely, that the same distance should be allowed between the rows as the Peas grow in height; so with fruit trees, the same (or a little greater) distance should be allowed between the branches as the leaves grow in length. The spurs then receive light and air, which are essential to fruitfulness; whereas if the leaves of one branch are allowed to overlap and shade the next, bold fruitful spurs cannot be produced. That applies to all fruit trees, but to none with greater force than the Cherries, and barrenness of these trees is more contributed to by overcrowding than by any other mistake in culture.

Many varieties of Cherries have foliage a foot in length, therefore when the branches are trained horizontally they should be fully that distance apart. That is a good distance for such sorts as the Duke section, while for the Black Hearts and Bigarreus 15 inches apart is not too much for straining the wires.

I am not a believer in the orthodox height of 4 feet for fruit-tree fences. I cannot see any good reason for limiting a row of espaliers to that height when 2 feet more can be added without occupying an inch more ground—2 feet of clear gain I call it, and that in 100 yards length means a great increase of fruit. I do not, however—at least in the case of Cherries—advocate a greater height than 6 feet, because they could not then be so conveniently protected from birds, but for Apples, and Pears I have had good evidence that wire fences 9 feet in height are relatively more profitable than lower espaliers.

Protection of the Cherries from birds is an important point in the management of the trees. All the labour of growing the trees and the cost of supporting them is spent in vain if the pets or pests, as the case may be, are not kept from the fruit: and it is in this matter that I have found the value of espaliers. A bush can be netted, but at the best I have always felt the operation as bungling as it is bundling; fastening and unfastening every time a dish of fruit has to be gathered is no joke when other and urgent work on all sides is waiting to be done. But with espaliers the work of protecting is comparatively easy. Here is the plan: Erect a rough framework over a hedge of Cherries by

inserting some stout poles or battens at intervals of the length, or nearly so, of roofing laths—"rock lats," my old handy man calls them. Let the uprights be $2\frac{1}{2}$ feet from the base of the trees slanting to a foot from the hedge at the top, or rather a little above the top, to secure head room. Secure the tops of the uprights together by cross pieces; now from upright to upright fasten the long light roofing laths, and the skeleton is complete and ready for the net. I have always employed old fish nets, which are both cheap and strong, and I have had no difficulty in obtaining them 18 feet wide. These placed over the framework before the fruit shows colour remain there until it is gathered. The birds are thus baffled, no loss of time occurs in netting and unnetting daily, and Cherry-picking becomes a pleasure.

Now that the time of fruit-tree planting has arrived, and since Cherries are scarce in so many gardens and birds numerous, it may be opportune, perhaps, to mention what I conceive to be the best method of growing this much-esteemed fruit; at any rate if any cultivator can propound a better plan—one more easy, certain, and enjoyable, I shall be glad to hear of it. Morellos do excellently as espaliers, and require little or no protection from birds; at least our birds do not appear to like them.—A NORTHERN GARDENER.

ROSE SHOWS.

WHY DO NOT ROSE SHOWS PAY? CAN ROSE SHOWS BE MADE TO PAY?

THESE questions are often in people's mouths, and engage interest and amuse many besides rosarians, and as I believe them to be questions for the purse-string-holding public to have a voice in, though, as I intend to show, by no means to answer, kindly open the columns of the Rose Journal to a fair discussion and better understanding than now appears to exist.

As one of the public I have always had a fancy for Rose shows, and rejoice to know that I am by no means singular in this respect. Ladies young and ladies not quite young vow Rose shows to be their pet exhibitions. Most men of refined tastes and the least capacity for quiet enjoyment affect them, and yet Rose shows are not sufficiently popular, with hardly an exception, to keep a balance on the right side. Our modern Jupiter is aware of this feeling, and published to the world last July how consistently it went with the times, by reporting in three lines and a half the event of the Great National Rose Show in St. James' Hall, at the foot of a paragraph detailing at length the proceeding of two general London exhibitions. It is easy to say, "Do not be in a hurry; give the public good permanent Rose shows and they are certain to pay. Does not a good article always create and keep-up a market?" Has this been the case as yet with Rose shows? Ugly facts say not. Rose shows of undoubted excellence have existed at Birmingham, Manchester, Wisbech, &c. Some for years made a struggle for existence—notably Birmingham. Where are they now? Consigned to that limbo, alas! where many others in a moribund condition (he would be a bold man indeed to particularise), must descend, who are now publishing, as I once read in the Journal "WILD SAVAGE" in grim humour stated, only "4d. balance" sheets. As a humble unit of the public, and I confess at once I do not belong to that favoured coterie who write grandiloquently about "the fair denizens of Flora's court," or "the roseate majesty of the queen of flowers" (it is the clerical element which comes out so remarkably strong in this line I cannot help noticing with a smile), but as one who has formed a tolerably strong opinion on the present state of Rose shows in a financial aspect.

I hold that Rose shows with the present large prize lists cannot pay. This is my solution to the first question, and until such exhibitions become popular with the masses, educated as conservative working men to the Dizzy heights of floricultural as well as political refinement, and inhabiting Dr. Richardson's new City of Health, I respectfully submit they ought thus organised never to be expected to pay. It was Wisbech, if my memory be true, which took the sad initiative some six or seven years ago in offering a big prize of £20 to big nurserymen, and which Rose show has since succumbed, like the vernal and too confiding maid in classic lore, under the fatal weight of her own golden bribe. Other provincial Rose shows have been compelled ever since to bid in equally high terms to insure competition, courting eventually sooner or later the same inevitable doom. Analogous examples are not wanting out of the pale of floral enterprise. The provinces also afford a case in point in the West Midland Festival of the

Three Choirs, where from a similar cause—unavoidably large expenses in the management, an annual undertaking, though hallowed by the sacred object of charity, would be in a pecuniary point of view an annual failure, unless by unwritten law a large guarantee fund were handed over to the credit of a debtor exchequer, simply because the leading artistes know their value and ask such exorbitant sums that pecuniary success is well-nigh impossible.

Disagreeable subjects, as a rule, cannot be forgotten too soon, but it is not very long ago that this great clamour for big prizes crippled the career of the Royal Horticultural and Botanical Societies' exhibitions, which, now revised and encouraged with fair reasonable prize lists, far outstrip the former palmy efforts, and are year after year a source of credit to the management, of pleasure to our home and foreign visitors, as well as of well-deserved pride and satisfaction to our leading exhibitors, who can now read in each group of plants they stage the least expensive, widest distributed, and most remunerative advertisement. Why, then, cannot Rose exhibitions be made to pay by adopting this successful precedent?—(1), By Rose nurserymen agreeing to exhibit—because no Rose show is worthy of the name as a school of art both attractive and improving without their exhibits; (2), and exhibit for considerably reduced prizes—because no Rose show in town or country can pay its way unless they consent to do so. I grant that great differences, obstacles, and inequalities exist, and some private sacrifices must be made in the cause; but granting that in the season for Rose shows being so short, distances often so long, and railway trains and service to and from the provinces so tortuous and unaccommodating (to metropolitan Rose shows there never was or will be lack of exhibitors), we find a reason; still I fail to allow these as an excuse for so few nurserymen exhibiting at provincial Rose shows. If Rose nurserymen hold the key of the position, and I as one of the public affirm they do, then they have the game in their own hands—*e.g.*, the whole future of Rose shows, and with them it lies to unlock this well-worn difficulty which has hitherto baffled the efforts, however persevering or judicious, of every energetic honorary secretary, and under the present system of prizes must continue to do so. It is not often that public patriotism and private interests go hand in hand; in this case they do.

The present enormous and yearly increasing sale of Roses mainly owes its origin and continuance to Rose exhibitions. Shall the parent unnaturally be done to death by its own offspring, and that in the Rose nurseries of England? Rather let their fosterfathers take the question in their own hands and answer in the affirmative courteously and successfully, as they know so well how to do, the long-veiled question, Can Rose shows pay? asked by—ONE OF THE PUBLIC.

NOTES ON VEGETABLES.

THE summer just closed (if it deserves the name), has been most remarkable for the dearth of fruit. The kitchen garden crops also have been considerably affected by its peculiarities, and while my memory is fresh I will notice a few of its effects upon the different crops. To begin alphabetically: Artichokes have been abundant and good, the older plantations lasting in bearing to the present time; and this is fortunate, for the spring-planted roots on which we depend for the late-autumn supply have this season done nothing. Asparagus, which promised in February to be very early, was, after all, very late, and the season consequently short; many of the heads also were injured by frost, and altogether it was not up to the usual standard. There was a danger of the crowns not getting ripe this autumn, but the fine September did an immense amount of good for this crop as well as for many others. Some roots placed in the forcing house are starting very freely. French Beans and Scarlet Runners were late, but were good and abundant when they did come. In this respect we were more fortunate than many of our northern friends, some of whom indeed have not been able to gather a dish outside at all.

Spring Broccoli was good, and the autumn crop (Snow's and Veitch's Autumn Protecting), which at one time lagged behind, as did, indeed, all the Brassicas, has commenced turning-in and is very fine. The first-named has been a good old friend, but I think it must give place to Veitch's Autumn Protecting, which turns-in at the same time, or it may be a few days earlier, is larger and of equally good quality. Probably, too, it will prove hardier. Brussels Sprouts, sown in February in a Potato frame, were fit for gathering in September, and

will last till February. We, however, generally make a second sowing in April. The sort with the incurved leaves, generally called the "imported" stock in catalogues, is still the best that I know. Cardoons are late and will not be large; they were badly midewed at one time but have now recovered. Carrots, for which there is always a great demand in the young state, are sown in succession from February till the middle of July. The first lot is sown on a hotbed, and the last, which stands out all winter, on a south border. "French Forcing" is sown for the earliest crop, "Short Horn" for the latest, and it, with "James' Intermediate," for mid-season.

The season has suited Canlidflowers, and they are still good. The last batch of "Autumn Giant" will, however, hardly turn in unless we have a continuance of mild weather, which for the sake of the already fast-swelling fruit buds is not to be wished for. Celery has done well, there has been no fly and no disease. Major Clarke's is still the best, but as it will not stand the winter well we grow "Sulham Prize" for the latest. A row of "Incomparable" or Sandringham White is grown for the earliest crop. The new "Fern-leaved Parsley" is extremely good both for use and ornament; if it proves as hardy as the older sorts, which I do not doubt, it is destined to drive all others out of cultivation. Parsnips were not sown till the middle of April, and all the better for it. We have given up early sowing on our cold soil.

Peas were three weeks late in being ready for gathering (middle of June), but they make up for it now, as we are still gathering (November 8th), almost every day from "Omega," sown the first week in July. This is a most valuable Pea, growing only 2½ feet high, is very healthy, very prolific, and of good quality. Gardeners are much indebted to Mr. Laxton for this and also for his "William I.," which is the best early Pea. These two, with Veitch's Perfection and G. F. Wilson for mid-season, are all the sorts I grow in quantity. Alpha is an early Pea of good quality, but it is not so hardy as William I.

Of Potatoes, the old "Ashleaf" and Myatt's Prolific were good, and were used before the disease had spread much. All the rest were a miserable failure and were not worth digging-up. On the light soils in the neighbourhood they are not so badly diseased as mine were, but they are very small and of indifferent quality. Tomatoes have not done well outdoors as they wanted more warmth, they have also had the disease badly. Turnips with me are excellent; the only sort grown excepting a few early white is Veitch's Red Globe.—WILLIAM TAYLOR.

CHRISTMAS ROSES.

In a mild season the flowers of the Christmas Rose come by or before the festival of Christmas. It certainly is the latest and earliest flower of the year, expanding, as Shakespeare expresses it, when

"The rain and wind beat dark December,"

for this, like a majority of herbaceous and alpine plants, delights in nothing so much as moisture and air. The rain is never too heavy nor the wind too strong for them; but during soft mild winters, though winter flowers appear to advantage, it is better in every way when Nature clothes Flora in snow, provides snug winter quarters for the humblest and gayest of plants. Though hid for a time, Nature gives back in richer fullness the "gold" of the Aconite and "pearl" of the Snow-drop. Winter is only really winter—seasonable and good, when, as Scott has said,

"No mark of vegetable life is seen,
No bird to bird repeats his tuneful call,
Save the dark leaves of some rude evergreen,
Save the lone redbreast on the moss-grown wall."

The fickleness and uncertainty of our climate must be the prompter of our cultivating some hardy plants in pots under glass in order to have them in season with certainty. Plants grown in pots may be more generally useful because portable, but I can picture to myself no sight so fair as a garden under glass of winter and spring-flowering plants. Winter gardens as we usually see them bear out none of the characteristics of a winter garden of northern climes. There are no mossy banks aglow with the Violets, Primroses, and Gentians; Crocuses, Cyclamens, Adonis, sheets of Aconites and Snowdrops, glorious Narcissuses and Hyacinths, Hepaticas, Anemones, Wallflowers, and Stocks are wanting; Arabis and Aubrietias clothe no rock or slope; there is no mountain of winter and spring Heaths, no ravine with its Laurustinuses and Rhododendrons, with other shrubs berried and flowered. Forget-me-nots and Omphalodes are not there; Saxifrages, Tritelcias, Squills, and knolls of

alpine Auricula, with its many congeners, become conspicuous only as absentees; Star of Bethlehem and Christmas Rose are not there, nor are they foreshadowed by autumn Crocuses, Colchicums, the Japan Anemone, and Kaffrarian Iris. These and others come nearer to my ideas of a winter garden than a display of tropical Palms—a desert of grandeur—unvarying similarity, instead of the ever-changing beauty marking the close and advent of the flower season of temperate climes. A winter garden from my point of view would be best represented in winter and early spring by flowering shrubs and plants—an alpinery, in fact, under glass, cold, or only sufficient hot-water piping near the glass to exclude frost. There is a host of plants for furnishing such a house, so that the wonder is they are not more generally employed.

Christmas Roses are fine outdoors, should the weather be open, from December to March. To have this and other gems with certainty in their natural season the plants must be grown under glass. The Christmas Rose is well known, and is deservedly popular, yielding as it does blooms at a time when flowers are scarce; yet it is not so frequently seen as a pot plant as its merits warrant. Large blooms 2 to 3 inches in diameter are freely produced in a light airy house from which frost is excluded; though a little frost does no harm, its exclusion secures the greatest abundance of bloom. Even gentle forcing may be practised successfully, the essentials being light, free ventilation, and liberal treatment.

The plants should be potted at the end of September. Plants with moderate-sized crowns will do well in 10-inch pots; 12 or 13-inch pots will not be too large for large crowns for making a grand new-year display in a conservatory. The size will, of course, need to accord with the size of the crowns. The plants should be lifted carefully; the loose soil coming freely from among the roots should be removed, and it will then be seen the size of pot each requires, allowing about 2 inches space all around the ball for fresh soil. We have only to drain well and work the soil among the roots, in potting pressing rather firm, keeping the crowns slightly raised in the centre of the pot, leaving sufficient space for watering, and plunging the pots to the rims in ashes in a sheltered situation outdoors, watering if dry weather ensue, the weather being usually moist enough in autumn without having to resort to artificial watering. Light turfy loam, with a third of leaf soil or a fourth of well-decayed manure, will grow them perfectly.

Early in December, or in November if the weather be severe, the plants should be taken under glass. The essentials to success are plenty of light, a well-ventilated atmosphere, copious supplies of water and liquid manure (not too strong) once a-week. They do admirably in a greenhouse from which frost is just excluded, yet they will bear gentle forcing, 50° being a maximum from fire heat. Though the plants are best lifted in September, especially when it is proposed to accelerate the flowering by gentle heat, nevertheless they may be lifted from the open ground any time up to December, potted and placed at once in a cool house, with a certainty of a rich reward of blooms in due time.

The plants should be well hardened off in spring and planted out in an open yet sheltered situation in rich light soil, making sure that the ball is thoroughly moist, and watering so as to solidify the soil about it. They will require no further attention, only to remove any weeds that may appear, and in September they may again be taken up, being equally as good as before, or better, inasmuch as they flower earlier the second than the first season, increasing year by year in size and value. Masses or lines of Christmas Roses outdoors are superb. The plants do well in any well-drained soil, but prefer a vegetable one, with shelter and slight shade in summer. I have employed them for winter bedding, lifting them in May and planting in shady borders, removing them to the beds and lines again in November, in which position they like a mulch of leaf soil or cocoa refuse.

Helleborus fetidus is the finest in foliage, which is its only recommendation, making a good centre to a group, having *H. niger* around it, then the purple *H. purpurascens*, banded by Winter Aconite and rings in order of *Hepatica angulosa*, double red, and single white Hepaticas; or *H. niger* major (maximum) for centre, with bands around of *H. atropurpureus*, *H. niger*, Winter Aconite, double blue Hepatica, double red Hepatica, white Hepatica, *Cyclamen hederifolium* for foliage, margined with *C. coum*, alternating with *C. coum vernum*, is a pretty combination.

For pots *H. niger*, *H. niger maximus* (major, giganteum),

H. orientalis, bluish; *H. atro-rubens*, purpled; and *H. olympicus*, white and red, are all suitable.—A.

GROS COLMAN GRAPE.

WITH reference to your note at page 387 of last week's issue, I beg to say that Gros Colman is a somewhat stubborn Grape to deal with, and more especially to colour well, but for the last four years we have had no difficulty in this respect, and to accomplish which we have simply allowed the lateral shoots to extend themselves as much as possible a week or two previous to colouring, and when colouring had commenced never removing a lateral from the Vine. This coupled with a reasonable amount of fire heat I believe to have conducted to perfect finish. Gros Colman is essentially the market grower's Grape, being extraordinarily prolific, of grand appearance, and when fully ripened a long way above second-rate in flavour. We have had it in fine condition up to the end of January, and hope to keep it much longer this season.—W. WILDSMITH, *Heckfield*.

AURICULA NOTES.

I HAVE now been a grower of Auriculas on and off for upwards of forty years, for I began their culture very early, but I have never gone through such an experience as this year. I have grown them on a windy bank overlooking the sea, in the back garden of a town house, and in other places quite favourable to success. My collection at times has only amounted to a few dozen, at others it has filled several frames; but all through those long years, as I look back on them and remember gratefully the pleasure I have derived from them (like all pleasures, bringing their troubles with them), never have the trouble, worry, and loss been so great as this year. I have already recounted my woes, but as the experience I have gained may be of use to others I may be excused if I refer to them again while stating their present condition, for I am not one of those favoured individuals that never have anything go wrong with them. One thing I do happen to know, and that is that others have suffered in some degree like myself, and that therefore there may be more to whom my experience may be a warning.

I began my winter season this time last year with about the best collection of Auriculas I ever possessed both as to quantity and quality; but as the weeks went on I noticed with a great many that set appearance which Mr. Horner speaks of, and of which I did not then know the cause. They made no signs of growth, and yet I could see no mark of drip or over-wetness which one might have naturally expected in such a season as last winter, and it was not until my attention was directed to the remarks about the woolly aphid in the Journal that I suspected what was really the matter. I hurried down to my frames and turned a pot out, and there sure enough was the enemy, or rather the signs of his presence, for I had not yet detected the aphid itself. I hardly knew what to do. The time of year was most dangerous for turning them out and repotting, and as I found by examination that all were not affected I hoped that the pest might not spread; nor do I think it did. Those already affected were apparently past hope: I therefore left them until early in May, when I repotted. This I did very carefully as I imagined, shaking the roots well out and washing them in Gishurst and water as I had been recommended; they were then placed in their summer quarters and I hoped were safe. My horror was great, on examining one or two of the pots in July, to find that the aphid was present in the most abundant and flourishing manner. My determination was soon made, and every one of the plants was turned out and potted again. This time I resorted to no half measures which I had proved to be so ineffective, and separately washed all the roots and the collars of the plants in the creases of which the aphides might find a home, and again placed them in their summer quarters. This was a venturesome proceeding, the question naturally occurring, Would the plants have the power of throwing out a sufficient quantity of roots to nourish the plants after the effort they had made to establish themselves after the first potting? I am now (November 10th) tolerably well satisfied with the result. I do not mean to say either that my collection looks as well as it ought to do or as well as I have seen it in other years, but still, after all it has undergone I am contented.

One thing this misfortune has led me to do, and the only wonder to me now is that I have never done it before, and that is to build a low house for my plants, so that I can get into it

in all weathers and give air without any danger of rain beating in. For a few pounds I managed to convert my old pit into this new one, and look forward, if I am spared, to enjoying my Auriculas as I have never done before. Moreover, those who come to see them will have the opportunity of doing so with greater ease and comfort than when they were on the ordinary stage on which I have heretofore bloomed them.

Another result of this twofold potting is, that I have had no autumn blooming; with the exception of a couple of General Neill and the same of Unique, which are always prone to do this, there have been none. But then the question is, What spring blooming shall I have? and it is of no use to say anything of the effect of this double potting until the bloom next year is over.—D., *Deal*.

THE POTATO CROP.

THIS garden was filled with diseased Potatoes in 1876, and I trenched it and applied ashes mixed with paraffin, and dusted the ground with lime, and used sometimes refuse from the fowl houses and a little stable manure. I planted a peck of Snowflake from Carter's (cut) on March 22nd, and took up 180 lbs. of large Potatoes, 120 lbs. of seed, and 30 lbs. of small on August 6th. There were ten diseased Potatoes among them. They are keeping splendidly, and when cooked they are as balls of flour. I planted Ashleaf Kidney March 12th, and took up a good crop on August 2nd; planted York Regents March 22nd, and took up a fair crop August 8th. Altogether we had 60 lbs. of diseased tubers and about a ton of eating Potatoes and seed.

The disease began in the tops on August 1st, and though the Potatoes were not then ripe we set to work and lifted at once, spreading them out thinly with a sprinkling of coal ashes. They are all keeping excellently, and the quality is first-rate. One of my neighbours who also trenched his garden had hardly any disease. Everyone else suffered terribly in the neighbourhood of Bath.—H. H.

MR. RICHARD SMITH'S NURSERY AT ST. JOHN'S, WORCESTER.

PART II.—THE FRUIT QUARTER AND THE WORCESTER PEARMAIN.

LET the truth be told. I had come to Worcester especially to see the fruit trees, for being an ardent pomologist both as regards the literature and practice of that science I wanted to see the best example of the latter that it was possible for me to set eyes on. When, therefore, Cox said to his master, "Shall we go, sir, to the fruit quarter now?" and the master said, "Yes, by all means," I own I pricked up my ears and hastened my steps.

There are at St. John's 50 acres of fruit trees. "Think of that, Hal! think of that!" Then the climate is very suitable, and as to the soil it seems to be made for growing fruit trees. The wood of the trees is throughout the nursery clean and bright as to bark, the wood of the year of extraordinary length, sometimes 8 feet and more, also thick and hard to the feel, being well ripened. The trees are like healthy well-fed children, who, of course, make the healthiest and strongest men and women. I never saw such an enormous growth for one year, and as was the growth of the Apples so of the Apricots, Peaches, and the rest. I walked round several patches of trees to see if there was any admixture, because if mixed they do not, of course, come "true to name," and then buyers are disappointed; but I could not find a "rogue" or a Judas among them. I can only liken each patch to a regiment of foot soldiers placed in a square. You walk round such a regiment, you see that all the uniforms are the same and the "facings" the same. If a soldier of another regiment were present you would detect his presence at a glance. So of each fruit-tree patch. Say, for example, if they be Lord Suffields, I notice wood, growth, habit, leaf; I should see one of another variety if it were there, but it was not. Three times a-year the trees are carefully inspected, so as to find out any possible mistake, and it is this care, added to the healthiness of the trees from St. John's (and, as said above, if a child is healthy as a child it will be healthy as a man), that is one great reason of Mr. Smith's success and of the vast sale of his trees. As I have given a dozen of the best Roses as seen at St. John's, so I would name a few of the best Apples.

Early Dessert—White Transparent; Early Margaret, pretty on the dish and pleasing to the palate; Irish Peach, A1 among August Apples. Early Kitchen—Worcester Pearmain, kitchen

and dessert, but of this a separate notice presently; Lord Suffield for August and September; then Ecklinville Seedling September and October, and Red Hawthornden somewhat earlier. Medium Dessert Apples—Cox's Orange Pippin and Golden Winter Pearmain. Medium Kitchen—Cellini, October to November; Stirling Castle, on to February; then later for the kitchen the Apple impossible to be too highly praised—viz., Dunselow's Seedling, better, at the fruit shops, known as Wellington; Tower of Glamis, Striped Beefein, and Alfriston complete the number. As to late dessert, Court Pendu Plat, Ribston Pippin, and Sturmer Pippin.

Let me add also a short Pear list for those whose gardens are small:—Summer Doyenné, Williams' Bon Chrétien, Jargonelle, and Bauré Giffard, followed by Bauré Hardy and Louise Bonne; while Bergamotte Esperen and Joséphine de Malines are the best late-ripening Pears. If you want or only have room for one Apricot, there is Large Early for you. As to Plums, Early Prolific and that most profitable of Plums, Victoria. I may notice in passing that at St. John's the trained trees if put in a line would reach eight miles; and as a specimen of the healthiness of the trees in Peaches, Nectarines, and Apricots, as well as Apples and Pears, I have noticed the extraordinary length of the wood made in one year.

Besides the larger fruits, I looked at the stock of Gooseberries and Currants. As a few of the best flavoured of the former I would name Pitmaston Green Gage, Catherine, Rough Red, and Whitesmith. Of Currants there are among the Reds Ruby Castle and Red Grape; and let me call especial attention to Lee's Prolific Black, on which all the berries ripen to the tip, a Currant, too, in which there is no acidity, and it wants little sugar in preserving. There are at St. John's plenty of cordon fruit trees, a form of growing perhaps not yet sufficiently taken up, but on which comes the finest fruit, and which the wind cannot blow off. I looked at the stock of Peaches, Apricots, Plums, Damsons, &c., and saw in all not only a vast supply but also there was not to be seen the least trace of disease.

Among the fruits, though specially noticeable as ornamental trees, I came upon a number of Purple-leaved Filberts, being good bearers of good nuts, and also the leaf as pleasing from its colour as a Copper Beech—eye and palate both pleased.

But next, ay! what next? Well, weary in this work, but not weary of the work, we bend our steps towards the office where luncheon awaits us, for man must eat, although the French wit said to the beggar who pleaded "a man must live," "I don't see the necessity of that in you." Yet each of us does see the full necessity at least in ourselves. Into the office, on to an inner room, the master's own, and what do I see? Some dozens of Worcester Pearmain laid out for me to look at. At once I exclaim, The Doctor was right, the pictures are not exaggerations. Although this has been a terribly unless summer, and no fruits are quite as well coloured as usual, yet what a display of handsome Apples!

To my mind an Apple deserving of the highest place must be up to the mark as regards both beauty and utility. Let me try the Worcester Pearmain by these two tests. First as to beauty, there must be beauty of form as well as colour. The Worcester Pearmain has this to perfection; its form is pleasing to the eye, not squatty, dumpy, or one-sided, or angular and ribbed, but large and broad at the base, and gradually narrowing to the crown—a true Pearmain shape. Any view of it as to shape is agreeable, for it meets the eye pleasantly. Then as to colour, its smooth skin is completely covered with a brilliant red, a glowing glorious colour, a treat to look at in England where we have too little brightness and deepness of colour. Certainly the Worcester Pearmain is among the very handsomest of Apples, and if a table covered with them looked brilliant, what must a tree look like in the glow of an autumn's golden sunlight? As to utility, its size is large, a requisite in a first-class Apple; also it grows well, forming a handsome tree, and crops very freely. I handle Apple after Apple and they seem almost too pretty to eat, but in goes my silver knife and I find the flesh to be tender and juicy and very pleasant. It is a fruit not only to adorn a dining-table, but to be welcome on the plate of the guests as well as to the dish of the host. I brought several specimens home with me; some I roasted, others I baked, and some I boiled, and it was a success however cooked. I pronounce, therefore, upon full examination that the Worcester Pearmain stands the test of beauty and utility, and it must be for ever one of England's first-class Apples, and when further distributed it will be sure to com-

mand a good price in the market, for its appearance is so attractive that it will at once find ready purchasers, who upon buying it will again become its purchasers. What I saw after lunch will supply materials for another and concluding paper.

While sitting and resting out of doors for awhile, Mr. Smith directed my attention to a mansion across the road, over the high walls of which rose to view some fine timber trees. "That," said Mr. Smith, "is Pitmaston House, where in old days lived Williams, a friend of Thomas Andrew Knight, and it gave name to many fruits, such as the Pitmaston Nonpareil Apple, the Pitmaston Orange Nectarine, and several others." Quite a classical residence and very fit to be a near neighbour to St. John's Nursery; and if the ghost of worthy Andrew Knight should ever walk and take a look at the gardens of Pitmaston, I am sure he will walk across the road and much gratify his ghostly, and of course fruit-loving nature, by a look at and a walk through its fifty acres of fruit trees. I walked there in the body, and was charmed when there, and treasure-up the sight as one delightful for ever to my pomological instincts and memory.—WILTSHIRE RECTOR.

ERRATUM.—In part I., p. 369, column second, line twenty-one, there is a clerical error, I mean a printer's error, for I don't own to it. For "a queen-amidst look," read a "Queen-Annish look," so many of the houses belong either to the Queen Anne era, or show symptoms of the style of her reign.—W.R.

SPECULATIONS AS TO THE NATURE AND ORIGIN OF THE POTATO DISEASE.—No. 2.

I WILL now refer to the theory of electricity. The disease has been supposed to have been caused by some peculiar electrical state of the atmosphere. The great objection to this theory is the same as the others—that it will not account for the disease appearing only in 1845, unless it could be shown that some peculiar condition prevailed not before known, which is very improbable. I think that there is no doubt the disease spreads rapidly in damp thundery weather, but that is a different thing from the electrical state of the atmosphere being the origin of it. Some years ago there was a discussion in a contemporary with regard to the connection between the Potato disease and electricity, and a writer calling himself a "LOVER OF NATURE" made the following remarks, which I cannot do better than produce here:—"The theory advanced that the Potato disease is caused by the action of electricity on wet tubers appears to me wholly untenable. That the disease should appear three days after a thunderstorm is no proof that lightning produced it, for it might be a mere coincidence, or it might arise from other attendant circumstances. Your correspondent makes no attempt to support his theory by known facts in the science of electricity; nay, its supporters (for it has many) seem to look upon electricity as another Ariel playing all sorts of odd pranks and setting all laws at defiance. Now this is not the case. All electrical phenomena, including thunderstorms, are subject to certain fixed laws which never vary. For the benefit of your non-scientific readers I will trespass a little on your space to explain the phenomena which take place during such storms. All thunderstorms are produced by one of the following causes:—Either first, by the passage of the electrical fluid from one cloud to another; or second, from the earth to the clouds; or third, from the clouds to the earth. This takes place, however, only under the following circumstances:—The cloud or part of the earth from which it passes must be in a positive state of electricity, and the cloud or part of the earth to which it does pass in a negative state of electricity; the exchange goes on until both are reduced to the same condition. Another important law of electricity is that it moves by conduction—i.e., as some substance, such as metals, water, &c., are conductors it will pass along them; but glass, fur, atmospheric air, &c., being non-conductors almost totally obstruct its passage. As the two first causes of thunderstorms enumerated above cannot influence vegetation we will pass over them and come to the third—the passage of the electric fluid from the clouds to the earth, which takes place in the following manner:—A cloud highly charged with positive electricity being surrounded by air, which is a bad conductor, cannot discharge its excess of electricity till it is in the vicinity of some good conductor, such as a church, a house, a tree, or any other high object, to which it immediately passes (generally in a zig-zag direction, owing to the resistance of the air) and is conducted to the earth, where it is distributed in a thousand different directions. Now, with these few simple though well-established laws before us, what are we to make of the electric theory? The only data advanced in support of it are

—first, it has frequently been observed that the Potato disease made its appearance three days after a thunderstorm if the weather continued wet or damp, but if the weather was fine very little disease appeared. If this is a fact that can be borne out by general observation, it would lead me to suppose that excessive wet after dry hot weather had produced disease and not electricity. Second, the illustration which is quoted in support of the theory is worthy of notice. That the disease attacked a plot of Potatoes in a diagonal direction is to me no illustration whatever, for it appears to be at variance with all the known laws of electrical phenomena. The electrical current could not have been confined within the space described unless there was a more highly conducting medium running in that direction, which is improbable; and if so, under such circumstances it could not have injured the Potatoes." With these remarks I am inclined to agree, and think that electricity has little or nothing to do with the origin of the disease; however that may be, it is certain that the disease is worse in Gloucestershire than it has been for many years, and that there has been a remarkable absence of thunderstorms.

I will then for the present abandon the idea of electricity as having anything to do with the origin of the disease, and will endeavour to start another theory, which if proved would satisfy all the conditions required, and explain where the disease originated, how it came here, and why it did not show itself before the year 1845. But in order properly to support my theory it is necessary for me to give what some of your readers may think rather a too lengthy description of several of the new plants, insects, and diseases which have lately appeared in this country, the origin of some of which is known; for it is only by practically investigating all the known facts relating to the new insects and other diseases that have of late years been introduced into this country, most of which seem to point to a common origin, that we can hope to advance our knowledge of the subject.

Some years ago a strange weed appeared in our brooks and rivers—the *Anacharis canadensis*. It flourished and spread amazingly and became a regular nuisance, almost filling up the watercourses, and has continued so down to the present time. I have seen various ways mentioned to account for its introduction to this country. One report said that a *savant* grew it in a pond in his garden for experimental purposes, and it spread from thence to the neighbouring streams. But however it got here, there is no doubt whatever as to its origin. The plant is well known. Now, if this had only been a fungus or other small plant-growth not well known or observed, how very difficult it would have been for us to account for its presence and sudden appearance with us.

Again: About the year 1845 a disease very mysteriously appeared which attacked the Vines. It was a species of fungus called the *Oidium Tuckeri*. It was very prevalent in this country, and spread over a great part of the Continent. Mr. Don, a Portuguese merchant, wrote a pamphlet on the Vine fungus, with suggestions as to the remedy. After speaking of the devastating nature of the disease he goes on to say, "There are several circumstances which lead to the proximate cause of this so-called disease, is to be found in some abnormal condition of the atmosphere, in conjunction with a diminished power of resistance from other causes in the Vine itself." He then proceeds to show that the disease was derived from the atmosphere, because he managed to preserve his own Grapes by brushing the fungus off with a camel's-hair pencil; but this, of course, only showed that it passed through the atmosphere, not that it was caused by it. He then attributes the commencement of the disease in Portugal to the fact that the soil was not properly cultivated in the three or four years ending in 1852, and that there was not sufficient rain to cause the young stems to decay, which, by the way, were the only manurial dressing the Vines had. He then further says, "In 1851 the rain came down in October and lasted with little intermission until May, 1852, of which year the spring was cold, wet, and late. In May vegetation became rank and luxuriant; the Vines produced branches of twice or thrice their usual length, and formed leaves of enormous size, and these Vines were not sufficiently pruned, and so the Vine was well prepared in the following year to become an easy prey to the *Oidium Tuckeri*, which, unlike other fungi except mildew, which it resembles, is not so ceremonious as to wait until its victim is dead and decaying before making its attack, but appears on the contrary to fasten on its living juices with a pertinacity so great that the weakened resistance of the Vines generally has not been able to shake it off. In

cold and damp localities, where vegetation was most rank, it appears to have revelled in excess."

On reading the above one would almost think he was writing on the subject of the Potato disease, and the *Peronospora infestans* particularly, as he refers to the electrical state of the atmosphere; but it is not of thunderstorms and the highly electrical state of the atmosphere that he complains, but of the entire absence of them. This pamphlet was, no doubt, highly interesting and instructive at the time, but the writer fell into several errors. The disease did not originate in Portugal as he thought. It was known in France several years before it appeared there. According to Mr. Berkeley, a good authority, this Vine disease first appeared in East Kent in 1845, and was in 1847 recognised as a parasitic fungus to which the name of *Oidium Tuckeri* was given, after the cultivator who first studied its growth. The origin of this disease as far as I know has never been satisfactorily made out, but I suspect its American origin, for although the disease was carried to the United States with exported Vines, all the varieties of the *Vitis Labrusca*, from which all the better quality of the American Vines have sprung, whether in their own or foreign countries, were remarkably exempt. However that may be, it is a consolation to us to know that a remedy was found, and that if the leaves of the Vine were well damped and then powdered over with sulphur the *Oidium Tuckeri* was subdued or kept within reasonable bounds.—AMATEUR, Cirencester.

FORCING ASPARAGUS—ARTIFICIAL MANURES.

ALTHOUGH artificial manures may be applied with great advantage to Asparagus when growing naturally in the beds I do not think they are much benefit to it in forcing. We cut a good dish of Asparagus on the 17th inst. from a dungbed under glass. After the roots were put in and covered with soil a quantity of nitrate of soda was spread over one end of the bed. The same quantity of salts of potash was sprinkled over the other end, and the centre part was left without any artificial dressing. The produce of this part is just as plentiful and strong as either of the ends. If it is not an unchemical way of expressing it, I think the Asparagus grows in too short a time when forced for the manure to be utilised to any great extent, and therefore it is unnecessary to apply it.—J. MUIR, Margam.

THE DARLEY DALE NURSERIES.

THIS year the Fates sent me to Derbyshire, and my wanderings took me to Darley Dale, famous for its magnificent churchyard Yews—probably the finest in England—and so it came about that I found myself a visitor to the Darley Dale Nurseries. I went to Darley Dale expecting to find a small country nursery; for was I not far away from the centres of trade? I had for some days previous been a sojourner among the pleasant dales of Derbyshire, and had often spent hours without seeing a single fellow creature; so somehow I fancied as I neared my destination I should find a small place where possibly I might see some few things more or less cultivated, and also, perhaps, nothing worth recording. I gained admission to the nursery, not through the main entrance, but through one of those quaint narrow openings between two upright stones oddly enough called "stiles" in Stonyshire, and soon found myself among evidences that there was more to be seen at Darley Dale than I had counted on. There were all about me signs of great activity. I saw the squat propagating frames, so familiar in our nursery grounds, in large numbers and in every direction. I braced up my expectations to a higher pitch as I gradually neared the house and offices. It was not long before I made my way to Mr. Smith's house, a well-fashioned old stone edifice, the walls of which are plentifully adorned with suitable vegetation. The preliminaries over, I was introduced to Mr. Herbert Smith, who courteously undertook to be my guide, and without loss of time we set off on an expedition of sight-seeing. My companion informed me that he would first take me to one of their nurseries called "Siberia" some two miles away, and situated on some table land 1000 feet above sea level, to reach which we had to walk along, or rather climb up, the road leading from Newhaven through Darley to Chesterfield. But though the road was steep the surroundings were most charming, and were rendered doubly so by the rich autumnal tints which prevailed everywhere.

I learnt that the Darley Dale Nurseries consist of some 140 acres, lying about in various portions of the dale and

neighbouring heights, and that some 26 additional acres are about to be added. "Siberia" was at length reached, and there I found on a most exposed spot 30 acres of excellent peat land, and covered with Rhododendrons, Heaths, Menziesias, Andromedas, Ledums, Azaleas, Kalmias, and Conifers—all in robust health, for puny plants would never stand wintering in such an exposed and elevated situation. From this nursery we went to another and another—in all nine or ten, each being the home of plants happy and thriving in the appropriate variety of soil, climate, and local circumstances.

What struck me most at Siberia after the immense breadths of Rhododendrons was the enormous quantity of hardy Heaths. I do not exaggerate when I say there are many acres of them. Nor let it be supposed that there are only some half-dozen sorts; there are at least fifty, many being most distinct and ornamental. Thus, of *Erica tetralix* there are ten kinds—the cross-leaved white, the woolly-leaved, Mackay's crimson, the Cornish, the ordinary white form, the large-flowered, and the red. But *Erica vulgaris* outnumbers this kind considerably, there being twenty sorts grown, of which Hammond's white, the rigid, Allport's (crimson), the golden-leaved, and Foxii, a very pigmy among Heaths, most interested me. There, too, in vast quantities is *Erica carnea*, and a white form shortly to be distributed, and which seems to be as useful and ornamental as the well-known flesh-coloured variety. From what I saw I am convinced that hardy Heaths are not known half as much as they deserve to be.

The Rhododendrons, from tiny seedlings scarcely visible up to grand well-grown specimens, including a magnificent assortment of the best named varieties, were something to remember, and I was informed the stock of these plants numbered over five millions! also that of hardy Azaleas there were 200,000, and of Heaths 150,000. These numbers are not guesses, but are actual figures from the stock books of the business. A very curious and interesting piece of information is afforded by the same books as to the popularity or demand for certain plants. Thus, I found there was a stock of 10,000 *Picea nobilis*, while of the handsome, varied, cheap, and useful *Cupressus Lawsoniana* the numbers run up to 50,000. Of Laurels there are 100,000, of Box trees 20,000, of Limes 10,000, and of Mountain Ashes 200,000. These statistics might be indefinitely added to, but enough has been given to illustrate the varying demand and the vigorous efforts made to meet it in what to me is the sweetest of the Derbyshire dales.

I saw some very pretty forms of *Cotoneasters*. *Simmondsii* is, of course, in abundance, but *C. rupestris* is to my thinking vastly superior; while one variety, the name of which I forget, seems an admirable substitute for the richly-berried *Pyraeantha*.

Of berried plants, of which most of us are fond, why are not *Pernettyas* more generally grown? At Darley Dale I saw plants rosy pink in hue from the masses of fruit borne by them. They are dwarf, evergreen, profusely covered with berries, and handsome in the extreme when in flower. A plant which I always thought to be *P. mucronata* Mr. Smith told me was *P. speciosa*. Then, again, for those who desire a most useful berried plant for cover, what is there better than *Gaultheria Shallon*? It is most fruitful, very cheap, and handsome withal.

I find I have exhausted my space and left no room to dilate on many other subjects of interest. I should like to tell of the glorious collection of hardy Ferns, which is a pet speciality of Mr. Smith, and could fill a column with brief references to noteworthy Conifers which I saw in prime condition. I could also explain a phenomenon of the cottage gardens of the district, in which I saw superior vegetables, handsome shrubs, and pretty flowers. I may, perhaps, on a future occasion, if the Editors will allow me, have something more to say about what I saw in and about Darley Dale.—
PHILANTHES.

[By all means say more.—EDS.]

SCOTTISH HORTICULTURAL ASSOCIATION.

THE ordinary monthly meeting of this Association was held in 5, St. Andrew Square, on Tuesday evening, the 6th of November. There were about ninety members present. The President occupied the chair. After the reading of the minutes fifteen new members were duly elected, which makes the membership now over two hundred.

Mr. Robertson Munro, Abercorn Nursery, Edinburgh, read an able and interesting paper on "Hybridisation," being a continuation of a former paper on the same subject. He gave details of his own experience in hybridising and cross-breeding,

and also referred in general terms to Mr. Darwin's views on the subject. An animated discussion followed on the opinions advanced by the essayist. In illustration of his paper Mr. Munro exhibited specimens of various hybrids, especially *Passifloras*, the result of his own manipulation. The thanks of the meeting were awarded to him for his paper.

The Chairman announced that Mr. John Downie, of Messrs. Downie & Laird, had placed at the disposal of the Association the sum of £5 to be divided into four prizes for competition by journeymen gardeners, members of the Association, for the best original plan of a flower garden. The meeting awarded a hearty vote of thanks to Mr. Downie for his handsome donation, and remitted the matter to the Council, who have arranged that all plans be sent to the Secretary, under motto, by the 1st of February, 1878, each accompanied by a sealed envelope containing the competitor's name and address.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

DRACENA REFLEXA. *Nat. ord.*, Liliaceæ. *Linn.*, Hexandria Monogynia.—"This is the typical form of the Bois de Chandelle of Mauritius. The plant is spread widely through tropical Africa and runs into numerous varieties. It has long been known in cultivation. It may be known from the other cultivated *Dracenas* with lanceolate sessile leaves by the looser disposition of its leaves upon the stem and by its solitary flowers, with a very short perianth tube. *D. cernua* of Jacquin is a variety of the same plant, with a drooping panicle, longer pedicels, and leaves edged with red. Our specimen flowered some time ago in the Palm house at Kew. It is an erect shrub, with slender branches, reaching a height of from 6 to 20 feet."—(*Bot. Mag.*, t. 6327.)

VANDA CÆRULESCENS var. *BOXALLII*. *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—"This lovely form of *Vanda cærulescens* was figured from a specimen flowered by Messrs. Low of Clapton last June. It is merely a horticultural form of the type species, presenting no tangible botanical difference entitling it to rank as a variety. Those specimens in which the outer perianth becomes pure white must be especially charming. In the flowers figured they are a very pale violet."—(*Ibid.*, t. 6328.)

ECHEMEA (*CHEVALLIERIA*) *VEITCHII*. *Nat. ord.*, Bromeliaceæ. *Linn.*, Hexandria Monogynia.—"This is a very fine new Bromeliad, discovered by Gustave Wallis in New Grenada in 1874, and introduced this present year into cultivation by Messrs. Veitch. It is closely allied to the Costa-rican *Echeema Mariae* reginæ of Wendland, and belongs to the section *Chevalliera*, which was proposed as a genus by Gaudichaud (*Atlas, Voy. de la Bonite*, tab. 61-62), and has been maintained as such by Grisebach and Morren."—(*Ibid.*, t. 6329.)

CALCEOLARIA LOBATA. *Nat. ord.*, Scrophulariaceæ. *Linn.*, Diandria Monogynia.—"We are indebted to Messrs. Veitch for this very interesting addition to our cultivated species of *Calceolaria*. It is a dense-growing herb from 7 or 8 inches to a foot or more in height, flowering profusely in the autumn. The corolla is pale yellow with deep brown-purple spots towards the base of the lower lip, which is remarkably long and folded back upon itself about the middle."—(*Ibid.*, t. 6330.)

BOLLEA LALINDEI. *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—"For the discovery of this beautiful species we are indebted to Mr. Lalinde of Medellin. A fresh flower was furnished to Dr. Reichenbach by Messrs. Veitch in 1874. Our figure is from a specimen flowered by Messrs. Williams of Holloway last August, which differs materially in colour from the plant described by Reichenbach. In the latter the flower is of a beautiful bright violet with the tip of the upper sepal green, the lower half of the lower sepals brownish purple; the lip deep orange and the column deep purplish. Notwithstanding these great differences in colouration, there is no doubt as to the agreement of the specimen here figured with Reichenbach's specific description in the diagnostic characters taken from the peculiar form of the lip, and the great breadth of the column which completely arches over the plaited palate."—(*Ibid.*, t. 6331.)

ROSES IN NOVEMBER.

IT is many years since we have had such a fine autumn as we have had this year. Roses were beautiful here until November 7th, when I cut a bouquet of flowers which were equal to summer blooms, the following being the finest:—Dupuy-Jamain, Victor Verdier, Duke of Edinburgh, Baronne de Rothschild, Charles Lefebvre, Niphotos, and last—that best of

all—old Gloire de Dijon, which seems just now to be all in its glory, being covered with both buds and flowers. But, ere this is posted, the wind and rain have brought the reign of the Roses to an end.—T. J. HARRISON, *Roselee Gardens, Chester.*

SCHMIDT'S BIGARREAU CHERRY.

FIVE years ago I obtained from Sawbridgeworth a collection of Cherries, and one of the finest of them is the variety above named. The tree has proved a free bearer, and the fruit is extremely fine. I can recommend this Cherry to those who have it not and who are contemplating adding to their collections, and I apprehend that I cannot do so at a better time than on the eve of the planting season. It makes a noble dish for the dessert table, and is valuable for exhibition purposes. The fruit is of a large size, round, and somewhat oblate. The skin is of a deep black colour, and there is a large style mark

the Escallonias, especially for walls or covering steep banks. The best of these is *E. macrantha* with its glossy shining leaves and pink flowers. *E. rubra* is also very pretty, but not equal to the foregoing. *Garrya elliptica* is also suitable for planting in similar situations, and when covered with its graceful drooping catkins is very pretty.

Hollies, both green and variegated, succeed very well. *Laurustinus*, an old favourite, is also suitable. Myrtles I have seen growing and flowering well only 200 yards from the sea; and is it not a treat to see these beautiful shrubs growing and flowering in the open ground? Sweet Bay also succeeds well, and so does the Oval-leaved Privet. Another shrub that grows very fast is the Tamarisk; planted on the outside of some shrubberies next the sea its growth was remarkable. *Aucuba japonica* and the new male varieties succeed, also the *Arbutus*.

Among deciduous shrubs foremost stands the *Hydrangea*, which along the coast produces large umbels of beautiful blue

Fig. 78.—SCHMIDT'S BIGARREAU CHERRY.

on the apex. The stalk is stout, 2 inches long, and rather deeply inserted; flesh dark, tender, and very juicy, with a fine flavour. The stone is very small for the size of the fruit.—A. N. G.

We are able to submit an illustration of this fine Cherry, which was received from the Société Van Mons by Mr. Rivers. It is the largest of all the Bigarreau Cherries.

SEASIDE SHRUBS.

AMONG the few shrubs that will stand the seaside winds with impunity and flourish luxuriantly along the west coast of Wales the *Euonymus* takes high rank. Not only do they grow rapidly in the full face of the furious westerly gales, but become large bushes in very exposed situations, which they refuse to do more inland except in very sheltered places. The best sorts that I have found succeed along this coast are *Euonymus japonicus argenteus*, *E. japonicus aureus*, and *E. japonicus radicans*; the latter, being of dwarf growth, is suitable for planting near the margin of shrubberies.

Other things that do capitally well along this west coast are

flowers; also *Buddlea globosa*, Elders of sorts, *Deutzia scabra*, Guelder Rose, Fuchsias of sorts—such Fuchsias! 7 to 10 feet high and as much through—and *Leycesteria formosa*.

I will next send an account of the forest trees that succeed best on this coast. My excuse for sending you these notes is the bareness in beautiful shrubs of many gardens along the seacoast, which I think is more owing to not knowing what to plant than from want of will on the part of owners of gardens.

—GEORGE COOKE, *Nannan Park Gardens, North Wales.*

NOTES FROM CORNISH GARDENS.

MOUNT EDGCUMBE,

THE SEAT OF THE EARL OF MOUNT EDGCUMBE.

"THE most striking feature in a general view of Plymouth Sound is the park of Mount Edgcumbe, the seat of the noble family of that name, which, comprising the lofty hills on the western slope, presents a varied expanse of foliage broken by tall red-stemmed Pine trees descending to the water's edge." Thus saith Murray: and as I had my first sight of those lofty hills of such commanding aspect, and withal so picturesque, it

seemed quite in the ordinary course of things to go to them from Pentillie, as I was about to do.

Pleasant was the drive "o'er hill and dale" to the steam-boat pier at Saltash through a well-wooded country, and yet so broken that choice bits of scenery kept coming into view; and near Saltash the estuary of the Tamar, the Hamoaze and the distant Sound, all brightness and life, opened out before us. No time was there, however, to linger; on past the quaint old houses of Saltash, all jumbled together in the oddest manner imaginable, down to the pier in the very nick of time. "On board with you, cast off, go on ahead!" all in a breath, and away steamed the boat past the mighty viaduct rising 170 feet above the water, and nearly half a mile in length, down the Hamoaze, among grim war ships—ancient "liners" and modern ironclads; a training ship with its swarming population of nine hundred boys, the huge "Enchantress" at torpedo practice, the equally huge guardships apparently

equally teeming with life. Yonder is a cupola ship sneaking away up Millbrook Creek as if ashamed to show its ugly form. That red-painted vessel moored close in shore away from all other ships is a powder tender; no lights allowed on board. What a dismal existence for those in charge of her at this season of the year with thirteen or fourteen hours of darkness! Sweet be their sleep! On past the arsenal, with its huge piles of shot and shell, to the pier at Devonport. On land once more, but not to stay. "Boat ahoy for Mount Edgecumbe!" and we are off again amongst dozens of other boats shooting through the water in every direction past more ships, and in a few minutes are at our destination.

Close by the pier are the park gates. We enter, and as we proceed to the garden entrance the house is visible at the end of a wide avenue (fig. 79), which from the proximity of numerous other trees has a good deal of the effect of a glade. Wherever trees stand out singly here they are frequently ex-

fig. 79.—MOUNT EDGECUMBE.

posed to the fury of severe gales, to which some of the trees in this avenue have succumbed, and have been replaced by young ones that were evidently not thriving. No process in gardening can be more unsatisfactory than this patching an old avenue; it never answers, the young trees after the first season being usually in a state of semi-starvation, for the greedy roots of the old trees rush into the newly-stirred soil and rob it of all nutriment. It is better, therefore, to accept the decay of the old trees as a stern and undeniable fact, doing all that is possible to protect them from the baneful effects of storms by planting sheltering belts and clumps on the windward side.

The pleasure grounds run down to the water's edge, and the entrance leads straight into an Italian garden in exquisite keeping with numerous walks, all converging to a central fountain, each walk having an avenue of magnificent Orange trees in tubs. The average height of these wonderful trees must be quite 15 feet, and their heads are of a proportionate diameter. The bright green hue of the glistening foliage betokened perfect health, as did also the hundreds of fruit with which every tree was heavily laden. The orangery in which the trees are wintered is a fine building overlooking the garden and forming one of its boundaries—a semicircular belt of shrubs sweeping around the other sides. The appearance of this garden is novel, striking, and very pleasant, the extraordinary size and healthy condition of the Orange trees altogether robbing it of that air

of formality which is usually so offensive in less successful attempts at imitations of the Italian style of gardening.

From the Italian garden a walk takes us to two other enclosures, termed the French and English gardens. While avoiding tedious details I may note certain objects of interest which they contain. Several excellent examples of *Chamærops Fortunei* are planted out in permanent positions, and are evidently thriving. A *Catalpa* in full bloom was very attractive, not only for its blossom but also for its large size, the stem, measuring about 8 feet in circumference, bearing a very large spreading head. Here too was a grand old Cedar of Lebanon; a Holly upwards of 50 feet high laden with berries, and quite worthy of its position; a healthy *Salisburia adiantifolia* about 20 feet high; *Osmanthus ilicifolium argenteum variegatum*, 7 feet high, quite the finest silvery *Osmanthus* I have seen; several magnificent old Cork trees; fine examples of *Rhododendron arboreum*, the scarlet tree species from Nepal and others; a huge Bamboo, which had flowered and died like so many others which I saw in different parts of Cornwall. All of them were dead, but I hope the deplorable fact will not hinder others from being planted, for we have no substitute—nothing like it in form, size, or beauty. This is the Himalayan species *Bambusa falcata*, exceeding in size all the Chinese and Japanese species that have been tried in this country. The situation was evidently a favourable one, for the

slender tapering stems of the Bamboo were 20 feet in height—some standing almost erect, others bending gracefully outwards, all having numerous branchlets pendant with heavy panicles of seed. Other fine trees and shrubs might be enumerated, for the gardens are rich in them, and they impart tone and character nothing else can do, and I may be pardoned for not dwelling upon such trivial matters as flower beds and bedding plants—all very good in their way. Rather would I seek to point a lesson here by showing that while there can be only one Mount Edgumbe, yet in every garden more may be done to establish permanently such objects of perennial-growing beauty as abound here—not a crowd, but a few well chosen, well placed, and in keeping with the position and extent of the garden.

I hope next to take the reader through the more picturesque parts of the gardens and woods, and to explain certain other useful lessons worthy of general application.—EDWARD LUCKHURST.

(To be continued.)

CHRYSANTHEMUMS AT SLOUGH.

DURING the last few years some examples of this beautiful flower have found their way from the Royal Nurseries to the exhibitions at South Kensington. This year no good opportunity has been afforded to exhibit Chrysanthemums, and Mr. Turner wisely decided to make an exhibition at his own nursery. As a general rule the flowers are late this season, and some of the exhibitions have had to be postponed. Now, however, the flowers at Slough are at their best, yet the exhibition will be continued for some considerable time, as the plan adopted here is different from that we used to see either at Mr. Salter's nursery, Hammersmith, or at Stoke Newington by Mr. Forsyth. At both those places the whole, or nearly the whole, collection was in flower at one time, except in so far as some sorts were naturally earlier than others, and, as a rule, but very few varieties were in flower at Christmas, and those not of the sorts most valuable for cutting.

The accommodation at Slough for such plants is very much greater than that of the celebrated growers mentioned above, and not the least valuable is a long house facing north, where the plants are yet in bud and promise to make a grand display after those in flower have been removed from the show house. This is a span-roofed structure 100 feet long and 14 feet wide, entirely filled with plants in flower. The arrangement is exceedingly effective. The plants are in such a position that the flowers are just under the eyes of the visitors, so that they can be examined without any inconvenience—a great advantage this, as we have seen the stems grown so tall that it was necessary to mount a short ladder to minutely examine the flowers.

Mr. Turner grows his plants in 6, 7, and 8-inch pots, and they are not grown too strongly, but strong enough to produce abundance of useful flowers either for decorative purposes, to cut for bouquets, or to place in glasses to decorate rooms. His object has evidently been to make an effective exhibition, and he has succeeded. The largest proportion of the plants have been grown on the natural system without any attempt at artificial training. And after all the most natural way is the best; it is more pleasing and better appreciated by the general public than is formal training. Better half a dozen good flowers than half a hundred flowered out of character either from bad training or unskilful culture.

All the new varieties are here, but—and we are sorry there should be a "but" in the case—evidently the mantle of Mr. John Salter has fallen on no one. What a treat it was to go to Hammersmith and see the new varieties intended to be sent out the following season, especially after the Japanese came in, when there used to be about a dozen distinct varieties annually. Anything new amongst the large-flowered Chinese sorts now seem merely to be sports of a different colour from well-known sorts. Mrs. George Rundle, for instance, is grown here by the hundred, and because it is grown everywhere so extensively we are the more likely to obtain sports from it. The first sport, a pale yellow or sulphur flower, was named George Glenny, and from this was obtained a variety of a deep yellow colour, which was named Mrs. Dixon. These three sorts are well grown here. There is a primrose-coloured sport from Empress of India, which will be very popular, as it is a good sport from the largest and purest white in existence. The best white flowers beside the above are White Globe, Isabella Bott, Eve, White Venus, and a very late-flowering variety named Mrs. Wood. The best amongst yellow sorts are Jardin des

Plantes, a superb flower, raised probably thirty years ago, but not yet equalled; we would place Golden Beverley next to it. Golden Dr. Breck is also a fine golden yellow, and when well grown Iona may be placed in the highest position. Aurea multiflora, though not large, is the neatest flower in cultivation. Annie Salter is what is termed a reflexed flower, but it is clear yellow and makes a handsome specimen plant. There are some grand flowers of the various shades of pink and rose colours. One of the best is Princess of Teck, a noble flower, bluish tinged with rose, the petals broad and beautifully incurved. It is one of the more recent of Mr. Salter's flowers, but was sent out a year or two ago under another name. Pink Perfection, syn. Miss Mary Morgan, ought to be in every collection. Lady Hardinge, Her Majesty, Hero of Stoke Newington, Princess Beatrice, Princess of Wales, Lady Slade, and Venus are the cream of these colours.

More good flowers than we already possess are wanted in the purple and rose-crimson shades of colour. The best at present in cultivation are Prince Alfred, a noble flower, but the outer petals soon decay; Prince of Wales, and Dr. Sharpe. The last has beautifully reflexed flowers and makes a handsome specimen. Amongst Indian reds or chestnut reds there are John Salter (this sort ought to be placed near the glass, else the flowers come loose, when well done it is the best in this colour); Mr. Gladstone, dark red, the reverse of the petals looking as if they were polished; Golden Eagle, General Bainbridge, General Slade, Sam Weller, St. Patrick, and Antonelli (the last named, though a perfectly formed flower, is not large enough unless very well grown); Comte de Morny is a useful decorative flower we had not seen before; Caractacus is white tinged with pink; Triomphe de Nord a dull crimson-coloured flower.

In the Japanese class there are a few good new flowers, notably a golden yellow, earlier to bloom than Grandiflorum and equal to it, named Fulton. To Kio is a brilliant crimson scarlet flower, the reverse of the petals orange. The best of the older Japanese sorts are Bronze Dragon, Duchess of Edinburgh, a peculiar rosy lilac-coloured flower, a hybrid from the Anemone section; Elaine, Fair Maid of Guernsey, James Salter, very early; Purpureum album, Red Dragon, The Cosack, and The Sultan.

The small Chusan Daisy or Pompons are very pretty and useful for cut flowers. Amongst the best and most distinct are Bob, Cedo Nulli, and the golden and lilac varieties of it; Dick Turpin, General Canrobert, Marabout, Mdle. Marthe, a very fine pure white-flowered variety; Mr. Astie, Mustapha, St. Michael, St. Thais, and Salamon. All the above, besides having the best flowers, are best adapted for forming specimens.

An interesting feature in Mr. Turner's collection is about 150 standards of the large-flowered and Pompon varieties. The stems are about a yard high; each head, which is semi-globular in form, is composed of three or four varieties, distinct in colour. They were grafted on after the stem had attained the desired height. The operation is easily performed; hardly one of the grafts missed taking, and they were merely tied on with a strip of matting, the plants at the time being in a greenhouse kept rather close. Exhibitors might take a note of this, and try to graft a difficult sort on a free-growing standard.

In looking through the other houses there is something to interest every class of gardener. The immense stock of Carnations and Picotees is rapidly being dispersed over the country, and the plants seem to be thoroughly well rooted. Auriculas are in great demand; indeed, the supply is quite inadequate to meet it—a sure sign of the increasing taste for this old favourite. Pinks a year or two ago were getting into a weak state, and growers could scarcely obtain plants; now the supply seems equal to the demand for them.

Looking through the greenhouses we noted a few plants that would be useful for supplying cut flowers. There were several hundred 5 and 6-inch pots of a very pretty Scrophulariaceous plant with pale blue flowers named Browallia elata. It is a Peruvian species, but succeeds well in a greenhouse temperature. In juxtaposition to it were many small pots containing nicely-grown plants of Salvia splendens. Its beautiful bright scarlet flowers were very effective. Amongst Bouvardias the most useful seems to be B. Hogarth and the white or bluish sport from it, B. Vreelandii.

Tree Carnations are in thousands, and although they are looked upon with disdain by the genuine florist they are justly esteemed by the general public. We noted Osman Pasha as the best in its class. It fairly beats Proserpine and La Grenade. Its rich crimson scarlet flowers are superbly finished.

There is also a very free-flowering scarlet variety which will speedily make a mark for market purposes when it can be obtained in quantity. Dwarf plants in 6-inch pots were producing about two dozen of flowers. It seems to be of French extraction, and is named *A. Alegatiere*. Sir Garnet Wolseley is a distinct flower, and very pretty indeed.

There was just time to look at the specimen Roses in pots. There is the gigantic specimen of Paul Perras, the conqueror in many well-contested fields. Next to it a marvellous example of *Céline Forestier* and all the other specimens that brought their owner so much renown last summer. To prevent injury from furious tempests they are moored with strong twine from every point of the compass to a framework of wood. Good order prevails in every department of these celebrated nurseries.—VISITOR.

CHRYSANTHEMUM SHOWS.

NOWHERE are Chrysanthemums grown better than in the metropolitan district, and the exhibitions of them bear testimony to the skill of the cultivators and to the superlative value of this flower for autumn decoration. Chrysanthemum shows not only stimulate to superior cultivation in their several districts, but encourage the higher culture of the flower generally; for a record, however brief, of success affords an incentive for other growers, and British gardeners, as a rule, do not like being behind their neighbours. The shows also afford opportunities for comparing the merits of different varieties, and it may be taken as a tolerably sure guide those varieties which are mentioned the most frequently are the best not for exhibition only, but for home decorative purposes. The dates of several shows were fully too early for this late Chrysanthemum season, for we have noticed many plants with unexpanded flowers, and others which give evidence of having been "forced," and on this account some exhibitions have not been so good as in previous years.

BRIXTON, STREATHAM, AND CLAPHAM.

The autumn Exhibition of this Society was held on the 14th and 15th inst. Although not quite up to the average some very good specimen plants and cut blooms were exhibited. In the class for six large-flowering plants Mr. W. Hall, gardener to S. Stevens, Esq., Upper Tulse Hill, well deserved the first prize awarded to him for exceedingly neat and well-bloomed plants of Mrs. G. Rundle, Mr. Brunlees, Lady Hardinge, Faust, Guernsey Nugget, and Mrs. Dixon: this last-named plant was a perfect gem, having over sixty fully expanded good blooms. Mr. John Herrington, Grove Road, Clapham Park, was placed second, and Mr. Green, gardener to F. Whitlock, Esq., third. In the class for three specimen plants Mr. Hall was again to the front, closely followed by Mr. Herrington and Mr. Livermore, who were placed second and third respectively; and for a single specimen plant Mr. Livermore gained the first prize with Mrs. Dixon, Mr. Herrington the second with Lady Talfourd, and Mr. Wells the third with Mr. G. Glenny.

Pompons were tolerably well represented both as pyramids and dwarf-trained plants. Mr. W. Hall was placed first for six dwarf-trained plants, which were a beautiful evenly grown collection, but required about another ten days to bring them to perfection. Mr. Hall also won the first prize for three standards with Calliope, Antonius, and Bob. In this class Mr. Wells was placed second and Mr. Livermore third. In the classes for six and three pyramids Mr. Livermore was awarded the two first prizes; and for three plants of Pompons not pyramids Mr. Lee, gardener to T. King, Esq., Tulse Hill, and Mr. Herrington were first and second respectively.

For twenty-four cut blooms, incurved, distinct, Mr. J. Holmes, gardener to J. Storey, Esq., Nightingale Lane, and Mr. W. Hall were awarded equal first prizes. The best blooms were Prince of Wales, Venus, Guernsey Nugget, Queen of England, Prince Alfred, John Salter, Jardin des Plantes, White Globe, General Slade, Isabella Botr, Plenipo, Cherub, Mr. Brunlees, Princess Beatrice, Empress of India, Antonelli, Golden Beverley, Barbara, Golden Eagle, Beverley, Rev. J. Dix, Mr. Haliburton, and Mrs. Dixon. Mr. G. Ottaway, gardener to T. Hepburn, Esq., was placed second with a very even stand, and Mr. Livermore third; and in the class for twelve cut blooms Mr. Lee, gardener to T. King, Esq., was awarded the first prize for a very fine collection, consisting of Princess Alexandra, Prince Alfred, Princess of Wales, Nil Desperandum, Hero of Stoke Newington, Mr. Brunlees, Mrs. G. Rundle, Lady Talfourd, Mrs. Haliburton, Rev. J. Dix, Mrs. Dixon, and Baron Beust. Equal second prizes went to Mr. W. Hall and Mr. Ottaway, and Mr. J. Holmes was third. In the class for six blooms Mr. Ottaway was first with very fine blooms of Queen of England, Prince Alfred, John Salter, Princess of Wales, Jardin des Plantes, and Lady Hardinge. For twelve large Anemone blooms, eight varieties, Mr.

Ottaway was again placed first with Lady Margaret, Empress, George Sand, Gluck, Fleur de Marie, Mrs. Pethers, Prince of Anemones, and Louis Bonamy. Mr. W. Staplehurst, gardener to Mrs. H. Walmsly, Clapham Park, was awarded the second prize, the third prize going to Mr. Livermore; and for Anemone Pompons Mr. Livermore was a good first with Antonius, Marie Stuart, Calliope, Mr. Astie, Madame Montels, Firefly, Perle, Regulus, Marguerite de Wildemar, Rouge Laine, and Aglaia; Mr. Ottaway and Mr. Wells following in the order named. Only two collections of twelve distinct blooms of Japanese were shown, Mr. W. Fisk, gardener to R. Balme, Esq., and Mr. Lee sharing the honours between them. Mr. Fisk had good blooms of James Salter, Gloire de Toulouse, Fair Maid of Guernsey, Magnum Bonum, Garnet, The Daimio, Elaine, Red Dragon, Apollo, Cry Kang, Asteroid, and Nagasaki Violet. For the encouragement of young beginners this Society has a "maiden" class for twelve cut blooms, incurved varieties, which brought three very fair collections, Messrs. Young, Gates, and Horsham sharing the honours in the order here named.

Orchids were well represented considering the lateness of the season. In the class for three plants Mr. Wright, gardener to H. Voss, Esq., Streatham, was placed first with *Phaius maculatus*, *Dendrobium formosum giganteum*, and *Oncidium trigynum*. Mr. Young and Mr. West were awarded equal second prizes, and Mr. Cherry third.

Sieve and greenhouse plants together with fine-foliage and Ferns were included in the competition, the principal prize-takers being Messrs. Wright, Kenlar, Hall, Dorset, Fisk, and Davey. Primulas were also shown by Messrs. Fullbrook, Hall, and Rockell, and the prizes were awarded in the order named.

Both Apples and Pears were plentifully shown by Messrs. Rooney, Plumbridge, Gates, Clarke, and Cherry. Some good Grapes were also exhibited, Mr. Ottaway gaining first honours for three bunches of black Grapes with Black Alicante, and Mr. Wells was first for Muscat of Alexandria. Mr. Peed, Roupell Park Nurseries, sent some very fine and well-finished bunches of Alicante, Barbarossa, and Trebbiano Grapes, not for competition, to which a special certificate was awarded; and Mr. Stevenson, Sydenham Hill, had two bunches of Black Alicante weighing 9½ lbs., also some very excellent Black Hamburgs.

Vegetables were extensively shown, and the collection from Mr. Livermore was deserving of special notice, comprising as it did nearly every production to be raised in a garden. Mr. Wright was here placed second, and Messrs. Horsham and Cocks equal thirds. In the class for eight varieties Mr. Young, Mr. Davey, and Mr. Clark were first, second, and third respectively.

SOUTHAMPTON.

The autumn Exhibition was held on the 16th inst., and was very good and crowded with visitors. Fruit and vegetables were extensively shown and in excellent condition, the competition being very keen. Messrs. Jackson & Sons of Kingston-on-Thames, were awarded the first prize for a collection of eighteen plants of Chrysanthemums, and also a first prize for twenty-four cut blooms; and Mr. Hinnell, gardener to F. Davis, Esq., Anglesea House, Surbiton, was worthily awarded the first prize in the open class for twenty-four cut blooms. Mr. Hinnell's collection were a grand lot. The Show was a great success.

EALING.

The Chrysanthemum Show was held in the school-room on the 17th inst., but was not equal to that of last year. Mr. Hart, gardener to — Nye, Esq., took the lion's share of the prizes in the gardeners' class, and Mr. Lang (an amateur) in the open classes. Messrs. C. Lee & Sons, of Hammersmith and Ealing, sent a very fine collection; also Mr. Smith of Ealing. There was a very good attendance of visitors during the afternoon and evening, which afforded sufficient evidence of the attractiveness of this popular autumn flower.

WALTON-ON-THAMES.

The Show was held on the 15th inst. in the school-room and an adjoining marquee, under the auspices of the Walton, Weybridge, Otlands, and Hersham Horticultural Society, of which H. Cobbett, Esq., is the President, and Mr. G. Masters the Secretary. The district is pleasant and salubrious, and contains a large number of mansions and villas, with attractive gardens and good gardeners, and it is pleasing to note the support that is given to the local society, and the efforts, united and harmonious, to render it and themselves as useful as possible. A considerable number of plants were exhibited, but only a few of them were of superior quality. The first prize, a silver cup, for six large-flowering plants was won by Mr. Reynolds, gardener to Mrs. Allen, Weybridge, with well-furnished plants about 3 feet in diameter. The foliage was excellent, but the blooms were not large. Mr. Millican, gardener to H. Cobbett, Esq., was placed second; and Mr. Cornhill, gardener to J. S. Virtue, Esq., Otlands, third. And in the class for four plants Mr. Boxall, gardener to J. A. Hickley, Esq., and Mr. Ploughman, were awarded the chief prizes. The plants were

generally thin and over-trained. For standards Mr. Polly, gardener to H. Rogers, Esq., Oatlands; Mr. Masters, gardener to F. Day, Esq., Oatlands, and Mr. Millican, were placed in the order named for creditable specimens, with stems about 3 feet high, and close well-bloomed heads 2 feet in diameter. Pyramids were not good—indeed, the best plants, those of Mr. Morgan, gardener to S. J. Du-Croz, Esq., were not pyramids at all, but columns. Mr. Reynolds had the best single specimen—a fine example of Hereward 5 feet in diameter. Pompons, except the half globes of Mr. Masters and the standards of Mr. Polly, were not superior; many of them were late, and others over-trained.

The cut blooms were better than the plants. In the class for twenty-four incurved varieties Messrs. Cornhill, Polly, and Reynolds were placed in the order of their names; and for twelve blooms Messrs. Boxall, Ploughman, and Morgan. The best blooms were White Globe, Blush Queen, White Venus, Mrs. Halliburton, Princess of Wales, Alfred Salter, Lady Harding, Jardin des Plantes and its bronze varieties, Golden Beverley, Barbara, St. Patrick, Pink Perfection, Prince Alfred, and Prince of Wales. The best reflexed varieties were Chevalier Domage, Dr. Sharpe, Felicite, Julie Lagraviere, Alma, Cloth of Gold, Mount Etna, and Progne, and the successful exhibitors of them were Messrs. Cornhill, Millican, and Masters. Japanese were very good. For twenty-four blooms the prizes were won by Messrs. Millican, Cornhill, and Masters with capital collections. The best sorts, and gay they were, were Elaine, Gloire de Toulouse, Yellow Dragon, Bismarck, La Nympe, Hero of Magdala, Nuit d'Hiver, Rob Roy, Fulton, and Fulgore. The best Pompons were Mdle. Marthe, James Forsyth, Florence, Bob, President, Miss Talfourd, White Trevena, and the Cedo Nullis. Messrs. Masters, Cornhill, and Polly secured the prizes with excellent stands.

Messrs. Jackson & Sons, Kingston, exhibited superior stands, including some of the newer varieties of Japanese; of these Fulton, rich yellow, and Fulgore, rosy purple, are well deserving of extensive cultivation. The Show was well managed and patronised.

STOKE NEWINGTON.

At the Assembly Rooms, Church Street, Stoke Newington, was held on the 16th inst. a very creditable Exhibition of Chrysanthemums, fine-foliaged plants, &c. For the best collection of ten Chrysanthemums in pots Mr. J. Monk, gardener to Henry Head, Esq., Stamford Hill, obtained the first honours. In this collection were two remarkable pyramids of Rifleman and Prince of Wales. They were 5 feet high and well bloomed and furnished. For six plants in 11½-inch pots Mr. Monk was the only exhibitor, staging capital examples of Golden G. Glenny, Miss Hope, Mrs. G. Rundle, Venus, Prince of Wales, and Lord Derby. The same exhibitor was first for six and four in the classes for Pompons; and Mr. F. Wells, gardener to F. A. Smee, Esq., Woodbury Down, second, but many of the flowers were not open.

For six foliage plants in pots not to exceed 12 inches in diameter Mr. Beale, gardener, Page Green, Tottenham, was first; and Mr. Monk second. For eight table plants the table was turned, Mr. Monk being first, Mr. Beale second. Both exhibited well.

CUT BLOOMS.—In the open class for twenty-four blooms Mr. Langdon, gardener to Dr. Monro, Brook House, was the only exhibitor and staged an excellent collection. In the class for twelve blooms Mr. Butcher was first. His best blooms were John Salter, Prince Alfred, and Rev. J. Dix. Mr. Monk was second in this collection. Mr. Brunlees, St. Patrick, and Princess of Wales were very fine. In the class for six blooms Mr. Butcher was first, Mr. Langdon second, and Mr. Monk third.

In the class open for amateurs residing in Hackney and Finsbury, of six blooms, T. G. Godwin, Esq., secured first honours with a fine lot. In the open class for twelve Mr. Hammond, York Lodge, Stamford Hill, was first with very good blooms, including Prince Alfred, Mr. Heales, and Princess Beatrice, remarkably good. In the class for six blooms there were five boards, first honours going to Mr. Butcher, second Mr. Hammond, third Mr. Goder, Mr. Beale and Mr. South being equal fourth.

In the maiden class for six blooms Mr. Hammond was first with very fine blooms of Prince Alfred, Mrs. Heales, White Venus, Nil Desperandum, Princess Beatrice, and Mrs. George Rundle. Mr. Oubridge, 6, Church Road, Stoke Newington, second. Noticeable on this board was White Globe and Princess Teck. Standards were very well shown by Mr. Langdon and Mr. Wells, the former exhibiting large-flowering kinds, and the other exhibitor Pompons, each receiving a first prize, which was well merited.

In the miscellaneous collections were good collections of Cyclamens from Mr. Monk, and Mr. Butcher was a very good second. A very good group of Solanums came from Mr. Rochford, Page Green, Tottenham. Mr. Stroud also exhibited a group of useful decorative plants. Mr. Shirley Hibberd exhibited some fine pans of Watercresses which he cultivates so successfully; Mr. Oubridge of the Church Road Nurseries staged very good decorative plants, also six fine plants of Elaine Chrysanthemum

and bouquets. He also had the arrangement of the Exhibition, which was very well carried out.

WESTMINSTER AQUARIUM.

The Borough of Hackney (late Stoke Newington) Chrysanthemum Society held their Show in the above building on the 20th and 21st inst. At most exhibitions of the year the cut blooms have been superior to the plants, but at the Aquarium the plants were better than the blooms. Many fine examples of culture were exhibited.

The classes for large-flowered varieties in 11½-inch pots were well filled; that accomplished grower Mr. Hall, gardener to W. Stevens, Esq., Lower Tulse Hill, having the first place in the premier class for six plants. The specimens were not more remarkable for their symmetry—the pots being nearly hidden—than for the fine foliage and excellent blooms, of which Mrs. Dixon had more than a hundred, and Faust—a grand plant—about fifty, all of exhibition quality. The second-prize plants of Mr. Rainbow were also extremely fine, but the blooms were smaller. Mrs. Dixon and Mrs. G. Rundle have each about two hundred flowers. Amongst the standards were some excellent specimens. The stems are about 5½ feet high, and the umbrella-shaped heads about 3 feet in diameter; the blooms are very regular and the foliage good. These plants reflect much credit on the successful cultivators. The Pompons were not equal to the large-flowering varieties, being generally later and more unequally furnished. The best of the reds was Bob, of yellows St. Michael, and of whites Mdle. Marthe. Messrs. E. G. Henderson & Sons, St. John's Wood, had a first-class certificate for a new variety with pale carmine red flowers, glossy and well formed; also for a small plant of a large-flowered variety named Variegata, the colour being deep rose slightly tipped with white, a variety that will be looked for when the plant becomes stronger and the flowers larger. This firm exhibited a collection of well-grown plants; and Mr. Turner, Slough, brought his grafted standards. Some of the heads were formed of half a dozen varieties, and produced a novel effect. There appears to be no more difficulty in having a number of varieties on one stem than in budding half a dozen Roses on one Briar.

Cut blooms were not very numerous nor large, yet very fresh, and many of them of excellent quality. The leading varieties will be found mentioned in our reports of other shows, and it is not necessary to repeat them. We could not wait to obtain the names of the prizewinners, the system of exhibiting under numbers and affixing the cards afterwards (now nearly obsolete), being a circumlocutory process worthy of the "dark ages," when judges were not to be trusted, and time appeared to be of less value than it is in the latest days of the nineteenth century. The old system was, however, made the best of, and the Show, a good one, was well managed by Mr. Holmes.

NOTES AND GLEANINGS.

PERHAPS the largest and most imposing display of CHRYSANTHEMUMS in England is now on view in the Victoria Park, London. The individual blooms are not finer, if so fine, as the best examples at the Crystal Palace; but the number of plants—with blooms of high average quality—exceed any collection that has this year come under our notice. Altogether five thousand admirably-grown plants are arranged under a canvas-covered framework, three thousand of the large-flowering varieties and two thousand Pompons. The canvas shed is 100 yards in length, and faces the south. It is by the side of the broad walk near the principal group of flower beds, and the plants have been inspected and admired by thousands of visitors. About a hundred sorts are in flower, and there are many splendid blooms of all the leading varieties. Gluck is especially fine and is highly effective. It is noteworthy that the plants have not had the advantage of glass to assist the opening of the blooms. It is a most successful display, and Mr. McIntyre and his assistants deserve a hearty vote of thanks for providing it. The collection will continue attractive for a week or ten days.

— We hear that Mr. George Deal, an active partner in the firm of Messrs. Weeks & Co., Chelsea, has been elected to the vacant seat in the directorate of the West London Commercial Bank, Sloane Square, Chelsea.

— The following prizes were awarded at Messrs. James Carter & Co.'s METROPOLITAN ROOT SHOW, which was held in the Agricultural Hall, Islington, last week:—Mr. Pragnell, the Gardens, Sherborne Castle, was placed first for twelve dishes of vegetables, followed by J. Neighbour, Esq.; Mr. Iggulden, gardener to R. B. Wingfield-Baker, Esq., and W. S. Baldwin, Esq., in the order named. In the Potato classes—namely, for twenty tubers of Snowflake, Red-skin Flourball, Improved Magnum Bonum, and American Breadfruit, the successful exhibitors were Mr. Pink, gardener to Lord Sondes;

Mr. Edwards, gardener to Rev. Canon Tarver; Mr. Creed, gardener to Mrs. Walton, Fernsdales; W. S. Balwin, Esq., and Mr. Hart, gardener to S. Cooper, Esq. The prizes for Onions were won by E. Thorne, Esq., and Mr. Penny, gardener to H.R.H. the Prince of Wales.

— In the absence of White Camellias, or rather the inadequacy of the supply of bold pure white flowers in Covent Garden Market, there has recently been somewhat of a "run" on WHITE CHRYSANTHEMUMS. Mrs. G. Rundle, White Venus, and other incurved varieties have been in request, but especially, perhaps, Elaine, the large pearly white Japanese variety. Good blooms have sold readily at 2s. each—not an extravagant price when it is remembered that to obtain flowers of the desired quality only three or four can be grown on each plant, which plant must have careful cultural attention for fully nine months.

— TWELVE of the Natural History and allied Societies in the midland counties have formed a union for the furtherance of the STUDY OF NATURAL HISTORY, &c. The union has decided to issue a monthly magazine to be called "The Midland Naturalist," the first number of which will be issued in January next, under the joint editorship of Mr. Edward W. Badger, F.R.H.S., Birmingham, and Mr. W. J. Harrison, F.G.S., of Leicester. The magazine will contain original articles on natural history, &c., meteorological, botanical, geological, and other notes, brief reports of the proceedings and excursions of the societies in the union, and a diary of coming meetings and excursions, &c. It is hoped that Floras of the several midland counties will in time be published in the magazine.

— THE two thousand blooms of WHITE CAMELLIAS advertised for by Mr. Wills in the Journal of last week were employed in the decorations at the Oratory, Brompton, on the occasion of the marriage of His Grace the Duke of Norfolk on the 21st inst. The floral decorations were very elaborate and extensive; besides nearly three thousand cut blooms of white Camellias, several large plants of Camellias were arranged, also Orchids, Roman Hyacinths, Nepenthes, and Ferns. One plant of Nepenthes Rafflesiana had sixty pitchers.

— MESSRS. JAMES CARTER & Co. have been awarded a Banksian medal for the excellent collection of Potatoes exhibited at the meeting of the Royal Horticultural Society on the 6th inst.

— WRITING to us on LAURUSTINUSES IN POTS a well-known floral decorator seasonably observes—White flowers are always in demand at Christmas. It is not every season that Laurustinus flowers can be depended on outdoors in December and January, but plants in pots removed to a cool house before severe weather will be sure to give a succession of bloom for a lengthened period. The plants are best established in pots, but we have frequently lifted neat little bushes in October well set with bloom and potted them in loamy moderately rich soil, and placed them under a wall or fence protected from the sun for a few days, removing them to a cool house in November, watering well, and sprinkling overhead occasionally, the reward being heads of bloom very useful for decoration and cutting from during the dull winter months. The best form is the pyramid as taking up less room than bushes, but standards are fine for breaking the monotony of flat even surfaces. All the plants require is to be hardened off after flowering, to be planted out in good soil in an open situation but sheltered from winds, and to cut the heads into shape before growth takes place, watering well if dry weather prevail when planting out; and they may be lifted again in autumn, for the lifting appears to increase their floriferous character. The flowers are much finer and more delicate when produced under glass than outdoors.

— MR. ALFRED R. WALLACE writes in "Nature" as follows on BEES KILLED BY TRITOMA. In a friend's garden here (Dorking) where there are quantities of Tritomas or "Red-hot Pokers," hundreds of bees have been this year destroyed by them. The honey produced by the flower is very abundant, and the bees enter the tube of the corolla to get at it; but the tube, which is only just large enough at the mouth, tapers gradually, and so the bee gets wedged in and cannot extricate itself.

— WE recently noticed a good plant in flower of the PANCRACTUM SPECIOSUM at the Royal Nurseries, Slough. Its large sweet-scented pure white flowers are invaluable as a centre to bridal bouquets. Introduced from the West Indies 120 years ago, it is still the best of the species, and should be in every collection of stove plants.

— WE regret to have to announce the death of Mr. SEPTIMUS HOLMES GODSON, of Rutland Gate and Tenbury, which took place on the evening of the 16th inst., at the age of 78. Mr. Godson was for many years a member of the Council of the Royal Horticultural Society, and during the whole of the period devoted himself with an energy and constancy rarely met with to the promotion of the Society's work in the direction of pure horticulture, at a time when other influences were endeavouring to make use of the Society for other purposes.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

KITCHEN GARDEN.

In nearly every garden there are annually some alterations to be made, and the best time to do this is when the pressure of work is not severe. In most gardens when the months of November and December are mild there is spare time that may be devoted to various improvements. In the first place it is of considerable importance that all the vacant ground should be dug and trenched. Not only does the garden look better in that condition, but the soil is rendered more fertile by exposure to the winter's frost; then all beds, borders, or newly-planted trees should have a mulching of manure placed round the roots before severe frost sets in. We generally wait for the first frosty night, and as the manure is all ready to wheel on to the ground it can be done when the surface is hard and clean. We have been waiting for this to place a mulching of manure on the Asparagus beds; they require a good dressing of rich cow and stable manure annually.

Besides having the quarters and borders neatly dug or trenched, the walks ought to be kept in the best order; they ought to be dry for the feet in all sorts of weather. If they are not in condition now is a good time to attend to them. We have seen the Box edging a foot high in some gardens because it had not been trimmed when it required it; and the gravel had disappeared under a coating of soil carried from the alleys by the feet of the workmen. This at least ought to be prevented by having a scraper fixed at the end of each alley where it is connected with the paths. When walks are in this state set about renovating them at once. The Box edging should be lifted and the ground prepared for replanting it. This ought to be done by taking out some of the old soil and renewing it with fresh. It is not necessary to wheel any of the soil away to do this; it can be done by digging up the ground about 18 inches wide, and during the process the soil under the Box line should be thrown on the border and the fresh soil from the border be thrown into its place. After the ground is dug tread it in firmly with the feet, then rake it level, and in the process remove any large stones that would interfere with cutting off the soil. After this has been done strain a line tightly along it; this will show any inequality in the ground, when it must be made level. When this has been done beat the ground down firmly with a spade. The soil may be cut off deep enough to allow of the Box plants being buried sufficiently to leave about 2 inches above the ground. If the old Box was bushy 1 yard will plant about 3, and if the remainder could be sold it would fetch a sufficient sum to pay for the alterations. After the planting is finished let the walks be regravelled, finishing off the work so that the middle of the path is the highest, but the middle ought not to be so much higher as to make it uncomfortable for the feet. It is necessary when the kitchen garden lies flat to drain the rain water from the path by having a row of drain tiles laid down its centre and some rough stones or bricks over it. The walk itself ought to be composed of rough stones with a coating of finer gravel on the surface. The most comfortable gravel for the feet is that which binds readily after it has been rolled or walked on for a week or so; but this will sometimes retain water on the surface, and it is not dry to the feet after rain. The best for wet weather is that from which the finer particles have been sifted, retaining only the rougher portion. It is sometimes necessary to sift it a second time to remove stones above a certain size, as large stones are very unpleasant on paths.

VINERIES.

There has been a week or more of wet weather, and this has had an unfavourable effect upon the fruit hanging in late houses. Royal Vineyard has suffered most. This variety has usually kept well with us up to Christmas and later; but it has a failing, and that is the tendency of the berries to crack near the stalk. They are worse in this respect than we ever had them, and wherever there is a crack the berry decays. All the other sorts are keeping well, including Snow's Muscat Hamburgh, Waltham Cross, Lady Downe's, Muscat of Alexandria, Mrs. Pince, and Gros Guillaume; the last-named sort is very well flavoured this season. The moisture given off from decaying leaves either lying on the ground or hanging on the Vines is a fertile source of decay, and they should be frequently removed.

Much may be done to prevent decay by heating the hot-water pipes and opening the ventilators at the right time. The pipes ought not to be heated when the house is closed, except it be to keep out frost. The heat ought to be applied after the ventilators are opened in the morning and be turned off about mid-day, which will allow of their cooling before the house is shut up in the afternoon. Vines in pots which have been started to produce Grapes in April and May should not be pushed on too rapidly until we have passed the shortest day. When the leaves are fully developed and the roots have started to grow the temperature at night may be maintained at 65°.

ORCHARD HOUSE.

The trees in pots are now plunged out of doors, where they will remain until early in January. The pots at present are merely plunged to the rim, but should frosty weather set in we shall either cover the surface of them with dry litter, or, which is equally good, some fresh cocoa-nut fibre refuse. Before this appears in print we shall probably have potted the usual number of "maiden" trees—that is, trees one year from the bud or graft, to grow on into specimens to replace any that show signs of exhaustion or which have grown unsightly. To grow fruit trees well in pots it is necessary to compress the potting material into very small compass, and it must on that account if on no other be of good quality. Good turfy maiden loam, four parts to one part of decayed manure, is as good as anything. A young tree as above may be potted into a 10 or 11-inch pot, according to the extent of the roots. It is sometimes difficult to get the roots of the largest trees into 11-inch pots. Drain the pots well and use precautions to prevent the soil from mixing with the drainage.

PLANT STOVE.

Some of the most useful decorative plants for the stove at this season of the year are those with high-coloured foliage. If we are wanting in white, yellow, and crimson-coloured flowers, there is no lack of those tints in the foliage. One of the finest, if not the very finest, of stove plants with white variegation is *Pandanus Veitchii*; it is a most free-growing plant, and can now be obtained at a very cheap rate. It should be in every collection. Then we have *Dracæna terminalis alba*, a plant destined to become very popular; *D. reginae* has broader foliage, and the leaves are very striking on well-grown plants. The finest yellows are to be obtained in *Crotons*, and when well grown nothing surpasses *C. angustifolium*; its gracefully arching foliage waves like golden streamers in the twilight, but to do it well the plant must be daily syringed with tepid water and stand close to the glass fully exposed to the noontday sun. *C. Weismannii* has the best golden foliage of any of them, and it has no tendency to change green, even when shaded. *C. undulatum* in its way is very striking, the foliage being dashed with crimson and dull purple. If crimson and purple in foliage is desired we grow *Dracænas*, and still the best are *D. terminalis* and *D. Cooperi*; the foliage is similar in colour, but that of *D. Cooperi* is recurved while the other variety is erect. There are many other foliage plants extremely useful for striking effect, and the plan's show off best over a groundwork of graceful Ferns. And what pleasing reminiscences of summer weather and sunny climes such an arrangement does produce in the dull days of November and December! Ferns that are most useful for cutting should be used, such as *Adiantum cuneatum* and *A. formosum*. This last-named species is one of the best for cutting. The fronds when mature last longer than any other Maidenhair. We have used more loam in potting *Adiantums* than formerly; indeed, we were not successful with *A. Farleyense* until it was potted in turfy yellow loam with a little decayed manure. The pretty *A. gracillimum* succeeds well with the same treatment. There are many *Adiantums* adapted for mixing with high-coloured foliage plants as well as other species of Ferns, but the four species named will be found as striking in character as any other four that could be named, and none are more useful. All such plants require a season of rest, and it is well not to excite them any more than may be necessary to keep those requiring the most heat in good health. Some of the more hardy *Adiantums* will live in a greenhouse temperature even in winter, but they will not thrive, the fronds of *A. cuneatum* becoming of a sickly yellowish green colour. The fronds last longest when cut if the plants are placed near the glass and in a temperature of about 55° in winter. Those fronds only should be cut on which the spores are nearly ripe, or as long as they remain green after that stage.

FLORIST FLOWERS.

Auriculas do not seem to take kindly to rest as yet, the high temperature at night and higher by day excites to unseasonable growth. The plants now require very little water—just enough to keep them from shrivelling. To insure neatness the decayed leaves are removed as soon as they are perceived, and no green mould or weeds should be allowed on the surface of the soil. Green fly may be brushed off with a fine camel-hair brush.

Our stock of Carnations and Picotees have now been potted and placed in frames. We admit plenty of air, and remove the lights altogether when the weather is fine. Pinks and Pansies

in beds require to have the soil stirred about them occasionally, and if the plants are thrown out by the frost to be again made firm by pressing the plants in gently by the hand.

Tulips were planted out last week. We prepare the ground by trenching and placing some good manure at the bottom of the trench, and another layer about 6 inches below the bulbs. On the surface there is a sufficient depth of turfy loam in which to plant the roots; these are placed about 3 inches below the surface of the ground. The operation ought to be performed when the ground is dry.—J. DOUGLAS.

TRADE CATALOGUES RECEIVED.

T. S. Ware, Hale Farm Nurseries, Tottenham.—*Illustrated Catalogue of Hardy Perennials, and A.B.C. Bulb Guide.*

R. Dean, Ranelagh Road, Ealing.—*Catalogue of Hardy Herbaceous and Alpine Plants, and Potatoes.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

TREE BLOWN DOWN (*F. J.*).—Unless your neighbour acted so as to cause the tree to fall upon your outhouse and fruit trees you have no remedy, any more than a man has who is wounded by a tile falling upon him from a roof.

ARBOR VITÆ (*E. E. M.*).—It is not injurious to health when growing near to a dwelling.

APPLE (*E. R.*).—The Irish Peach and Trumpington are totally different in appearance, quality, and season of ripening.

MARECHAL NIEL ROSE NOT FLOWERING (*Amateur*).—As your plant grows freely we cannot account for it not flowering; but we were in the same case once, and were told that there were two varieties. That was when it was first sent out. We immediately discarded the variety that did not succeed, and had a fresh lot budded on the Briar. The new plants have flowered freely every year since. This Rose flowers well under glass, whether it grows freely or not.

CULTURE OF VALLOTA PURPUREA IN WINTER (*A. Boyle*).—This species is evergreen, and the roots must not be quite dry, even in winter; water occasionally to prevent the soil becoming dusty dry.

VINE TO REPLACE GOLDEN CHAMPION (*A. B. C.*).—The best for your purpose is Foster's White Seedling. Duke of Buccleuch spots in the same way as Golden Champion. Unless they have special treatment they are both very uncertain.

SEEDLING BRIARS AND ROSE CULTURE (—).—Probably seedling Briars are dearer this year, but we bought them from the gentleman you name a year or two ago at 1s. 6d. per hundred; indeed, they were at that time advertised in this Journal at that price. We never "tongued" the stems of old Roses just under ground, but cut notches would probably cause roots to form near the surface. It might be done now. Cocoa-nut fibre refuse would be a poor manuring for Roses. It has very few manurial properties.

TRANSPLANTING ROSES BUDDED LAST JULY (*Idem*).—It may be done, but it is not usual to do so, as they flower much better and grow stronger if they are allowed to remain on the ground where they were budded. If it is necessary to remove them it should be done at once.

GROWING TOMATOES IN LEANTO HOUSE (*J. E.*).—There is no reason why they should not grow and bear well in such a house, but your sketch shows the pots standing on the flue. This would subject the roots to too much dry heat. It would be necessary to place a stage or inverted pot to raise the bottom of the pots about 6 inches above the flue.

PRUNING ROSES (*R. G. M.*).—Prune the Roses in the vinery as soon as growth has ceased. We should train them thinly, and should only shorten them to the extent of removing the immature tips of the shoots, as your object is to cover the wall quickly. Noisettes and Teas usually flower the more freely when not closely pruned. The Roses outdoors should not be pruned until they commence growing in the spring, cutting them then much more severely than those under glass. The Ayrshire Roses, such as *A. Bennett's* Seedling (Thoresbyana) and Dundee Rambler; the evergreen Roses such as *Felicité Perpetue* and *Flora*, also the Boursault Rose *Amadis* would cover your north wall quickly. Gloire de Dijon and the vigorous-growing Hybrid Perpetuals would also flourish admirably provided the soil is good. We cannot answer your last question.

ROSES FOR LIGHT SOIL (*E. T. H.*).—Dwarf Roses on the Manetti stock are more likely to succeed in your garden than standard Roses on Briars. Roses on their own roots would also, we think, thrive in your soil. We cannot answer your other question.

REDIGGING OLD PASTURE (*A. G. S.*).—Chop-up the buried turf and mix it with the upper surface soil.

NAME OF FRUIT (*A Reader*).—Catshead.

NAMES OF PLANTS (*M. Fisher*).—They cannot be identified from such flowerless specimens. (*W. M.*).—We cannot name florists' varieties. No. 3 is *Sericographis Ghiesbreghtiana*. (*A. T., Eshery*).—The specimens were not numbered. We do not know Canova's Laurel by that name. (*Inquirer*).—It is a *Salvia*, we think *S. Heerii*, but the specimen was much withered. (*A Reader*).—You are right as to the genera of plants. No. 2 is a *Gemma*, 3 a *Pulmonaria*, and 4 a *Saxifrage*, but we cannot name the species without better specimens.

POULTRY, BEE, AND PIGEON CHRONICLE.

POULTRY AND BIRD NEWS.

We regret very much to hear that Mr. W. A. Burnell of Winkburn Hall, near Southwell, is breaking up his Cochins yard and about to retire from the poultry fancy. We learn that all his birds are entered at the coming Birmingham Show at saleable prices, and that his poultryman is on the look-out for a fresh situation.

At the late Oxford Show Mr. S. Matthews claimed Mr. Pope's cup Black Red Game cockerel in pen 193 for £50. The purchaser exhibited this bird last week at the Crystal Palace Show and won with him the £5 ss. cup presented by Messrs. Spratt. The bird was here claimed for the enormous price of £100 10s., and has returned to his previous owner's yards at Biggleswade. Mr. Matthews consequently makes £40 and wins a cup by the transaction, the Oxford Committee made £5, and the Palace Managers £10, while the breeder loses £55 and regains his bird. May he do well with him.

We have seen specimens of the prize cards which the Oxford Committee are sending round with the prize money, and prettier ones we have but rarely seen. They are of neat size with a band of gilt and colour at the edge, and the winner's names and the prizes they have won are beautifully printed on the inside. We never remember to have seen much prettier cards save those which the Messrs. Jennison sent out from the Bellevue Show of 1873.

Of the many schedules which have come to hand that of Newtown deserves some mention, for in it we find three distinct divisions with nearly the same number of classes in each, and those, too, for the same breeds, only Division I. is for all comers, Division II. for farmers and others residing in Montgomeryshire only, and Division III. is confined to cottagers rated at £7 and under, or paying an annual rent or rents of £8 and under. We do not know how the plan will answer, but it must necessitate a large outlay in prize money and an immense amount of labour to the Judges and Committee.

At the Crystal Palace the other day a meeting was held in the Marble Hall to discuss the advisability of forming a new poultry club. A good number of fanciers were present, and the chair was taken by the Hon. and Rev. F. Dutton. After some considerable discussion the meeting was adjourned until December 3rd at Birmingham. The following are the names, in alphabetical order, of those who were appointed to draw up rules and submit them at the next meeting of the Club:—T. C. Burnell, Hon. A. Baillie-Hamilton, R. A. Boissier, O. E. Cresswell, Hon. and Rev. F. G. Dutton, A. E. W. Darby, J. Hinton, Rev. Hans F. Hamilton, R. E. Horsfall, S. Matthews, J. E. Manby, E. Pritchard, Rev. W. Serjeantson, C. Sidgwick, and R. B. Wood. Among these gentlemen are breeders of Dorkings, Brahmas, Cochins, Game, Malays, Hamburgs, Polish, French, Siklies, Bantams, and Waterfowl, so the fanciers of no particular breeds can consider themselves to be unrepresented.

On Tuesday last Mr. Albert Field dispersed the whole of the celebrated flock of Game fowls which belonged to the late Mr. Chaloner. The sale took place at the Corn Exchange, Workop, and about 125 birds were put up to auction. On the same day at Stoke Park, near Ipswich, Messrs. Sexton & Nimcoade offered about 200 head of birds from Lady Gwydyr's renowned yards. Black, Buff, and White Cochins, and Dark and Light Brahmas, were the breeds offered for sale. We do not wonder that a sale was necessary to get rid of some of the surplus birds, for when we were there in September last the park and enclosed runs seemed positively alive with healthy and good specimens.

At the coming Pigeon show to be held at Glasgow on December 19th and 20th next, under the management of the North British Columbarian Society, Capt. Norman Hill again offers for competition the £15 ss. champion Pouter cup. We hope the entries for it will be large.—W.

CRYSTAL PALACE POULTRY SHOW.

NOVEMBER 13TH-16TH.

Brahmas.—The Darks were certainly far behind the shows of 1873 or 1874 both in numbers and quality. It would be interesting to know the cause of this, whether the breed has been found disappointing as to useful qualities, or whether the great uncertainty of the produce of any but carefully selected pens has made it less popular. The Lights keep up in numbers, and have never, in our opinion, been uniformly better in quality. The cup Dark cock is a grand specimen of his owner's type of bird, well through the moult. He is like last year's cup cockerel; second too long on the leg, but in good condition; third out of condition, but nicely feathered and with a rich black breast; fourth has no cushion. The first hen is a beautifully-marked

bird of the dark colour; second very clear in breast-pencilling; third a grand-shaped bird and short on legs; fourth a bargain, entered at three guineas, well shaped, but might be clearer in marking. It was a pity that the Brahmas were placed so high up; birds of their size show to much disadvantage in such a position. The first cockerel is a beautiful bird and much such a one as Mr. Lingwood's yard has before produced for the winner; we think we have seen them with more silvery hackles. Second not so neat in head as the cup bird, well shaped, with little hackle-marking; third very dark, with rich tints, hooked; fourth coarse in head, a Cochins-like bird, but having a good cushion; we much liked the fifth; sixth a little narrow, but promising to grow. The mottled-breasted birds were very poor and scarcely worth remark; we liked the third-prize one best. Pullets did not strike us as at all equal to former years. First a silver-grey bird of fair size and well feathered; second a fine-grown pullet, promising to be a grand hen, with good even pencilling, but she is too much hooked; third too brown and not crisp enough in pencilling; fourth a small bird, good in breast, but with two styles of marking on wing; fifth short-legged and well-shaped; sixth clearly and well marked on the back, but small, and with little leg-feathering.

Light.—First in cocks was an immense bird and very white, but hollow in chest. We did not admire the second. Third would be by far the best in the class but for his ugly comb. His shape is magnificent. He is, we believe, Mr. Horsfall's cup cockerel of 1875. The first hen very good in shape and hackle; second deep and well shaped, but with a good deal of sap in her feathers; third very large but a little narrow. Among the cockerels were many poor birds, and the greater part of them were too yellow. The cup bird good all round but not large, and yellow in neck hackle; second very much hooked and yellow; we liked the fourth as well as any, though he is deficient in neck hackle; fifth intensely dark in hackle; sixth good in shape with well-marked hackle, but comb too high; seventh one of the whitest birds. Pullets made a large class of seventy. Cup a beautifully white bird with well-defined hackle; second clear in colour with a good cushion; third a compact bird, short in back; fourth hooked, and very large; fifth a good bird all round; sixth short-legged, good in hackle, hooked; seventh large but spotted. The five-guinea Selling class for Light birds was far superior to that for Dark. The first and second-prize pair were real bargains, and many other pens were by no means despicable.

Houdans were only moderate classes, save the hens, which we thought good. We must say that the awards in these classes puzzled us much. Houdan cocks apparently eat their prize cards, for we could find none towards the close of the Show. First was an indifferent bird in size with coarse comb. Second a dark and very large bird; we observed a "sold" card on his pen, his price being £10. Third a well-shaped bird. In pen 881 we observed a White Houdan cock. We thought the hens by far the best of the four classes. Four very fine birds were close together, and there was not much to choose between them. First a grand hen in shape, and evenly marked; second a little dark, but good. Mrs. Vallance's very highly commended bird had bad feet, otherwise we admired her as much as any in the class. The first cockerel is a very dark one, large and strong; second has a splendid crest and even marking, but a wry comb; third spoilt by a most irregular lumpy comb. In pullets the cup bird has a wonderfully round crest and even marking, but is a little knock-kneed; second has a very light buff with dark plumage and an ill-formed toe; third a fair evenly-marked bird; fourth very dark.

Crêves.—The cup cock is all round a magnificent bird, short on the legs, which we think a great point; he had the advantage of a corner pen. Second not equal to the cup bird, but short-legged with a good comb. Third larger and a sprightly bird. In hens Mr. Ward was again easily first. The three winners were all well worthy of their honours. We much admired Mr. Hibbert's very highly commended hen too. In cockerels first was fine and good; second a stylish bird, and a bargain; third short-legged, with a fine crest. In pullets No. 1 was easily ahead; second a good bird with compact crest; third not very large.

Hamburgs were a grand collection. Their popularity seems advancing, and several south-country breeders have been added to their admirers. Golden-spangled cocks numbered seventeen. First was a bird in which one could hardly find a fault; second generally good and lustrous, a little dark; third a good bird with an honest comb. The first hen was a lovely specimen with round even lustrous moons not too thickly set; second had also good moons, but running a little together; third more like the first, with small moons not so evenly distributed as those of the first. The first Silver-spangled cock had perfect sickle; second remarkably good for five large moons; third not a very good comb, but honestly shown. The Silver-spangled hens were a capital class of twenty-five. The cup hen was just what we admire, so even in her spangling; second almost her equal, if not quite. The Hamburg cup very justly went to Miss Mackenzie's Golden-pencilled cockerel, a bird excellent in comb and tail and even in colour, though a shade lighter than we like; we could

not understand the second award, the cockerel had such an indifferent tail; third a very rich-coloured bird. Much exception was taken to the first award in hens, but we could not see so much error in it, save that she has a badly-marked tail; second with very even and medium pencilling; third well pencilled up to the tail. The first Silver-pencil cockerel was good all round, but a little white in some of the tail feathers; second we thought a lovely little bird; third was not in good condition. The first hen was very heavily marked with real barring; second again good in pencilling, not so in comb; third small in pencilling. In Blacks the first cock was splendid in colour, but bad in comb and long in leg; second a very good bird all round; third a good old bird, his lobes wonderfully white for his age; we admired the very highly commended one. First in hens an old bird, very good in head and colour; second a very lustrous pullet; third fair in style, but knock-kneed.

Leghorns.—The judging of Leghorns must be a difficult matter, for the desired points still seem little defined. An exaggerated comb seemed here to be the first requirement for success. In Brown cocks the cup went to a bird with such a comb, generally the best in the class; the second seemed very close upon him; the third was by far the best-coloured bird, but he had the advantage of an end pen. The prize hens were all pretty-looking birds and very equal. The cup White cock was a pretty bird, but not clear. We preferred the second and third, though the latter had ugly yellow lobes.

Andalusians had two classes, one for cocks and one for hens. By some inexplicable mistake pairs were sent in lieu of single cocks in the majority of pens of the cock class, and all three prizes were awarded to them. The cockerel in the cup pen was a splendid bird; we have never seen a better. Second a very fair pair, but we did not admire the hen. Third a very good pair, but the hen too light in neck hackle. The first hen was a magnificent bird; we saw that she had been claimed, though the catalogue price was six guineas. Second we did not like nearly so well. Third fine and large, but not so even in colour as the first.—C.

Cochins.—Adult Buff cocks only brought seven pens. The winner was good in all points but colour, which was of three shades. We do not, however, see what else could have won if the Judge objected to the tendency to hock-feathering in the second. Hens were not very good. When we saw them no cards were up, and our own choice was for pen 117 (Proctor), which was subsequently second. The first hen was pretty in shape but not very good in colour; we believe she only fetched £8 5s. at the auction, which is a small price for the best Buff hen in the Crystal Palace Show. The cup cockerel was the bird which was very highly commended at Oxford, we think; we then noticed his grand style and shape, and also his want of sound and even colour. The second was of grand colour, and his only defect was his tremendous feathering. Buff pullets were pretty and the winner of a nice colour and shape, as were second and third, the latter of much the same colour as the first. The Partridges were very good. In old cocks the winner was perhaps now in the best feather, but in a short time we should think the second would run him closely, but both are good birds. All the three prize hens were very fine, the third excelling by the fashionable pencillings. Young Partridge Cochins mustered well. The winning cockerel was fully well feathered, and the pullet which won first had good size, shape, and pencillings. White cocks were very good—as superior as the cockerels were poor. The winner was in good looks with fine style and carriage, but not of the pure white we like to see. The second we put third before the cards were out; he is broad and square. Third was a great lumpy bird, heavily hocked, otherwise, in our opinion one of the best Cochins in the Show. The cup hen was very white, large, and square, and an easy winner. Second was also good. The very highly commended pen of Mr. Boissier's and the third were very even in quality, and we thought the position of the latter three birds quite a toss-up. The first White cockerel was showy but very small, and the second we think the pretty bird we saw very highly commended at Oxford. The White pullets were moderate, the first easily the winner. Blacks were very good, the first adults of Lady Gwydyr's being of beautiful colour. The winners in both cockerels and pullets may consider themselves fortunate for their honours; though both birds have good points, and although the classes were large and good, nothing stood out as easily ahead. Langshans only had nine pens, and they and their champions surprise us.

Spanish were very fairly represented in numbers and quality. From the half-score of old cocks we thought the winner well chosen; his head points were all good and his colour fair. A great many hens want more time. This Show is full early for hens of this breed, which appear to be late getting over the moult. The first cockerel, too, was good, as were the very highly commended pens of Messrs. Jones and Yates. The pullets were fourteen pens in number, and the best birds appeared to have their right positions.

Malays.—There were twenty-nine pens in the two classes,

and they consequently brought in entry fees £11 12s., and they had in prize money £8 3s., so we shall hope to see next year classes for chickens also, especially as it is hardly fair in this breed for the youngsters to compete against the parents. First and second went to good old cocks, fine in shape and possessing much bone. The third was a promising young fellow of good colour. The hens were mostly dark. The awards we did not obtain, but we fancied a bird in pen 1473 (Grimmer), 1476 (Joint), and 1481 (Hinton). We thought it on the whole as good a class as we have this year seen.

Polands.—These were extremely good classes all round. Thirteen Gold cocks opened the department, where the winner was in superb condition and seemed used to a show pen. The second was a very fair cockerel. Many birds here want four or five weeks more. Hens were fourteen pens strong, and though many birds were very good, and some especially so, we heard some difference of opinion concerning the winners. The winning Silver cock was hardly silvery enough, or else his crest is large, as is the crest of the cup hen, in fact as good as any we have seen for many shows past. Lady Dartmouth showed a good hen, and Mr. Adkins also had a beauty. The Blacks were good. We believe Mr. Dixon judged them; if so, are we wrong in saying that he this year selected birds with a different type of crest? We are not alone in our opinion; and though we quite approve of his choice, we did not think, knowing that he was to judge, that the cocks would have been placed as they were. In pen 1535 was the first-prize bird of last year. His tail is not quite perfect, but we fancy he was in as good feather this year as he was last. The first is an old bird good and well moulted; second a pretty cockerel the best part of which is his crest. In hens the second won first last year as a pullet. She has improved and appears to have more stamina, for it may be remembered we always looked on her as delicate. The first here was second last year, and second in 1875; she was grand in colour and a fine crest, the latter a shade parted. **Variety Class.**—Here was even a greater medley than usual, for two dozen pens of all breeds met to do battle for three prizes. We hope if the National next year does not increase its classification it will copy less important societies and have two firsts, two seconds, and two thirds. We are sure the present system is unfair to the Judge, who must use his own fancy however much he may try to choose the best birds. This year the first prize in the lottery fell to La Fêche, second to Sultans, and the third prize was obtained by Indian Game. The latter breed we hope, however, to see soon well established; and we say now, to give all breeders and fanciers the earliest knowledge, that classes will be provided for the variety at the Oxford and Palace Shows of 1878 if enough entries are guaranteed, particulars of which may be obtained from the Hon. and Rev. F. Dutton, or of "W." office of this Journal. Among the tenants of this class were Minorcas, Cuckoo Cochins, Frizzles, Plymouth Rocks, Dominiques, Yokohamas, Surrey Fowls, Silkies, &c. To them we offer our sympathy, and to the latter breed especially, which deserved (as far as the entries of the last Show are concerned), their class as much as ever did Silver-pencilled Hamburg cocks, ditto hens, White Leghorn cocks, and Andalusian cocks, but Silkies are not to be crushed.

Bantams.—Blacks were first in our peculiar Bantam department this time, and we hope exhibitors are satisfied. We saw one fancier and said to him, "Will the awards do for you to-day?" He replied, "What the Judges do is well." He himself was not noticed. What more can we say? If the disappointed speaks thus, surely the awards were correct, and the most lustrous, the smartest, the best won. In the White-booted class were seven entries. We hope next year to see a class for "Booted of any colour." Black, White, and Speckled. The winners were chosen for their *petiteness* we suppose, and they were a pretty little pair. In the mixed class a good pair of Dark Japanese were deservedly first. They are a charming pair, and are, we imagine, the same pair which we thought at the Alexandra hardly had their deserts; second went to Cuckoos, and third to Gold Frizzles. The Laced were very good, and we are delighted to see them more extensively exhibited. Of the awards we can form no opinion, for when we went by the cards were not on, but we should suppose the pens of Mr. Leno, Rev. W. Serjeantson, and Rev. F. Tearle would all come in for cards. The Untrimmed Classes—"The least said the soonest mended," said a poultry fancier of a score of years' standing, and so we will suffice to say that among the "Game" there were a quarter of a hundred of undubbed Game cocks, while in the next class a score of others sent representatives from their yards to show that they are able at times to show untrimmed birds. Dr. Holmes, Messrs. Newnham and Manby, Messrs. Haines, Stretch, Petter, Lingwood, Bloodworth, Borrow, Feast, Long, &c., we are amazed! The cup went to a Cochin, the second to a Black Hamburg, and the third to a Spanish. We are disappointed, and once more emphatically beg the class may next year be for "hocked Asiatics" of any breed.

Waterfowl.—Aylesbury Ducks only six pens in number—three from Aylesbury, two from Stamford, one from Wales. Kindly

understand, Aylesburianses, you are one short of the Silkies of 1876, and, on the same principle as they were, are doomed for 1878, good, however, as you all were in 1877. Rouens, on the other hand, balanced them, for they made thirty pens, and very good they were. Black Duck breeders appeared to have made one parting struggle to wrest one prize from Mr. Kelleway, and twenty-one pens were entered for the fray, but it was not to be. Then come Ornamental Waterfowl, Mandarins and Pekins, Carolinas and Muscovies—all mixed up in woeful confusion. So unkind of the Committee.

Geese were very nice. Mr. Everett seems making his mark since Mr. Cresswell was first bold enough to throw out old stagers for a new pen; second also were Grey, and third White.

Turkeys.—We had seen Mr. Howard's letter to an exhibitor to say they intended to have two Judges to award the prizes to try and avoid the repetition of last year's awards. The winners were well chosen, the first old hen being in lovely order, the first cockerel very fine, and the first young hen extremely good, large, and apparently heavy. We are requested to state that Mr. Walker did not exhibit.—W.

PIGEONS.

Barbs had six classes, only averaging seven birds a class. The cup for old birds went to an astounding Black; second in cocks was a very good Red, healthy in eye; third a Black with a capital beak, but not equal to the first in eye wattles. In hens a Yellow was easily first, a Black second, and a Red third. Young Cocks (Black or Dun).—First was a beautiful Black, apparently very young; second and third also Blacks. The winning young hens were all Blacks. But one poor Yellow put in an appearance in the class for young cocks, any other colour, and the prizes were withheld. The first hen was a Red, uneven in colour; second another Red; and third a Yellow.

Jacobins.—Red cocks numbered thirty, and were a fine class. First was a rich Red with beautiful face and an immense mane; second was small with exquisite head properties, not very good in colour; third rather large, but grand in chain and hood. We thought the first Red hen a perfect model, the prettiest in face and head we have ever seen. Second too long in beak, otherwise good. Yellow cocks were another excellent class. The cup went to the first bird in this class, rich in colour and good in every point. The first and second hens were good, but none came near the cup cock. The class for Whites brought fourteen entries. The first we thought rather large and open in hood; second very fair, but after the Yellows the hoods of the Whites do not show to advantage. The winners in the class for Any other variety were all Blacks.

Fantails.—The class of twenty-four for White cocks was marked by the Judge as "an excellent one," and most deservedly so. The first cock had an admirable tail and apparently good motion, but was too timid in his pen to show this; second and third, though hardly his equal in tail, were capital in carriage. Twenty-five White hens were shown, and the cup went to Mr. Cresswell's little bird, first in this class; she is a gem, combining motion with a perfect tail; second a large bird, but with a flat tail and good carriage; third good in tail too. The Coloured Fantails made a fair class, but with many empty pens; the winners all Blue, the first being by far the best; the second had a break in its tail; and third carried its tail too much over it. A young Black was highly commended.

Nuns made a large class, but do not appear to us equal to former days, scarcely any having the due number of coloured flights. The first, a Black, was about the only bird correct in this respect; second was a good-coloured Yellow; third a Red. Trumpeters have become a most uninteresting class. A few done-up dumpy birds win everywhere. First was slightly mottled, second Mottled, and third Black, all in points splendid specimens of the Russian type. Owls.—In English cocks the prizes all went to Blues. First is a well-known bird, second very good in frill, third very dark in colour; all these birds are excellent in head. In hens first was a pale Silver, second a lovely little Silver, and third a Blue. In the class for young birds all the prizes went to Silvers. First wonderfully good; third rather large and coarse, but good in head. The three prize birds in class for Foreign Owls were all Whites, a sweet little Black being very highly commended.

Turbits had six classes. First in Blue or Silver cocks is Mr. Ecroyd's Blue; second an old Silver, formerly known in the hands of Mr. Dear; third a Silver, which looks young. Blue or Silver hens were a small class. First was a lovely Silver; second Mr. Burnell's little Blue, with tiny beak; third a Blue, a little inclined to be dingy. Red or Yellow cocks.—First Mr. Burnell's pale Yellow, with good head; second a Red, beautiful in head and face, but not very good in colour; third a rich bright Yellow. Any other colour.—The now well-known Black Shell, which is really no Shell at all, was first; second a down-faced Black Peak; third a good White. Mr. Ecroyd's and Mr. Cresswell's Black Peaks (the latter first last year at the Palace) were strangely passed by. Hens, any other colour, were a good class, but require subdivision like the cocks. First a beautiful rich-coloured little Yellow, second a small bright Yellow with

a bad peak, third a fair Black. The little Oxford cup Yellow with a wonderful frill was not highly commended. "Hatched in 1877" were a fine class, and the judging must have been to some extent a matter of choice between colours. First was a Blue, beautiful in head and colour; second a Silver; and third a Red, with a good down face.

Maggies numbered twenty-one. First a Black, splendid in colour; the other winners also Blacks. Archangels were a very good class. All the prizes went to birds with the darker colour of head and breast. We rather regret to see very brilliant birds of a somewhat lighter hue, such as No. 3613 (Packham), unnoticed. Runts looked more unwieldy than usual; perhaps this was owing to their being judged by weight, and as a consequence in all probability fattened beforehand. Any other variety.—This class was for pairs. First were Red Frillbacks, second Joe, third Black Plain-headed Turbites, and fourth Eastern-frilled birds, Brunettes we think.

THE HONEY HARVEST IN WEST NORFOLK.

To all appearance we have been more fortunate than most of our countrymen in having had two chances, one in June and a second towards the end of July. Here, as elsewhere, the unfavourable spring left even those hives which promised well at the end of February ill provided at the beginning of the year; hence there were so many empty cells to fill up that those swarms which did issue were late. The many, with whom swarming is the only success, and who do not practise artificial swarming, lost much valuable time; but they fared better than they deserved, for some swarms which came off late in July attained considerable weight in a very short time. This was the case with my two swarms of the 20th and 21st July, the latter of which filled a 15-inch straw hive in less than a fortnight, and, calling out for more room, was accommodated with a super containing 6 or 7 lbs., which was filled and sealed up in another fortnight.

I feel sure that I was right, so far as this year is concerned, in the course I pursued of taking every advantage that offered of getting supers filled instead of taking artificial swarms in June, since between the two harvests there was a barren interval which would certainly have starved the swarms unless they had been largely fed. By supering and nading I have obtained more than 170 lbs. of honey (most of it fine honeyscomb) from four hives, two wooden and two straw, besides gaining from one of the former, which swarmed, an additional stock. More than 60 lbs. is due to one stock occupying a wooden hive only a foot square, an old Nutt's "Pavilion." Of my three other hives I may say that they have done only a little less than might have been expected of them in an average year.

A neighbour, whose apiary is near the sea, has also met with fair success. He has harvested 120 lbs. of honey from six hives and increased his stock by two. The sea lavender, like the heather, has yielded little honey this year, or no doubt he would have done still better.—E. H. R.

SIZE AND SHAPE OF HIVES—BEE MANAGEMENT.

"A KILKENNY BEE-KEEPER" asks the following questions:—1, "What is the best size for a strong stock in winter, and what height for a frame hive? 2, What advantage is there in having hives shallow in preference to having them say a foot high? 3, What is Mr. Pettigrew's system of bee-keeping?"

The first question of your correspondent is important and difficult to answer. In considering the question of sizes we arrive at "good" and "better," but who dares say which is the "best?" Many strong and valuable stocks are wintered in hives containing from 2000 to 3000 cubic inches of space. A well-made straw hive 18 inches wide and 14 inches deep is, in my opinion, "a model" of size and beauty, but I dare not venture to say that it is the best size. We have hives 20 inches wide and 12 deep, two 18 inches wide and 16 inches deep, and many only 16 inches wide and 12 inches deep, and invariably find that 18-inch hives proportionately filled with bees in autumn are as soon ready to swarm as 16-inch hives, and contain more honey; and if large hives are as soon ready to swarm as smaller ones, they are as soon ready to fill supers as are the smaller, and more able to do this when they are ready. There have often appeared statements to this effect that large hives are best for good neighbourhoods and rich pasture, and small hives are best for unfavourable localities for honey. I think such statements are without foundation and are illogical. Wherever large hives are introduced and fairly tried they carry the day, and small hives disappear.

Frame hives are generally about 9 inches deep, but some are less and some more. The bar-frame school has not yet arrived at a standard of sizes, and probably will not come to a settlement of this point for years to come. Probably hives of this kind 16 or 17 inches wide and 10 inches deep are good models.

In answer to your correspondent's second question I have to

say that there is no advantage in having hives less than a foot high. I think there is an advantage gained in having straw hives a little more than 12 inches deep. In bar-frame hives there are no cross sticks to steady and support the combs, and very few, if any, of them exceed 10 inches deep. The moveable-comb system or frame hive is now in the hands of many able bee-keepers, and doubtless will be well tested and perhaps improved in the course of a few years.

The third question comes to what is termed "Mr. Pettigrew's system of bee-keeping"—a system which I follow and recommend, which my father before me followed and improved, but the system is not ours in any sense by invention. It lived before us and should not bear our name; it belongs to the country. As this Kilkenny gentleman wants to know what our system of bee-keeping is I will try to put it before him in a tangible form and in few words.

Our aim is to get all the honey and profit possible from our bees. We use nothing but straw hives for stocks and swarms, as we have found them better for bees and combs than wooden hives, and far more easily handled and managed. Wooden hives do very well for summer weather and crowded hives, but during the autumn and winter months their inner surfaces become wet with the condensed moisture of the bees, and this condensed moisture rots much of the comb. The portions of comb thus destroyed have to be taken down and cast out and new comb built in their places. The late Mr. Woodbury, who was an honest and enlightened bee-keeper, saw for himself the evil effects of wooden hives, and afterwards had his frame hives made of straw. Some of the bar-frame school have their hives made of straw, and by-and-by many others will doubtless copy their example. Combs perish in the presence of moisture, and even straw hives if wet by rain in the winter months will cause their combs to become mouldy and rotten. All hives should be well covered and stand on boards not much wider than themselves, and the boards should be slightly bevelled so as to let the rain that may fall on them run off and outwards.

In coming to deal with general management we shall have to touch on swarming, supering, eking, nadiring, feeding, &c., for our system admits and embraces all these.

By swarming we multiply stocks and obtain hives full of fresh sweet combs and youthful queens in them, and have plenty of bees from the honey hives to strengthen the stocks and make them doubly strong to face and bear the storms of winter and do the work of spring. On the non-swarming principle queens become old and die, combs become black, tough, and pollen-bound, and the system does not provide a surplus stock of bees. On the swarming principle more bees are produced, more work done, more honey gathered in good seasons, but in unfavourable seasons the non-swarming system has the advantage. Our hives are of simple construction and free from complications, and therefore answer for all kinds of enlargement—viz., eking, supering, and nadiring. Swarming is an instinct of bees—a law of their existence and well-being. Eking is the only safe mode of enlarging hives to prevent swarming. In hot seasons neither supering nor nadiring does this with certainty.

We covet and take all the early swarms we can, for early swarms with us often attain to great weights and fill large supers in autumn. If the mother hives have had a good turn on the fruit trees they are generally pretty heavy at swarming time, and yield us a good harvest of honey three weeks after swarming. The bees are then driven into empty hives. Thus a hive yields two swarms and a harvest of honey by June. We are well satisfied with 20 and 25 lbs. of good honey from each of our early swarms. This honey sells readily here at 1s. 8d. per lb. Very well, the bees driven from their home and honey commence at once to furnish the new house and make it as comfortable as the old one. These "turnouts," for that is their name, become in good seasons healthy strong stocks for another season. The bees of the first swarm, which yields the largest harvest of honey and honeycomb, are united in autumn to the turnout, and thus it is made very strong indeed. If the weather be unfavourable for the turnouts to commence housekeeping we feed them, and we can well afford to feed them from the proceeds of their own produce. Four pounds of sugar costing 1s. made into syrup enables a swarm to make a great deal of comb, and thus make a good beginning in house-furnishing. If the weather be unfavourable for honey-gathering before swarming, the parent hives are too light to yield much honey. In such cases we do not turn their bees out, generally speaking, but occasionally take second swarms from them, for in good seasons they, like first swarms, become too heavy for stocks. Hives well filled with honey in July and August are not very eligible for keeping.

In honey seasons almost all the first swarms require more room about a month after they have been hived. If honeycomb be our aim we super; if we merely want a great quantity of run honey we enlarge the hives by ekes; if we wish to obtain both honey and an increase of stocks we use nadirs—the nadirs or bottom hives become stocks, and the top ones yield honey. If all our hives become too heavy for keeping we take the honey

from them all, putting two of the swarms into an empty hive and feeding them with syrup into a stock. In such seasons the profits of bee-keeping are great. Sometimes we out large portions of honeycomb from a hive in July, and let the bees fill-up the spaces. We have no hard-and-fast line, often dodge or start aside to modify our practice. We frequently turn our hives up to see what the bees are doing inside and what is wanted. In bee-keeping the secret of success is to have good hives. They need little attention and command the interest and attention of their owners. Success produces pleasure, creates enthusiasm, and guides bee-keepers in the right direction.—A. PETTIGREW.

OUR LETTER BOX.

SHOWING BLACK BANTAMS (*D. D.*).—The bird has no chance of success if the white is visible.

POULTRY-FEEDING (*J. W.*).—Discontinue the potatoes, and feed the birds as long as they will run after their food; mix but a little at a time, and by observing the consumption closely, you will answer the question better than we can. You should keep them at 2½d. per head per week if they have a grass run.

MAGPIE PIGEON (*Young Fancier*).—The head, neck, crop, the scapular feathers, and the tail are coloured—as black, blue, red, yellow, &c.; the rest—as the wings, the lower part of the breast and thighs—are white, and in the accuracy of their marking their value consists. The scapular feathers being dark overlay the upper part of the wings, which cause them to appear somewhat narrow. They are called, according to colour, Black Magpies or Red Magpies.

SILKWORMS (*B. Sussex*).—We are not aware that silkworms have anywhere in England been reared and managed so as to be of commercial importance. It is not usual to raise the Mulberry from seed. If you do so, the seed should be washed out of the ripe berries, preserved in dry sand, and sown in the following February.

REMARKS.

14th.—Very foggy early, fine afterwards, and bright evening.
15th.—Much warmer; wet and dull all day.
16th.—Overcast in morning, very hot sun at midday; fine night.
17th.—White frost in morning, fine day; very foggy evening.
18th.—Fine all day, but not very sunny.
19th.—Early morning fine, then dull with steady rain after 10 A.M.
20th.—White frost, fine, cold, bright day; brilliant evening.
Rather cooler, with frequent ground frosts.—G. J. SYMONS.

COVENT GARDEN MARKET.—NOVEMBER 21.

We have nothing of note to report since last week, trade being very quiet; and though the supply of outdoor goods is shorter, prices remain the same.

From observations taken near London during forty-three years, the average day temperature of the week is 48.6°; and its night temperature 30.6°.

SEASONABLE NOTES ON VINES.

VINES when properly cared for require just about as much attention when they are at rest as they do in the growing season. Of course their requirements when leafless are very different to what they are during growth; but pruning, cleaning, and surfacing the borders, are of as great importance as any summer necessity.

Excepting in late vineries, all Vines will have ripened their wood and cast their leaves by this time. After this the Vines may be pruned at any time. Cut the side shoots in to the second bud from the old wood. Young leading shoots should be cut from 2 to 4 feet from where they started this season. It is not the best plan to hurry them up rapidly, as this leaves the rods smaller than desirable. We never use styptic or any other dressing to stop the Vines from bleeding. This I believe is unnecessary, at least I have never noticed any harm follow the little sap which may be lost at pruning time. Wash the canes thoroughly with soft soap and water; but unless they are overrun with insects they need not be painted with any mixture. We did not paint one of our Vines last year, and we never had fewer insects on the Vines than during the past summer. Wash the woodwork at the same time, and when all has been cleaned thoroughly down to the border remove all the surface soil from this, and in doing so do not think that by removing the loose soil alone and replacing it with fresh will materially benefit the Vines. In many instances the Vine roots are 3 to 6 inches from the surface. If top-dressing is to benefit them it must be placed in contact with the roots, therefore it is necessary to remove the surface soil down to them, no matter how far down they may be, and then add the new compost.

Top-dressings that are only to last for one year may consist of about three-quarters of good decayed manure and one-quarter of loam; but when the top-dressing has to last for several years this compost should just be reversed, and if a bushel of ground bones can be added to every ten barrowloads of soil so much the better. When we have had no bones we have used the same quantity, or a little more, of wood ashes, which we prefer to most other ingredients. After top-dressing, if liquid manure can be had, give the border a thorough watering with it. It is a capital plan to feed Vine roots during the winter.

We stated a few weeks ago that Vine-border making was included amongst our work for this winter. We are going on with this now, as November is a good time to do such work. The way we are doing one vinery is this: The Vines are planted inside, but they have arches to come through outside. Last winter and ever since we have been encouraging them to root inside, and this they have done very fairly, so well indeed that they are independent of any outside roots. This is just what was wanted, because the outside border is cut away straight with the front upright sashes of the house. The roots

inside will support the old Vines for two years; young Vines will be planted outside in the new border in the spring. The canes will be taken through and trained up amongst the old Vines for two seasons, by that time they will be in good bearing condition. Then the old Vines will be removed to give place to the young rods without having the house a season without a crop.

The outside border is taken out 3 feet deep and 7 feet wide; 1 foot of rough stones is placed at the bottom; above this is spread all over a layer of turves about 3 inches thick, then the principal compost is put in. This consists of moderately heavy loam, with one-third of decayed cow dung added, the same of wood ashes, and about one bushel of smashed bones to every cartload of the whole. This is not trampled in, but placed about 4 inches above the right level, and it will settle down by the time the Vines are planted in spring. I said the Vine border was taken out 7 feet wide, but I must not omit saying that it is not filled up this width. In a line 5 feet from the vinery a wall of fibrous turves is built perpendicularly and firmly to the height of the border, and the chopped mixture is filled in between this and the vinery. There will be sufficient soil here for the Vines to grow in for about three years, and then another strip of soil will be taken out along the front of this turved wall, and a fresh addition added in the same way as the first one was made.

In autumn notes on Vines there must be something said on covering outside Vine borders in winter. My remarks on this subject must necessarily be brief, for, right or wrong, I never cover a Vine border in winter. I have seen far more of inferior Grapes grown when the roots were coddled-up during the winter with dry straw and wood shutters than where they were left exposed to the weather. We have top-dressed our Vine borders as directed above, and nothing more will be done to them.

With regard to starting early Vines I need say little, as with Mr. Douglas's valuable notes constantly appearing, no one need ever go wrong. Early Vines succeed best when not forced hard in bad weather, but pushed sharply on during favourable occasions.—A KITCHEN GARDENER.

CAMELLIA CULTURE.

"R. M. A." has written ably on this subject on page 386, and his remarks contain evidence of having been dictated by experience. If the practice there detailed is carried out unhealthy examples of this handsome greenhouse shrub will be less prevalent. To adopt a familiar phrase, "I go about a good deal;" my wanderings have extended over many counties, and more than once have reached "over the water"—namely, to Belgium, where they grow Camellias as freely and nearly as quickly as we in England grow Laurels. It was by noting the practice adopted in the Belgian nurseries that I was able to grow Camellias at home better than before; and yet the lesson I learned was and is extremely simple. It is a lesson that applies to all plants, and may be expressed in a few words—Feed them well and keep them clean.

"All who have Camellias under their charge not only should but must recognise the principle there laid down, or they cannot excel; and they must not only admit the importance of it, but must act on it. It is not the mere acquisition of knowledge, but the application of it that makes a man famous in his calling.

In travelling and coming in contact with various minds it is surprising to find how much latent knowledge there is in the gardening world. The unused skill—or perhaps "wisdom" would be the better word, for I imagine there cannot be skill without action, but there may be quiescent knowledge—is enormous. It is not so much a deficiency of technical knowledge as a disposition to procrastination—a hesitancy to prompt actual work, that is the chief cause of shortcomings in gardening practice. Sound knowledge and clear thought are indispensable as the stock-in-trade of every gardener, but they are not sufficient; a man must have an aptitude for work—prompt thorough work, or his attainments are rendered inert. What is the use of knowing a "bookful" if the knowledge is fruitless? A man may have a headful of technicalities, but if his hands are empty he will be left behind in this matter-of-fact world. "But what has all this to do with Camellia culture?" some may ask. My reply is that it has a very direct and important bearing on the subject, and I will state the reason why.

Not long ago I visited two gardens in which were some large Camellias. They were both in the same district, so that the fundamental nature of the soil and water is the same. In one garden the plants were in excellent health—green, clean, glossy, and the flower buds numerous and firm; in the other they were unhealthy, the foliage dingy in colour and dirty, with some scale on the shoots and the buds soft and spongy to the touch. Yet the man in charge of these unsatisfactory plants was well versed in Camellia lore. He could tell me the genus was named after Camellus, that *C. japonica* was introduced from China nearly 150 years ago, that the variety *Saccoiana* had nearly twenty synonyms, and that the plants liked plenty of shade and syringing; yet what availed all this knowledge since it was not applied to a practical end? The plants were shaded no doubt, and were syringed regularly; but the syringing as conducted did more harm than good, because it was made to compensate for a thorough sponging of the plants, and it disguised the real state of the border, which was moist on the surface but dry beneath. In a word, the plants were not clean and they were not well fed. In the case of the healthy collection of plants the man possessed little, or at any rate expressed little, historical knowledge of the Camellia, but he possessed common sense and applied it. He treated his plants, he remarked, "in the same way that the coachman did the horses"—he "groomed them well and fed them well, and had no difficulty in keeping them in good health." The system of management adopted in the case of these excellent plants appears to be identical with that described by "R. M. A."

It is not enough to know what must be done, but the necessary work must be accomplished promptly and thoroughly. Camellias require more water and support than many growers of the plants appear to be aware of. Hundreds of plants in the country are in a semi-starved state. Provided the drainage of the pots and borders is efficient it is not an easy matter to give Camellias too much water during their season of growth, and something more than pure water is very frequently necessary. On the Continent weak and clear liquid manure made from cow dung is occasionally given to the plants, and their glossy foliage tells how greatly they enjoy it. "R. M. A." has recommended, and I doubt not with good reason, Standen's manure as an excellent application for Camellias. This fertiliser is not always at hand, and I will recommend another about which there can be little difficulty in obtaining at any time—namely soot. I have found soot particularly valuable in invigorating Camellias, and imparting to the foliage that rich dark hue which so greatly enhances the beauty of the plants. Spread on the surface of pots and borders, and watered-in thoroughly, soot can be employed not only with safety but with great benefit when the plants—as so many of them do—need a stimulant. When the collection of plants in pots is limited it is advisable to mix the soot in water and to use the liquid in a clear state as being less objectionable in its application; but when the plants are in large tubs or planted in borders top-dressings of soot and copious waterings will be found an effectual mode of preserving Camellias in health, especially if accompanied by the all-import-

ant condition of perfect cleanliness of the foliage; for if the leaves are encrusted with dirt, or the stems infested by insects, no applications at the roots can act beneficially.—NOMAD.

ROMAN HYACINTHS.

As early winter-flowering bulbous plants there are none more useful than these; they are such a pure white, so sweet-scented, lasting also fairly well, and they can be had in succession from the end of October till the other Hyacinths and Tulips can be obtained. But much depends upon how the Roman Hyacinths are grown to give them their fair share of favour. For example, when planted too thinly in pots they do not give satisfaction at their flowering season. One way that they certainly show well is by having about two dozen bulbs in a pan, so that when in flower the whole is just a mass of white. That mode of growing them is not applicable to every place, but it undoubtedly shows these "lovely miniatures" to great advantage. When grown in pans they can be staked so that the whole is in good form, the spikes rising from the edge to the centre of the pan. For cutting late in the year Roman Hyacinths are very good, as at that time flowers are not numerous. These Hyacinths have doubtless lost favour by not having been grown in the way that shows them to advantage. By having only two or three bulbs in small pots, and these when in flower set round a conservatory stage, though they be fairly flowered per bulb they make little show, and cultivators from such experience may be impressed to give up their cultivation; but when planted thicker or massed together the effect is very different, and equal to that produced by any other decorative plant of the season. When they come in flower in such a dull time they last long in beauty. They require little of either skill or care for their cultivation.

If a few hundreds of bulbs are procured late in summer one-fourth of the number might then be safely placed in pans. Ordinary soil, such as is used for bedding stuff, will answer well. A succession of bulbs may be put in at the interval of a fortnight or three weeks from the time the first batch was put in, and so on till the whole importation is potted. When potted they will do well under a covering of 6 inches of sand till they have grown a couple of inches, then they may be placed in a frame or light pit. If they are wanted early they will, if put on a shelf in a stove near the glass, very soon come on and do well. Each succession can be grown in this way till all are over. Provided good bulbs are obtained there can scarcely be any failure in growing Roman Hyacinths. Ordinary soil and a fairly good supply of water, other points being attended to, will bring about success. For conservatory decoration no flowers of their kind can be produced on shorter notice.—R. M. A.

JOTTINGS ABOUT ROSES.

In scribbling about Roses it is not the easiest task imaginable to avoid the track that has already been a hundred times traversed, and yet a pile of repetitions is what all scribblers ought to avoid.

It may reasonably be considered that we have had Rose selections and elections sufficient, yet I think there is just an opening for a few lines more, and I shall endeavour to supply them. Besides growing for exhibition there are thousands who grow Roses both in large and small quantities, and perhaps there are as many more who would like to grow them, and who, to commence with, would like to have a dozen that would supply to them the greatest possible amount of pleasure, and in, perhaps, their very contracted space. For such a purpose elections for exhibition are misleading. We may have sensational blooms, but, like angels' visits, few and far between. Marie Baumann does supply us with blooms superbly charming, but then, provokingly, here in the north, without occupying some highly favoured position, she stubbornly refuses to grow. Alfred Colomb, a real king where his realm is to his liking, but in cold smoky districts his smiles are obscured; you have him careworn-like, stunted. Amongst a dozen these are not of the Roses that give most pleasure.

Some years ago, when much more enthusiastic about Roses than I am at present, I took a seventy-miles trip to Leeds exhibition to see the blooms of some new varieties, and there for the first time I saw Baronne de Rothschild, and which, adopting the alphabetical order, I shall place first in my dozen. Charles Lefebvre is also a good hardy Rose, and either of these two, if in a thriving condition, will supply blooms calculated

considerably to add to our floral queen's admirers. The Duke of Edinburgh is a most pleasing brilliant flower, and (an additional quality) is admirable for a button-hole. Général Jacqueminot, if not so full in early summer as is desirable, he will make ample amends in autumn; then he sports his real fox-hunting cloth and in more plenteous folds. Regarding Gloire de Dijon, whose name accompanies all orders, or at least all orders for the first dozen, perhaps this very popular Rose has made more Rose converts than any other Rose, and I do think that there is nothing substantial to fall back upon save downright prejudice when we see our old almost evergreen friend's name excluded from the "best" forty-eight; in bud it is unsurpassed. John Hopper you must be sure to have. He is a good-natured accommodating old boy; he comes up again and again as blithe as a bee, and year after year. Louis Van Houtte is a very fine dark Rose. For Mlle. Eugénie Verdier I have a great liking. She is robust and keeps her box of points very much to herself. Her colour was, I think, quite new when she first made her appearance. Marquise de Castellane is a noble Rose—a real gem. Prince Camille de Rohan must be had if only for a button-hole; I vote it the most satisfactory dark Rose we have. Either Princess Beatrice or Princess Louise will please, but perhaps the former is the more robust. Next comes Sénateur Vaisse. This has been the best Rose I have had this season. I believe this ends my dozen, but I find that I have not named a white; well, I like Baronne de Maynard best of all the whites, a free and charming Rose. Then we must add two Moss Roses, they are very old favourites. Procure if possible the old common Moss for one, and the white Bath Moss grows very well. I have finished my lot save one, and with reasonable fair play I believe they will supply as much delight and as few disappointments as any other dozen that can be selected, and from either the newest or the lengthiest of catalogues. Of the one alluded to, this last summer its fine blooms supplied me with much pleasure; they were the renewed pleasures of old. I tended to and nursed the old York-and-Lancaster when a child forty years ago. How distinct its stripes are still! How strange that with such a foundation we have sent our old friend into obscurity, and to this day we have not been supplied with one distinct striped Rose as a substitute.—JOSEPH WITHERSPOON, *Red Rose Vinerie, Chester-le-Street.*

SPECULATIONS AS TO THE NATURE AND ORIGIN OF THE POTATO DISEASE.—No. 3.

As bearing on the subject of the Potato murrain the next disease to be referred to is the Phylloxera which attacked the Vine, and I cannot do better than refer to the Report of the French Commissioners appointed to inquire into this subject, and make an extract from it. "For some time several large vineyards in the south of France have been visited by a formidable and entirely new disease, and to which the Vines on which it has seized succumb as a rule at the end of the second year. This disease, the origin of which is unknown, appeared for the first time in the valley of the Rhône during 1864 or 1865, but it was not until 1867 that it had attained such a prevalence as to excite alarm. In 1868 and 1869, however, it had become a regular scourge. Then it was that those wholesale desolations of wide tracts of country were seen, and which appeared to be so much the more destructive because the first appearance of the evil had perhaps been overlooked. From this time the disease did not cease to spread, and it now rages from the department of La Drome to the confines of La Crau, more particularly on poor, dry, stony, and damp soils. The visible feature most characteristic of the new disease is the existence of a centre of attack in those parts which have been but a short time affected and which extends itself without intermission. The portions of the Vine which are contiguous to the tainted part let their leaves fall and grow yellower and yellower until they are quite dried up. When the seat of contagion has grown to a sufficient extent and when the disease is severe enough, instead of one there spring up several centres of attack. From the facts it has been generally remarked that the disease is propagated in two ways, progressively and intermittently. The gradual extension of various centres of attack of which we have just spoken shows us the first; their existence simultaneously at several far isolated points is proof of the second. The concurrence of many instances has taught us that the new disease of the Vine makes its way by irregular bounds, often abruptly appearing at great distances from the already ascertained centres of contagion.

When the roots of the afflicted Vines are examined it is easy to see that they have considerably altered in their nature, for they are always soft and rotten, and the tissues surcharged and without any firmness, yielding to the pressure of the fingers. These severe affections are due to a kind of insect which has been named the Phylloxera vastatrix. This insect, which is almost invisible to the naked eye, takes up its abode in the roots of the Vine and pricks them with its proboscis in order to extract the juices they contain. These repeated performances most likely irritate the tissues and produce hypertrophy. Until now there is not a single kind of French Vine which has not been attacked by this disease, but it is reported that there are some American varieties in the outskirts of Bordeaux which, although they have been surrounded by infected plants for three years, show no signs of suffering from the new complaint. According to the recently-made investigations the Phylloxera exists under two different forms—wingless and winged; it is not viviparous, but during the whole season and under both forms it only deposits eggs. They hibernate on the root of the Vine as wingless insects, and never in the egg condition. So long as the weather is severe they remain in a state of perfect torpor, but as soon as the warmth begins to make itself felt all those individuals which the cold and damp of the winter has spared begin to wake to renewed life. They feed with great avidity, and begin to lay eggs. The increase of them soon becomes terrific and never stops till October, and it is during this time that the Phylloxera works terrible havoc."

It will be observed that here is the introduction of a new disease not observed before 1864, and that the American Vines escape the attack, and that the insect appears to exist in two forms on the leaves and underground. The disease is supposed to have been of American origin; and if it only attacked the American Vines on the leaves and for some reason or other did not attack their roots, which appears to be the case, the insect might have existed there ever since the world began without doing any serious injury to the plants, but directly the insect came into contact with European Vines and attacked their roots the Phylloxera became a new disease.

Before we have been able to find a remedy for the old Potato disease we are threatened with another—the Colorado beetle, or American Potato bug as they call it. They call everything a bug: the woolly aphis, another American production which we could have very well dispensed with, they call the mealy bug. This insect is called the Doryphora decemlineata. The meaning of the first word is Sword-bearer, and of the last Ten-lined, from the number of stripes on the body; but I believe these stripes have to be carefully examined to be able to count the number. The eggs are deposited by the female to the number of about seven to twelve hundred at intervals during forty days on the leaves of the Potato in somewhat irregularly arranged clusters. In about six days they hatch into larvæ or grubs, and feed upon the foliage of the plants from seventeen to twenty days; then they descend into the ground, and after remaining in the pupa or mummy-like state to which the larvæ change for ten or twelve days, they again make their appearance as perfect beetles. In about a week the sexes pair, and in another week the females begin to lay their eggs; hence it is calculated that they can produce three broods per annum. Mr. Townsend Glover, the United States entomologist, says that if the progeny of a single pair were to be allowed to increase without molestation for one season the result would amount to over sixty millions. There are many other interesting facts known about this beetle which have appeared in various publications, but they need not be mentioned here.

The Doryphora decemlineata does not owe its origin to spontaneous generation, neither did it suddenly arise in consequence of any peculiar electrical state of the atmosphere. It has fortunately long been known to naturalists, and was discovered more than fifty years ago feeding on a plant called Solanum rostratum, a poor relation of the edible Potato, growing on the eastern slope of the Rocky Mountains, and there it would have rested until this day but for the gradual spread of the emigrant and the cultivation of the Potato, which afforded it the means to transfer itself from the uncultivated to the cultivated flower, and from the wilds of the Rocky Mountains to the cultivated plains, and from the eastern States of America to the western States, and from the western States to Canada, and from thence to Europe.

We have now seen how a plant and various insects have lately appeared in this country and on the Continent, and how rapidly they have spread over it and the injury they have

done; and if we can only conclude that the Potato disease is caused by the fungus, and that the condition of the Potato has little or nothing to do with the origin of it, we have only to transplant ourselves in imagination to the backwoods of America, not far from the Rocky Mountains, and believe in the existence of the fungus on several allied plants of the Solanum family, and see the emigrant for the first time plant the ground with Potatoes and watch the spread of the fungus from the uncultivated plants to the cultivated, and we should then have a way of accounting for the origin of the Potato disease which is more in accordance with known facts than several of the other theories which have been advanced.—*AMATEUR, Cirencester.*

P.S.—Since writing the above I have been able to procure a copy of "The Colorado Beetle," by Dr. C. C. Riley, State Entomologist of Missouri. He refers to the Canadian Boatweed as having extended to this country, and acknowledges the American origin of the Phylloxera vastatrix, and to my very great astonishment also admits the American origin of the Oidium Tuckeri. His book is about the Colorado beetle, and he does not refer to the Potato disease, but incidentally mentions the existence of about a dozen members of the Solanum family. The only missing links in the chain now are to prove the existence of the Potato fungus on the wild plants, and show that the disease existed not far from the Rocky Mountains at an earlier period than it existed elsewhere, and the case would be complete. This I hope to be able to do on a future occasion.

STOVE VERSUS FLUE.

In answer to Mr. L. Hakeman I must remark, it seems at least retrogressive to advocate the merits of heating by flue. However, let us compare notes, and we may then probably arrive at facts. In the first place I doubt the equality of our conditions. For instance, what is the position of Mr. Hakeman's greenhouse? what does he grow (a most important question), and when do his plants bloom? My conditions are—greenhouse in the centre of a paddock exposed to the full blast of north and easterly winds. Plants grown—Gardenia, flowering in December; Stephanotis, early spring; Roses in March; Azaleas in January; Gloxinias according to time started (I am starting some now); Clerodendron Balfourii; Oranges in full bloom in early spring. The foregoing I have grown with the greatest success both as regards size of flowers and health of plants, also Allamanda, Panicum variegatum, &c. Now, unless Mr. Hakeman cultivates the same varieties or others requiring similar treatment with respect to heat, I do not see how his argument in favour of a flue (especially as it is only carried once through the house) can hold good; though I do not doubt the efficacy of his method if simply the preservation of Geraniums and ordinary bedding plants is desired.

My idea in giving my Three Years' Experience was to advocate the culture of a class of plants seldom seen or even known by the majority of those who possess a greenhouse. My thought was to open up a new field of pleasure and interest, as it has been to me.

As to economy, of course the most economical mode is that which arrives at the same end with the least expenditure of time, labour, and money. Now, the time occupied in attending my stove is about fifteen minutes in twenty-four hours; the labour is very little, fuel being close at hand; expense £2 15s. for nearly a constant fire eight months in the year. As to temperature, I must confess I do not understand the meaning of 50° average; it might mean 20° at one time and 80° at another. The only way to arrive at conclusions is to state the minimum allowed. I seldom register below 53°. One more remark and I have done. I cannot help seeing that my advocacy of this stove seems like an indirect advertisement, which practice seems to me both mean and contemptible; I will therefore add that I have since had a stove constructed on my own plan, costing less, and with twice the heating power.—*RESPICE FINEM.*

KEEPING GRAPES.

I HAVE sent you a pair of zinc tubes such as I have in use for preserving Grapes in water. A hundred of them were employed last winter and proved satisfactory; double that number will be used here this season. As the plan adopted here differs considerably in detail from that described and figured at p. 336 I will endeavour to tell your readers something about it.

A shed facing north with a flue running through it, and with ventilators at both ends, so that a draught can be had right through if necessary, is the place we have for keeping them in; and I can scarcely imagine a better place for the purpose, unless it were a dry cellar where the outer atmosphere could not much affect the temperature.

We aim to have a steady fixed temperature as near as possible with constant ventilation; indeed just what suits

ripe Grapes in a vinery suits the Grape room—an even temperature and buoyant atmosphere. But the Grape room has advantages over the vinery, for in the latter the temperature rises rapidly with the least sunshine even when the air is frosty; but the Grape room is not affected by a little sun, and its temperature only rises a little when the general temperature of the outside air becomes warmer. The safety valve is a little heat and a little air constantly; for if the place is allowed to get cold and then to rise rapidly either by sun or fire heat condensation is sure to take place on the fruit, even if the air is as dry as it is possible to make it, and decay will speedily follow. On the other hand the place may be quite damp—it may, in fact, have almost a saturated atmosphere, yet if the temperature is kept even and the air buoyant the fruit will take no harm. It is not the

Fig. 80.

amount of moisture in the atmosphere which causes damping off with fruit, flowers, and tender plants: it is the sudden rises of temperature while the fruit, flower, tender plant, or soil around it is sufficiently cold to condense the vapour which comes in contact with it. By-the-by, plants in bottom heat do not damp off at the collar.

The tubes when filled are hung up near the roof on nails driven into suspended strips of wood. They are merely filled with clear water, just so full that they will not overflow when the stems are inserted. We do not cork the neck, as we find it unnecessary to do so, neither do we place charcoal in the water, as the water will keep perfectly sweet so long as the stem of the bunch is in it; but it gets bad very quickly if the stem does not reach the water, and we find it necessary to fill up the tubes every week, for the berries absorb a good deal of the water. I have not tested with the scales the difference in weight, but I have observed that berries often become considerably plumper after bottling.

I have had Grapes bottled and hung in a vinery—i.e., I have cleared one division and hung the cut fruit in another division containing ripe uncut fruit, and it did not keep so well as it does in a shed: the stems shrivelled as if shanked. I imagine that the light caused too much evaporation. They will keep perfectly well in the dark provided all else is right; the direct rays of the sun are decidedly objectionable.

The stems must not be allowed to shrivel; they should be placed in water immediately after cutting.—*WM. TAYLOR.*

[The twin tube referred to is very similar to one (fig. 80) which was exhibited before the Fruit Committee of the Royal Horticultural Society in 1872. Mr. Taylor's tube differs in tapering from the orifice (where it is a little more than an inch in diameter and slightly flanged outwards) to the base, where it is more than 2 inches, thus increasing its water-holding capacity. It is 6 inches in length inside the fork, and is a simple and effectual appliance for suspending Grapes in water.—*EDS.*]

JOHN ROSE.

You inserted an article on John Rose in the Journal for August 5th, 1875, No. 749, which contains nearly all we can ascertain about him, except that Switzer says also Lord Essex sent him to Versailles to study the gardens there, and on his

return he was appointed Royal gardener. Yesterday (November 19th) we observed the bi-centenary of the establishment of his school on November 19th, 1677.

I am anxious to erect a brass to his memory in the parish church where he first established his school, and there may be some of your readers who would like to help in a memorial to one "of the best of gardeners" and "a religious kindly man."

—ARTHUR W. PHELPS, *Vicar of Amesbury, Wilts.*

[If any of our readers would like to contribute a trifle to a brass in the church to Rose's memory they may send to the Rev. Arthur W. Phelps, Vicarage, Amesbury, Wilts.]

MR. RICHARD SMITH'S NURSERY AT ST. JOHN'S, WORCESTER.

PART III. AND LAST.

RISEING from luncheon I said, "And now what more have you to show me?" "Show you!" replied my host, "you have only seen one-sixteenth yet." I thought and said inwardly, "I can only take a very general view of those remaining fifteen parts, then." Turning to the left from the office I proceeded along that broad, straight, central path to the trees of ornamental growth and foliage. My attention was specially attracted to certain trees, the habit of which or colour is unusual. Thus there is the Crested Laburnum, very peculiar—like Broom grafted on Laburnum. A tree resembles the head of an Australian savage, but when in bloom a golden ball, on which the eye rests permanently with pleasure. Then there is the Weeping Purple-leaved Beech, very noteworthy. T. A. Knight saw in a bed of seedling Beech the original weeping Beech found, I believe, in this nursery, and hence this variety—a case of a man having eyes and using them. A word to young men readers—first inform your minds by reading up a subject, and then with knowledge gained by book in your heads keep your eyes open and learn more. An ignorant man's eye learns little. Read and know, look and examine, and know more. For instance, Andrew Knight knew the general habit of the Beech, and so his eye noticed a peculiar growth of that tree. The next tree I noticed was the Silver-leaved Poplar, the under part of the leaf a direct contrast to its upper side. This is a most elegant and perfectly hardy variety. Looking upwards when under such a tree one seems to be looking up into a canopy of glittering silver. The Scarlet American Oaks also struck me much. I measured a leaf, it was a foot long, and the colour of Virginian Creeper. I came next upon an acre of ornamental-flowering Thorns, destined to make gay many a garden ground and light up many a shrubbery with warmth and beauty. I passed by Limes ready for avenue planting, each to be in future years "a murmurous haunt of summer bees." I marked, too, the Fern-leaved Weeping Birch with deeply incised leaf. This a very graceful and ornamental tree, a beautiful variety of "The Lady of the Woods." The Fern-leaved Lime followed, and the Aucuba-foliaged Ash, all variegated, but their colours a little rusty from the lateness of the season. Not so the *Ulmus elegantissima* with its foliage, and fine in colour—a tree thoroughly worthy of its name, with its large silver-edged leaves. I passed variegated trees of every kind. There was the *Ulmus Kaki* from Japan, singularly graceful in habit, also the *Ulmus plumosa*, plumelike, with shoots resembling a Prince's Feather; this when grown near a walk would be very telling. Among Willows there was the Babylonian, ring leaved. Coming to the end of the walk I was reminded that I was near the metropolis of Hops, for there were 70 acres of them just beyond the nursery. Having taken this view of the trees of variegated foliage and ornamental growth, I can safely say that for number, variety, and healthiness of growth I never saw their equal.

Next I am shown the houses, and in passing through them I noticed that method and cleanliness reigned supreme; all in "apple-pie" order; workmen quietly and diligently labouring inside them. Concerning the houses Mr. Smith related these anecdotes:—He proposed to his father to build a propagating house 20 feet long, and this proposal was thought extravagant. Now among the many houses above 20 there is one 365 feet long. What a difference, and what a proof of success! To show which are the popular favourites of the four thousand Vines, one-half of all here are Black Hamburgs. Of the early cooking Apples one-half are Lord Suffields, and of the Plums one-half are Victorias.

The pit ground is four acres in extent, and it has in it two acres and a half of glass, and the pits are "cram full." In a Fern house I found twenty thousand plants in pots. I noticed

in a span-roofed house, in which were fruit trees in pots, there was a Vine 200 feet and more in length, carried round just where the perpendicular sides meet the slope of the roof—a hint for those who have a greenhouse but are afraid of the flowers being injured by the Grapes. Some of the houses contained Heaths in great numbers. Then there came the Camellia houses, then those for Chrysanthemums. The cleanliness of the houses was great. Three hundred thousand grafts are put under glass during the year. In spite of this great space yet the room has to be economised. Of course the ornamental-foliaged plants in pots are very numerous in a nursery famed for trees and shrubs of ornament. There were Golden Arbor-Vitæ, variegated Ivies, Aucubas. There were seventy varieties of Ivy, some of the variegated plants singular-looking, others pretty; others, like the Ivies, beautiful. There were twenty-four varieties of Virginian Creeper; there were many pots of that singular-looking, leafless, thorny thing, the Australian Bramble. In the Rose houses all appeared healthy and good-looking. Two hundred thousand Roses are sold annually.

Among the Ferns I found a new and very unique variety of *Adiantum farleyense*, having a deeply incised leaf. This is a sport, and is not yet in trade, but will be out some three years hence and cause a sensation. There were Japanese Maples in pots, rich in colour, and suitable for dinner-table decoration; and the new weeping Wellingtonia, very choice. My attention was next directed to the herbaceous department, which I am happy to say consists of as much as two acres. I am happy to say this because at one time it appeared, in the rage for rich bedding Geraniums, herbaceous plants would cease to be cultivated. There I noticed the autumn Anemone, a very good and valuable plant, whose flowers would look charming in ladies' hair. There, too, was Ribbon Grass fit to run-up banks, while the Phlox patch was dazzling with its rich flowers.

I am next taken into the packing-shed. Oh! the heaps of crates. Oh! the size of the place for straw. As a slight indication and evidence of the amount of packing and sending off trees and shrubs at the fall of the year, I am told that $1\frac{1}{2}$ ton weight of packing string is used annually. I see the cart-stables and carpenters' shops, for all things are made for the nursery at the nursery; thus carts and trucks are built there.

I go on to the flowering-shrub patch. I see the new evergreen Privet, good in growth and colour. Conifers at St. John's are, of course, very numerous, and among them shone out conspicuous in numbers and superb beauty the *Picea nobilis glauca*. This beautiful glaucous variety is a very model of beauty whether in small specimens or large, with its sea-green and yet silvery colour, a hue hard to describe, but most pleasing to the eye. In other parts of this vast nursery I come again upon trees of ornamental foliage. Thus there is the Purple-leaved Peach with its leaves in spring of a deep red colour; then the *Wolseyana* Willow beautifully pendulous, the Golden Queen Holly, most suitable for church decoration, and a new weeping variety (strange this in a stubborn upright-growing tree like a Holly—this is beautifully weeping and variegated); and then came the Purple-leaved Weeping Birch, a contrast to the Fern-leaved: in the former, colour; in the latter, grace.

But I must draw to a conclusion. My readers will easily understand that I might have spent a week instead of a day and a half in this vast and most interesting nursery—interesting in itself and its surroundings. The fine cathedral near, the rapid Severn still nearer, beyond the Malvern Hills. All about me historic ground; close by, twice over, were battles fought. High-born cavalier and sturdy parliamentarian met and showed on either side the stuff of which Englishmen are made. Houses were once near

"Wherein the younger Charles abode
Till all the paths were dim,
And just below the Roundhead rods
And hummed a surly hymn."

Mr. Smith's nursery is an indirect proof of the prosperity and refinement of the English people of this day. In war and in rude times men had no leisure, or care, or even thought for ornamenting their parks, and shrubberies, and gardens. There might be an exception here and there, as in John Evelyn; but there are hundreds of John Evelyns now—men, aye! and women in abundance who delight in the beautiful in tree and shrub, and who lovingly regard the form and colour of leaf and flower. Gardening best prospers in quiet rich times, as now

in England. Long may they last. I can only say that my informant was right—that St. John's Nursery "is a marvellous place," and as seeing is believing, now I believe, and must add that far from being overpraised it was the opposite. Mr. Richard Smith has brought honour upon horticulture, and lives surrounded by the respect of his fellow citizens, and has himself been honoured by the Lord Lieutenant of his county.

—WILTSHIRE RECTOR.

ROSE SHOWS.

I HAVE been much interested by the letter of "ONE OF THE PUBLIC" concerning the above; but as another of the Rose-loving public I should like to know for certain whether the statement that Rose shows do not pay is correct. I remember "WILD SAVAGE" speaking (in joke, I believe) of "4d. balance sheet," but I also recollect that someone else wrote directly afterwards saying that at Hereford the balance for the last two years was £3 odd and £14 odd. If this is a specimen of the general result (financial) of Rose shows I should think they do pay. I should like to hear what the Treasurers of the National, Crystal and Alexandra Palaces, and the Aquarium have to say on this point concerning this year's shows.

As to the nurserymen, they now have two serious charges laid at their doors. Mr. Hinton says they refused to help in the elections by sending lists, and thus advertise their ability to supply the chosen Roses; and now "ONE OF THE PUBLIC" says they will not exhibit at the shows except for excessive prizes; though it remains to be seen whether the present prizes are excessive.

There is one great hindrance to metropolitan and suburban nurserymen competing at the great shows which I should like to see removed, and that is that there are no classes provided expressly for them, and they have no chance in competing with growers with pure air and superior soil. The same remark, of course, applies to amateurs. At Birmingham there used always to be classes for residents within a few miles of the town, and also one for amateurs who had never won a prize; and at Hereford there is still a class or classes for residents in that shire only. I did not see at the shows this year a single exhibit, nor do I see one of the election lists, from a less distance than ten or twelve miles from London. Now, why cannot we have a class of twelve or eighteen trusses for amateurs, some of twenty-four or thirty-six for nurserymen residing within five miles or so of the City? I believe there would be a good competition in such classes, and as I suppose all exhibitors send their friends to the shows it would increase the interest and patronage of the public. I believe the National Rose Society holds its annual meeting early next month, let them set the example in their next year's show.

I see that what I have written looks like the grumble of someone who thought he was going to win a big prize and didn't, so I may just say that I never had enough of these beautiful flowers to be an exhibitor, but am only—A LOVER OF ROSE SHOWS.

P.S.—Can any of your correspondents tell me where in the vicinity of London I can obtain the Bracken that is recommended for the protection of Tea Roses out of doors?

SEASIDE TREES IN NORTH WALES.

FOREMOST for robust and strong growth must be placed *Pinus austriaca* (Austrian Pine). This is a true seaside tree, and should be extensively planted in exposed situations near the sea. Next comes the old Scotch Fir (*Pinus sylvestris*); this also stands the sea blast well. *Pinus Pinaster* grows crooked in the stem, which is a glaring defect, otherwise it grows freely enough. *Pinus insignis* is a true seaside Pine, more inland it is rather tender. It is very beautiful; the colour is unique. These are the best of the Pines that have come under my observation along this coast. Evergreen Oak (*Quercus Ilex*) is a valuable tree for seaside planting in the most exposed places. An enormous specimen of this Oak may be seen in the gardens of Ynysmaengwyn, Towyn, Merioneth; the huge branches at the time of my visit were supported by large props of wood. This is more than a mile from the sea.

Among deciduous trees the family of *Acer* is a valuable one, *Acer platanoides* (Norway Maple) being good; also the common Sycamore (*A. pseudo-Platanus*) and its variegated varieties. The different varieties of Alder (*Alnus*) also are suitable. The Poplars (*Populus alba*, *P. macrophylla*, and *P. fastigata*) also succeed. The Turkey Oak (*Quercus Cerris*) and its varie-

gated variety may be planted on the seacoast. In my last notes I omitted to mention *Hippophaë rhamnoides* (Sea Buckthorn) as doing well near the sea. In the foregoing list I have only named those trees and shrubs as doing well of which I have cognisance. Doubtless there are numbers of other shrubs and trees growing well near the sea in other districts which would be a boon to the dwellers by the sea if they were noticed in the Journal. No doubt some of your seaside readers could kindly supply this boon.—GEORGE COOKE, Nannan Park Gardens, North Wales.

ROYAL BERKSHIRE ROOT SHOW.

ALTHOUGH Mangolds, Swedes, Turnips, Kohl Rabi, &c., do not come within the cognisance of many of the readers of the Journal, yet there are departments of the Show connected with the garden which cannot fail to be of interest, while all may like to know that this year's Show has exceeded both in quantity and quality all previous exhibitions at Reading. Her Majesty the Queen, peers, baronets, and commoners, competed for the very handsome prizes offered. Although the season has not been favourable for the production of Mangold Wurtzel, yet twelve specimens were exhibited weighing 310 lbs., the heaviest weighing 40 lbs. Marvellous specimens of Swedes, such as Sutton's Champion Swede (for the prizes in which three thousand roots were entered), Imperial Green Globe, and Purple-top Mammoth were also shown.

There is one department of the Show which has steadily been increasing in interest year after year—that devoted to vegetables; and certainly the exhibits (comprising between twenty and thirty collections) this year were such as I have not seen anywhere this season. The first prize was awarded to Mr. Wildsmith, gardener to Lord Eversley, for a collection of great merit, and the second to Mrs. Crawshaw of Caversham. The vegetables that most impressed me were the "Matchless Brussels Sprouts," which indeed deserved their name; and the Golden Savoy, beautiful in appearance and excellent for the table. The Mushrooms in Major Thoyte's collection were the most even and perfect lot that can be imagined: they almost seemed as if they had been formed in one mould, so regular were they. The Reading Onions and Sutton's Snowball Turnip were also very fine; indeed it is difficult to particularise where all were so good.

Potatoes, too, were quite an exhibition in themselves, and certainly foremost amongst them comes out Sutton's Magnum Bonum, which for symmetry, productiveness, and quality seems likely to take a permanent place. Seventy sacks have been grown on half an acre of land, the tubers having been planted in May, and when lifted were entirely free from disease. Past experience should make us very chary as to speaking of disease-proof Potatoes, but unquestionably this variety has been singularly free from it. Mr. Fenn also exhibited a collection of varieties of his own raising; and I was happy to find that he is pursuing his intelligent and scientific crossing with even more ardour, and that we may shortly expect to see something in commerce worthy of his name, as one variety has passed into the hands of the Messrs. Sutton for distribution.

A curiosity was exhibited by Professor Buckman of the Royal Agricultural College—a small root of Mangold Wurtzel displaying the tap root, which had run down to the extraordinary length of 4 feet 6 inches.

The Exhibition was honoured on Friday at the private view by His Excellency the Chinese Ambassador and suite, who were much interested in it, and partook of luncheon with the Messrs. Sutton after they had inspected the Show.—LE ROI CAROTE.

DIONÆA MUSCIPULA.

I do not in the least degree blame Mr. Douglas for the statement in the *Journal of Horticulture* for November 1st respecting the *Dionæa muscipula* and the potting of Mr. Foreshaw's plants, although I still feel the statement does me a great injustice, and if Mr. Douglas will imagine himself in my position I am sure he would feel as I do—indignant. I cannot at all understand how Mr. Black could make such a statement to a friend of twenty years' standing. I cannot speak as to what Mr. Black says about the plants being much stronger this year than they were when Mr. Douglas saw them last year. I can only say that others think differently, and I know that when I exhibited the plant at Preston in 1873 Mr. Barnes, one of the Judges, pronounced it "the finest plant ever seen." I will close by saying that as I bought the *Dionæa muscipula* and grew it from 60-sized pots into a 15-inch pan I feel I have a just right in claiming all the credit due, and especially as Mr. Black, nor anyone else, never had anything whatever to do with Mr. Foreshaw's exhibition plants

during the five and a half years I was in his service.—EDWARD PAYNE, *Florist, Fulwood, Preston.*

MR. E. PAYNE, late gardener to Mr. Foreshaw, has made several mis-statements in reference to Mr. Douglas's notes on the treatment of the above plant as supplied by me. Mr. Payne had no acquaintance with me while I held a gardener's situation; he never to my knowledge saw either the place nor the collection of plants I had under my care, consequently he did not know whether I ever grew the Venus's Flytrap or not. The "many" years he has known me is exactly four years this month.

The notes published by Mr. Douglas are the results of practical experience. Anyone who may wish to grow the Venus's Flytrap may have good results if the few directions given in Mr. Douglas's notes are followed out. Mr. Payne has exhibited a pan of *Dionæa* at the Preston Horticultural Exhibition on several occasions in good condition, being on each occasion much admired. Mr. Payne has left Mr. Foreshaw's service fourteen months back. Mr. Leazel, Mr. Payne's successor, has shown the same pan at this autumn show much finer than ever it has been seen before. I question if a pan of *Dionæa muscipula* was ever exhibited in finer condition.—L. BLACK, *Fulwood, near Preston.*

[This subject need be discussed no further.—EDS.]

CARNATION AND PICOTEE CULTURE IN BEDS.

THE following notes on the method of growing these choice varieties of florist flowers in beds have been kindly sent to me through Mr. George Rudd of Bradford from Mr. E. Adams of Swalwell, near Gateshead:—"When the ground has been well prepared by trenching I plant in November or December when the weather is favourable. Each plant must be supported by a neat stick to prevent injury from high winds, which are apt to snap off the plant close to the ground. The plants will stand any amount of frost without injury. It is a good plan to dress the surface of the beds with decayed manure from an old hotbed, which serves to steady the plants; this also serves to prevent frosts from lifting them out of the ground. Much better blooms are produced from plants put out now than in the spring. The plants do not require any more attention except tying the spindles to a stick. When the pods are nearly full I put them up on a board fixed to a post in the ground, and cover with a bell-glass. This causes the flower to open well, but it must be shaded with thin paper or muslin. When the ordinary garden soil is not suitable for the plants the beds should be made up with decayed turf from an old pasture, mixed with some sweet manure from an old hotbed or the sweepings of a cattle market, laid-up for a year before using it. Avoid pig manure, as it causes the plants to canker. Frequently stirring the surface soil in the beds is good practice, and if the plants require water give a good soaking, and do not water again until it is actually required. When the grass is layered in autumn draw some of the old soil from around the plants and replace it with turfy loam in which to peg down the layers; this gives them new vigour. Sprinkle daily to prevent flagging, and when the plants are well rooted remove them from the parent and place them in their blooming beds as before." We do not find the Carnation do well in beds in the south, but there does not seem to be any reason why they should not if they are well cultivated and as much care taken of them as our Newcastle friends seem to take of their flowers. The following are the best sorts to cultivate in beds:—*Scarlet Bizarres*: Admiral Curzon, Lord Napier, Lord Raneliffe, John Burnett, Mercury. *Crimson Bizarres*: Black Diamond, Rifleman, Isaac Wilkinson, William Murray, John Harland, Albion's Pride. *Pink Flakes*: Dr. Foster, Earl of Stamford, James Douglas, Lord Derby. *Scarlet Flakes*: Mr. Battersby, Sportsman, James Cheetham, Superb, William Harland. *Pink and Purple Bizarres*: Sarah Payne, Satisfaction; also all the rose flakes and all the Picotees.—J. DOUGLAS.

NOTES FROM CORNISH GARDENS.

MOUNT EDGCUMBE.—PART 2.

TRUE English lawns, thickly set with grass kept low and compact by frequent mowings, stretch onwards from the Italian garden along the edge of Plymouth Sound, with a boundary of shrubs well back inland, winding along in graceful curves, with an occasional fine tree or shrub group standing out in

worthy prominence upon the turf; onwards most pleasantly to wooded walks and drives, to which I must take the reader by another route. Left to myself I should probably have wandered on along the path by the sea, but the same sure guide and friend who had accompanied me in all my Cornish wanderings was there, and he pronounced it time to make for the house. Promptly following his decision came a summons to the hospitable board of its noble owner, and so my demurrer was quashed and I had to acquiesce, willingly and yet unwillingly.

On our way across the park I saw some of the turkeys, which ramble at will in the woods here, and which were, I believe, part of the only flock of what may be termed wild turkeys in this country. The flesh of these wild birds is considered superior both in delicacy and flavour to that of an ordinary farmyard turkey. Fine trees abound here—grand old Limes upwards of 100 feet in height; Beeches, Chestnuts, Oaks, Cedars, and red-stemmed Pines equally fine in their way; and a huge old Poplar must have been quite 8 feet in diameter at 4 or 5 feet from the ground. Consummate taste had evidently been brought to bear upon their arrangement, for the result now that they were old and hoary was satisfactory in a high degree. At some points dense umbrageous masses of foliage gave depth of colour and shade; at others specimens of extraordinary size stood out singly either alone, or in avenues, or in widely dispersed clumps in all the dignity and fair proportions which are found in timber trees that have sustained no check and have attained their fullest development of form as well as of stem and branch. It is such fine trees, too, that embellish a glade down which one looks from the east front of the house over the water to Mount Wise, Devonport, the rolling country beyond, and the far-off Dartmoor Tors—a singular yet not unpicturesque combination of town and country.

Other charmingly diversified views over the Sound and Plymouth open out as we proceed to the south front, where we found a flower garden worthy of especial notice for its simple yet chaste design and the happy way in which the planting was done, the centres of the beds being filled with perennials such as Heaths and Phloxes mingled with dwarf flowering shrubs, with flower belts of the ordinary bedding type around them, the effect being novel, light, and so pleasing as to be worthy of imitation. This garden is overlooked from the house and also from a stone summer house standing above it on a higher slope, for the grounds ascend somewhat abruptly here, walks winding among shrubs enclosing various lawns, out on which stand fine trees, imparting a peculiar character to each enclosure. Take for example the Cedar lawn with its eight magnificent old Cedars of Lebanon, possessing an air of dignity, repose, and striking individuality which is never found in a mixed pinetum of the ordinary type—the huge massive boles, the salver-like branches rising above each other tier above tier, the wondrous depth of green relieved so strikingly by the sunlit edges, were prominent features in every tree. Wonderful trees! worthy of the situation as it was worthy of them. My inspection of them was a brief one—a glance, a walk past beneath their dense shade, and away; but in those brief moments I received impressions deep and lasting, and learnt lessons of such value that it was only subsequently after quiet thought and close analysis that I was able to grasp their full significance. Such trees rivet the attention so thoroughly that one takes little heed of their surroundings; yet I noticed that enclosing belts of trees and shrubs lent shelter by their compact and dense arrangement, and imparted grace by the flowing curves their margin described. Without noticing the other lawns in detail I may state that all contained peculiar features—objects of uncommon size or form. One had a gigantic Lucombe Oak, another an equally fine Lime with an immense bole having curious indentures and rugged rib-like projections; another a fine Catalpa, a Tulip Tree, and a Maple side by side on a slope, all fine trees, and which for a brief period in autumn must afford a picturesque contrast, the foliage of some becoming a bright yellow and the others dying red; another an extraordinary Himalayan Bamboo (*Taamnocalmus Falconeri*), which it may be well to note is often catalogued as *Arundinaria falcata*, also a *Desfontania spinosa* about 6 feet high in bloom, but I regret to say showing incipient traces of decay. A series of such enclosures connected in an informal manner impart variety, exclude cold winds, and thus afford shelter for many a choice exotic. It is a plan worthy of adoption wherever it is desirable to lay out gardens upon high, exposed, or bleak situations.

From the house past these lawns and shrubberies a road termed the Terrace Drive winds along the face of the steep slopes of the mount, which tower high above it and sweep downwards to the sea, at some places precipitously and at others in a series of irregular undulations, along under the shade of lofty trees—very lofty trees shutting in the drive like an avenue at some places and at others opening out into glades down which are charming views of the sea; past Fern-clad banks and grassy openings fringed with an undergrowth of Rhododendrons, the pleasant greenery of which is seen on all sides among the trees. Fresh features come into view in quick succession as we drive past all too quickly: here above us towers a steep precipice with Ferns and trees clothing its face right up to the top, yonder down by the water is a fort nestling picturesquely among the trees, and not at all grim-looking; and now we enter an avenue of Ilex lofty and dense, with more Ilex clustering above them on the upper slopes, not

a formal avenue, but with occasional breaks and openings through which the sea comes fully into view far down below, and the thought involuntarily arises, Are we in England or in Italy? for surely in no other part of the world has this bright scene its counterpart, except it be on the shores of the Mediterranean. The precipitous mountain side, the Ilex avenue, the soft balmy air, the blue flashing waves alive with white sails of ships and pleasure yachts, and above all the clear bright sunny sky, all were in keeping with such an idea, which was strengthened as we drove onwards through a Pine grove consisting entirely of Pinasters—grand old trees with clean straight boles branchless from the base upwards almost to the top, presenting the aspect of just so many stately massive rugged columns, most of them probably fully 80 feet high, and many of them 4 or 5 feet in diameter. Very few of them are quite erect, almost every one leaning more or less; but then none are prostrate, and they will yet weather many of those fierce

FIG. 81.—MILTON'S TEMPLE—MOUNT EDGUMBE.

storms and sweeping gales that they have hitherto withstood so stoutly.

In the Pine grove, which extends along the slopes for a considerable distance, the road branches downwards to a pretty cottage in a snug nook by the rocky shore, and upwards through the trees to the open park, where upon the very summit of the mount and on the verge of its cliffs stands the picturesque kiosk. We enter and find an appropriate climax to our drive in the glorious view which bursts upon us as the shutters are opened. Right down below is the famous breakwater with its lighthouse and fort. Yonder lies Drake's Island, and across the Sound is Plymouth, with an irregular rugged shore and high cliffs at many points. Outside the breakwater is the open sea, and in the distance is a dark object standing up, dimly and indistinct, in a bank of mist that is stealing over the water, but even that faint glimpse is sufficient to rivet the attention, for we know that it is Eddystone. Many other objects were there, all contributing to the life and beauty of the general effect; but on these I must not dwell, nor had we much time to linger over the enchanting scene, for in the most absorbing moments that six-something train which we had to catch over the water at Plymouth would keep coming to mind, and so away down the famous zigzag walks—not driving now, right down the face of the cliffs among the trees, pausing for a few minutes to look at a curious little garden made in a snug nook apparently

excavated out of the face of the hill, rich in choice exotics—Mimosas, Camellias, Fuchsias, Olives, Aralias, and an Eucalyptus full 30 feet high, all flourishing in a state of semi-wildness, and certainly forming not the least striking feature of this wonderful place. Down, down among the trees till we are close by the sea, and along a pleasant walk which leads to the amphitheatre, a vast semicircle of lofty trees with a temple dedicated to Milton (fig. 81), containing a bust of the poet and an appropriate inscription from the fourth book of "Paradise Lost"—

"Overhead up grew
Insuperable heights of loftiest shade,
Cedar, and Pine, and Fir, and branching Palm—
Aylvan scene; and as the ranks ascend,
Shade above shade, a woody theatre
Of stateliest view."

The inscription is truthful in its application to the spot, and is as appropriate as is the temple itself, for although so near the sea and in sight of the terraces of Plymouth, yet there is an air of quiet seclusion—of stateliness that grows upon one as we pause to contemplate the singular scene, for the trees are all of extraordinary size, and impress us as being perfectly gigantic as they range upwards "shade above shade" on the steep hillside.

These notes of Mount Edgumbe must not be regarded as at all exhaustive or complete. My inspection was necessarily

a hurried one, and I have touched upon the most salient points only—sufficiently so, however, to show that the gardens, park, and woods are all very beautiful, that the situation is romantic and uncommon, singularly favourable to the growth of many exotics as well as of most native plants and trees; and it is matter for congratulation that these advantages are turned to such good account, not in a speculative manner, but with an aim and purpose worthy of the noble owner and creditable to those who so ably carry out his wishes.—EDWARD LUCKHURST.

ARALIA FILICIFOLIA.

THE plant now figured is familiar to those who have visited the chief horticultural exhibitions of the year. It is a very

state it has the appearance of a sheath, and from the centre of the leaf rises a white star-like flower, fickle in duration but beautiful in passing away. Where there is a large rockery this plant ought to have a prominent position. In the spring garden there should be one bed at least, and in the borders large patches. It is perfectly hardy in our climate, but often suffers from the cutting winds in the spring, and is all the better for having a little shelter afforded by a few branches of evergreens stuck round them. It is an acquisition in early spring in the greenhouse. *Sanguinaria canadensis* has an offspring in *Sanguinaria grandiflora*, but the only difference is in the habit of the latter being more robust and larger than the former.

They are increased by seed sown in spring in well-drained pots of rich light soil. They require care in a young state,

Fig. 82.—ARALIA FILICIFOLIA.

elegant plant, and the stems are of a deep olive colour blotched with pale green. The leaves are dark green, glabrous, twice pinnately divided, with a single lobe at the end. The pinnae are about eight in number on each side of the midrib, each one being divided nearly to the base into linear, minutely saw-toothed and spine-pointed segments. The younger leaves are more finely cut than those first formed. It forms a pretty subject for dinner-table decoration on account of its extreme elegance. This plant was introduced by Mr. B. S. Williams from the South Sea Islands, and is of free growth and easy culture.

OUR BORDER FLOWERS—POPPYWORTS.

THE Poppyworts are a numerous family. One of them is the Bloodwort (*Sanguinaria canadensis*, or puceon), named from the blood-like juice which the plant yields on being bruised. The plant has tuberous roots having red fibres, throwing up from each bend a beautiful glaucous fig-like leaf. In a young

and must be kept free from damp. A cold dry pit is a suitable place for them. They are propagated also by division in the autumn. To grow them successfully they require a free open soil; good sandy loam, and well-decomposed vegetable matter with a little peat and charcoal, suits them admirably. A moist but not wet situation will meet their requirements. They enjoy the sunshine, but will bear partial shade.—VERITAS.

CONCERNING ROSES.

"WHAT Roses shall I buy?" (page 378). Buy good Roses that will grow, bloom well and freely, and live on. Buy out of the list on the page quoted Baronne de Rothschild, Madame Victor Verdier, Charles Lefebvre, Alfred Colomb, Marguerite de St. Amand, Dr. Andry, Marquise de Castellane, Comtesse d'Oxford, Sénateur Vaisse, and Duke of Edinburgh. Add these, or some of them: Star of Waltham, Madame C. Joigneaux, Gloire de Dijon, Céline Forestier, Triomphe de Rennes—three of the best in the Rose kingdom—Edward Morren,

Jules Margottin, Vicomtesse de Vezins, Pierre Notting, Maxime de la Rocheterie, La Ville de St. Denis, Mdle. Marie Rady, Princess Mary of Cambridge, Baronne Prévost, Dr. Jamin, William Griffiths, Pierre Letetzky, Paul Neyron, Lord Clyde, Baronne Adolphe de Rothschild, Abel Grand, Duchesse de Caylus, Maurice Bernardin, Fisher Holmes, Madame C. Wood, Mdle. Annie Wood, Prince de Portia, Maréchal Vaillant, Souvenir de la Reine d'Angleterre, Felix Genere, Comtesse Cecile de Chabillant, John Hopper, Duchesse d'Orleans, and Prince Camille de Rohan. The above are Hybrid Perpetuals, and are all good.

Bourbons.—Acidalie, Souvenir de la Malmaison, Sir Joseph Paxton, Baron Gonella, and Baronne de Maynard—a lovely Rose, always in bloom.

China.—Mrs. Bosanquet.

Two of the finest Roses are Louis Van Houtte and Maréchal Niel, but they are not generally recommendable for the public.

Do not buy these; they are generally bad growers, but beautiful: Marie Bauman, Francis Michelon, Emilie Hausburg, Marquise de Mortemart, Mdle. Marie Cointet, Horace Vernet, and Mdle. Bonnaire. If you cannot get straw you cannot have corer.

Do not go to shows to choose, but go to the nurseries or the gardens of large growers. The election would deceive the elect! Look at the positions of some in the election—Gloire de Dijon, 59; Pierre Notting, 38; Maurice Bernardin, 59; Madame C. Joigneaux, 70. They are four of our best Roses! W. F. RADCLIFFE, *Okeford Fitzpaine*.

AUTUMN SHOWS.

AMONG exhibitions which have recently been held we are able to furnish reports of the following:—

KINGSTON-ON-THAMES AND SURBITON CHRYSANTHEMUM SOCIETY.

This newly organised Society held its first Exhibition at the Drill Hall, Kingston, on the 21st and 22nd inst., and was a decided success. The Drill Hall is a very large building, admirably adapted for a show, but requiring extensive collections to occupy the space ornamentally, which, owing to the Society having no limited radius, was easily effected, and the competition was in most of the classes very spirited.

Prizes were offered for groups of an unlimited number of Chrysanthemum plants to fill a space of 50 square feet, which brought together four collections; and to Mr. W. Bates, gardener to W. H. Punchard, Esq., Twickenham, the post of honour was awarded for a collection very tall but of first-rate quality. Mr. J. W. Moorman, gardener to the Misses Christy, Coombe, was a remarkably close second with plants dwarfier in habit and effective. Mr. Cornhill, gardener to J. S. Virtue, Esq., Weybridge, was placed third. In the class for six trained specimens Mr. Beckett, gardener to J. McConnell, Esq., Esher, exhibited an admirable collection, and was deservedly awarded the first prize for well-grown examples of White Venus, Guernsey Nugget, Mrs. G. Rundle, Bronze Jardin des Plantes, Venus, and Mrs. Sharp. Mr. Cornhill, and Mr. Ploughman, gardener to J. Wilkes, Esq., Weybridge, were second and third respectively; and in the class for four specimens Messrs. Masters and Boxall of Walton shared the honours between them. Trained standards were not plentifully represented, and Messrs. Masters, Cornhill, and Boxall were the only contributors.

Cut blooms were very numerous shown in the different sections, and were above the average of the present season. Six competitors entered the class for twenty-four incurved varieties distinct, and the first prize fell to F. Wildman, Esq., Camberwell, for a well-finished and neat collection comprised of Prince Alfred, White Globe, Nil Desperandum, Guernsey Nugget, Prince of Wales, Jardin des Plantes, Queen of England, Venus, Mrs. Mary Morgan, Beverley, John Salter, Princess of Teck, Hero of Stoke Newington, Golden Beverley, Lady Slade, Mrs. G. Rundle, Mrs. Dixon, General Bainbridge, Mrs. Halliburton, King of Denmark, Eve, Princess of Wales, Empress of India, and Mr. G. Glenny. Mr. Cornhill was here placed second; Mr. McPherson, gardener to S. Page, Esq., Surbiton, third; and an extra prize was awarded to Mr. Moorman. In the class for twelve cut blooms eleven collections were staged, and to Mr. Hinnell, gardener to F. A. Davis, Esq., Surbiton, the Judges awarded the first prize; Mr. Bentley, gardener to Sir T. Gabriel, Wimbledon, the second; and so exceedingly good were others, that prizes were awarded to Mr. Masters, Mr. Boxall, and Mr. Ploughman in this class.

Japanese varieties were extensively shown and very good. Messrs. Hinnell, Moorman, and Cornhill were placed in the order here named for twenty-four varieties, and Mr. Beckett, Mr. McPherson, Mr. Bentley, and Mr. Boxall for twelve, while Mr. Attrill and P. Sutton, Esq., shared the honours for six varieties. We have not seen the Japanese varieties shown in

greater numbers or in better order anywhere this season than at Kingston. They make a very attractive display, and deserve further encouragement. The best of the varieties shown were Fair Maid of Guernsey, Elaine, Bronze Dragon, James Salter, Red Dragon, Rob Roy, Chang, Gloire de Toulouse, Sultan, Meg Merrilees, Ne Plus Ultra, Oracle, Fulgore, Fulton, Striatum, and Grandiflorum.

Mr. Moorman was awarded the first prize for twelve reflexed Chrysanthemums with good blooms of Triomphe du Nord, Dr. Sharp, Cloth of Gold, Christine, Monsieur Lucien Barthéle, &c., and Mr. Beard and Mr. Cornhill were placed second and third; and in the class for twelve Anemones Messrs. Cornhill, Masters, and Moorman were placed in the order named. Several collections of Primulas, dinner-table plants, Cyclamens, and berry-bearing plants were staged, for which numerous prizes were offered. These plants, associated with the cut flowers, contributed materially to the general effect.

Messrs. Jackson & Sons contributed an extensive bank of stove and greenhouse plants, which formed one of the most attractive features of the Show. It was comprised of Tree Ferns, Palms, Dracænas, Crotons, &c., having Chrysanthemums, Orchids, and Heaths interspersed; they also exhibited several superior stands of cut blooms, including some very choice sorts; and Mr. Beckett an interesting collection of Geranium blooms. The show of fruit was limited. Mr. Hinnell also contributed a similar though somewhat smaller collection. Mr. Jackson, jun., who is the Honorary Secretary, is to be congratulated on the success of the Show, but another season it would be well to have a regulation standard for size of boards on which to show the cut blooms, and the effect of the Exhibition would thereby be much enhanced.

MAIDSTONE.

The Mid Kent Chrysanthemum and Fruit Show was held in the Corn Exchange on the 21st inst. Good as were the Chrysanthemums, the remarkably fine collection of Apples, Pears, Grapes, &c., was, perhaps, even more commendable, and the numerous special prizes awarded testified pretty plainly to the Judges' appreciation of this department of the Show. The large central stand in the Concert Hall was entirely occupied by Apples. Mr. L. A. Killick of Langley took the chief honours here, and was awarded a special prize for a separate box, which was in every way deserving of the distinction. Roger Leigh, Esq. (Mr. Haycock, gardener), was a successful exhibitor both of Apples and Pears. The Grapes formed a small but good class, Mr. C. Neve standing first with Black Hamburgs, and Messrs. T. & J. Hollingworth dividing the rest of the honours with Lady Downe's, and Madresfield Court. Some Grapes grown in the open air by W. Moore, Esq., of Wierton, were also deserving of especial notice. The floral contributions of Mr. S. Hubbard of Marden, and of Mr. Cannell and Mr. Frost, nurserymen, agreeably relieved the appearance of the tables in different parts of the Hall.

The prizes for ten large-flowering Chrysanthemums in pots were awarded to Mr. J. W. Braddick, Rev. C. Shepherd, and Rev. J. Stuart Robson, in the order named. For six plants of the same nature, first Mr. C. Neve, second Mr. J. Clabon; the Rev. J. Stuart Robson and Major Best equal thirds. The prizes for ten large-flowering standards were awarded to Rev. J. Stuart Robson and Rev. C. Shepherd. Cut blooms.—Twenty-four large-flowering, distinct varieties, first prize (silver cup), Mr. J. W. Braddick, second Rev. J. Stuart Robson, third Mr. Davis, Maidstone Cemetery. Twelve cut blooms, first Mr. J. W. Braddick, second Mr. Davis, third Mr. C. Neve.

For nine plates of distinct varieties of dessert Apples, first Mr. Roger Leigh with Ribston Pippin, Cox's Orange Pippin, Melon Apple, King of the Pippins, Braddick's Nonpareil, Manington's Pearmain, Blenheim Orange, Royal Russet, and Cornish Aromatic; second Mr. William Skinner with Cox's Orange Pippin, Ribston Pippin, King of the Pippins, Scarlet Pearmain, Court Penda Plat, Summer Golden Pippin, Warwickshire Pippin, and Golden Knob; third Mr. A. Warde. For three plates of dessert Apples, first Mr. F. Smith with Manington's Pearmain, Mabbott's Pearmain, and Cox's Orange Pippin; second Mr. A. T. Killick with Golden Knob, Warwickshire Pippin, and Ribston Pippin; third Major Best. For nine plates of distinct varieties of kitchen Apples, first Mr. W. Skinner with Belle Dubois, Blenheim Orange, Wellington, Cullen, Stone Apple (Loddington Seedling), Bedfordshire Foundling, Castle Major, Beauty of Kent, and Hanwell Scouring; second, Mr. R. Leigh with Belle Dubois, Belle Josephine, Wellington, Blenheim Orange, Linnaeus Pippin, Reinette du Canada, Calville Rouge, Calville Blanche, and Calville St. Sauveur; third, Mr. A. Warde. For three plates of kitchen Apples, first Mr. L. A. Killick with Loddington Seedling, Wellington, and Blenheim Orange, who had also the second prize with Wellington, and Winter Quoining; third Mr. J. Weld. For three plates of dessert Pears, distinct varieties, first Mr. R. Leigh with Duchesse d'Angoulême, Beurré Diel, and Triomphe de Judoigne, second Mr. J. W. Braddick. For three plates of kitchen Pears, distinct varieties, first Mr. J. W. Braddick.

CROYDON.

It is only a few weeks since the first mooting of an autumn show was hinted at in this locality, and considering the short notice a very good display was arranged at the Public Hall on the 22nd and 23rd inst. Specimen plants were not equal to others we have seen this season, but the cut blooms, also fruit and vegetables, were very good indeed; in fact the vegetables were the finest we have seen this season with the exception of some collections at the Crystal Palace in September.

The principal contributors of specimen plants were Mr. King, gardener to Stephenson Clarke, Esq., the President of the Society; Mr. Brett, gardener to Mrs. Charlton, Mitcham; and Mr. Jupp. For twenty-four cut blooms incurred, distinct, Mr. Orchard, gardener to F. W. Harris, Esq., Coombe House, Croydon, was awarded the first prize for a very neat and superior collection of White Globe, Princess of Wales, Jardin des Plantes, Queen of England, Princess of Teck, Prince of Wales, Mr. Bunn, White Venus, Eve, Capitata, Miss Mary Morgan, Lord Derby, Golden Beverley, Mr. Gladstone, Venus, Empress of India, Prince Alfred, Mrs. Halliburton, General Bainbridge, George Glenny, Abbé Passaglia, Mrs. G. Rundle, Le Grand, and Mrs. Dixon. Mr. King was a very good second, and Mr. Neal, gardener to E. Wormald, Esq., third with a very good collection. In the class for twelve Mr. Orchard was again to the front with good blooms of some of the varieties above named, and Mr. Neal and Mr. Brett second and third respectively. Mr. Chaff, gardener to C. H. Goschen, Esq., Shirley, staged a board of six admirable blooms of Jardin des Plantes, Princess of Teck, Queen of England, Bronze Jardin des Plantes, White Venus, and General Bainbridge, to which the first prize was awarded. Japanese blooms were contributed by Messrs. Neal, Orchard, and Brett, and the prizes awarded in the order named. Anemone blooms came from Messrs. Brett and Neale, and Anemone Pompons from Mr. Brett and Mr. King.

Mr. King was awarded the first prize for four Orchids with very fair examples of *Vanda tricolor*, *Cypripedium insigne*, *Calanthe vestita* oculata, and *Veitchii*. Several collections of Primulas were staged; the prizes were awarded to Messrs. Price, Brett, and King in the order named. Prizes were also offered for Poinsettias, the best coming from Mr. Neal, Mr. King, and Mr. Chaff, who were first, second, and third respectively.

Mr. Charman, gardener to C. W. Bond, Esq., received the first prize for a collection of fruit, and Mr. Chaff the first prizes for Muscat of Alexandria and Black Prince Grapes, Mr. Neal being awarded the second prize in both cases. An extra prize was awarded to Mr. Stephenson, gardener to F. Peck, Esq., for very fine Black Alicante Grapes. Apples were sent by Messrs. Chaff, Walker, and King, who were the prizetakers in the order named.

Nine collections of vegetables were staged, all of extraordinary merit. The first prize was awarded to Mr. Chaff for excellent examples of No Plus Ultra Peas, Walcheren Cauliflower, Sorymer's Brussels Sprouts, three sorts of Cabbages, Parsnips, Spinach, fine Veitch's Red Globe Turnip, Beet, Onions, Early Horn Carrot, Tomatoes, Paterson's Victoria Potatoes, &c. Mr. Orchard was placed second with a very good collection containing some very fine Cardoons, and Mr. Brett third. Several other exhibitors were highly commended, all showing well.

Messrs. Rollisson & Sons of Tooting sent a group of Chrysanthemums, which had a very pleasing effect; and Mr. King, gardener to Stephenson Clarke, Esq., contributed a very fine bank of fine-foliaged plants, completely filling the spacious platform of the Hall with Palms, Dracæas, very large *Adiantums* farleyense and scutum, the whole edged with *Erica gracilis* and *Panicum variegatum* mixed. To Mr. W. P. Robinson, the Secretary, is due in no small measure the success of the Show.

DARTFORD.

The seventh annual Show of the Dartford Chrysanthemum Association was held at the Victoria Assembly Rooms on the 21st and 22nd inst., and was quite equal if not superior to its predecessors. Specimen plants were very good, and were shown principally without that bad training the Chrysanthemum is so much subjected to. The display of cut blooms was also exceedingly good, an amateur (Mr. Hards) outstripping all the gardeners both for size and quality. His collection of twelve blooms were the best we have seen this season, and comprised very fine examples of Lady Hardinge, Empress of India, Golden Queen, White Globe, Queen of England, Prince Alfred, Barbara, Mrs. G. Rundle, Mrs. Dixon, Mr. G. Glenny, Nil Desperandum, and Prince of Wales. Mr. Hards practises the once-potting system, and removes his plants from a small state to a large one without any intermediate change; to this he attributes his success. Many other creditable collections deserve notice, but our space will not allow us to particularise them; suffice it to say it was altogether a good Show, and well managed by Mr. Skelton.

DIDSBURY.

This, the third annual Show of the Society, was held on the 24th inst. One of the prettiest plants to be seen at this season was exhibited—namely, a specimen of *Cattleya Trianie* with

seven spikes of beautiful rosy flowers. This was sent from the collection of G. Gottschalke, Esq., Fallowfield. Amongst the Chrysanthemums in pots it might be observed that the varieties of Cedo Nulli are yet unsurpassed for free flowering and general usefulness. For the best six Primulas, three red and three white, T. Ashton, Esq., showed a very fine set, doing credit to his gardener, Mr. Johnson. Epiphyllums were a good feature in this Show, the best being contributed by C. Blackburn, Esq. These plants are most showy in their season, either as small plants for table decoration or as large plants in the conservatory, and they are capable of being grown in so many ways, such as high or dwarf standards on the *Cereus* stock. There was a good competition for six pots of Roman Hyacinths in pots not exceeding 7 inches, about fourteen bulbs being grown in these sized pots. The first-prize Grapes—white, which were Muscat of Alexandria, and black, which were Alicante—were shown by D. Adamson, Esq., doing credit to his gardener, Mr. Brierley, who is also Secretary for the Society.

Amongst table plants, which were shown in half-dozens, the most chaste one in flower was an *Ixora Coleii*, about a foot high with seven heads of pure white flowers. This was in the first-prize stand, which was contributed by—Morris, Esq. Amongst foliage plants in this class *Cocos Weddelliana* and *Aralia Veitchii* were the most elegant. For the best four exotic Ferns J. Boland, Esq. (J. Fletcher, gardener), was first with four choice kinds and good specimens.

For the best eighteen cut blooms of large-flowered Chrysanthemums, which was the main feature of the Show, and in which there was a very good competition, Miss Ashton was first (H. Royle, gardener). The varieties were Prince Alfred, Golden Beverley, Novelty, Fingal, Princess of Wales, Prince of Wales, White Beverley, Mr. Howe, Lady Slade, Nil Desperandum, Jardin des Plantes, Miss Mary Morgan, Baron Beust, Golden Nugget, Queen of Beauties, Mrs. Halliburton, Lady Salford, Mrs. G. Rundle. This last-named kind next to the white Cedo Nulli might be said to be *AI* for pot culture for conservatory work. In the classes of twelve and six cut blooms D. Adamson, Esq., was the successful exhibitor.

For a collection of six distinct dishes of vegetables C. P. Henderson, Esq. (W. Oakes, gardener), was first with a good tray, in which were fine heads of Cauliflower, Mushrooms, Brussels Sprouts, &c. An honorary exhibit of eighteen cut blooms (Chrysanthemums) were by Mr. Faulkner, Woolton Hall, Liverpool, to which an extra prize was awarded.

FLOWER SHOWS, GENERAL AND SPECIAL.

As surely as ventilation, water supply, charity organisation, or some other subject crops up in the dead season in the *Times*, so when gardens are comparatively empty, plants at rest, and the days dull, does the subject of flower shows occupy the columns of the horticultural press. Faults are found, "high falutin" indulged in, suggestions made, and after all we fall back into the same grooves as before.

As "ONE OF THE PUBLIC" has given us his views anent Rose shows, may I be allowed to take a little wider range, and from the experience of many years in many places to express my views? I desire "nothing to extenuate or set down aught in malice;" there are only two flowers which I ever exhibit, and the Rose is not one of them, and I hope therefore to give an impartial view. Before entering on it may I be permitted to say, in reference to your correspondent's remarks at the close of his letter, that I have had the pleasure of the acquaintance of most of the leading nurserymen of the United Kingdom, and that I do not know a body of men less moved by mercenary (I use not the word in an offensive sense) considerations. Witness the manner in which the metropolitan nurserymen have supported through evil report and good report the Royal Horticultural Society, and only this year I had the real pleasure of meeting in the far south-west of Scotland two of our leading rosarians, and although they took the chief prizes the money could not half have paid them for their expenses and loss of time.

The ground that I take will be seen at once when I say that I do not believe there is a flower show in the kingdom, general or special, that pays—that is, that the "gate money" as it is called—the contributions of the general public, not only do not pay the prize money and expenses, but in most cases would hardly even pay the latter. Let me, then, divide flower shows thus—I. Metropolitan; (a) those held by societies, (b) those by joint-stock companies, (c) special shows. II. Provincial.

I. (a) With regard to the great shows of the Royal Horticultural and Royal Botanic Societies we have had painful experience for some years. When successful—*i.e.*, when there is a large attendance of visitors, it is evident that horticulture is not the magnet. Music of the first quality, the attendance

of some member of the Royal Family, or some distinguished foreigner, will do more to attract the multitude than the finest exhibition that could be got together. The Tuesday meetings of the Royal Horticultural Society are really to the real lovers of flowers as interesting as anything can be, yet how very few avail themselves of them, only those who take a real loving interest in flowers caring to go there; and what I hope may prove to be its revived fortune is more owing to the countenance given to it during the past season by Her Gracious Majesty than to the fact that there is now a genuine horticultural Council. (b) The shows held at the Crystal Palace, Alexandra, and Aquarium are not in themselves paying concerns. The attractions of these favourite places of resort are numerous, and on flower-show days care is always taken to provide a good play in the theatre, fireworks in the evening, German gymnasts, or something else that may allure visitors. Then they must be always held in the season, and generally on a Saturday, in order to catch those fashionable people who care but little for flowers except in the case of a nosegay, but who dearly like to see and be seen. (c) The influence that horticulture has on the general public in alluring them to flower shows may be seen, I think, best by regarding special shows, not that these ever pay or can be expected to pay. A subscription list is first made, a schedule is formed in accordance with them, something is perhaps supplemented by the joint-stock company, but I very much question whether the increased attendance in any case is equal to the amount of prize money, without taking into consideration the expenses incurred. Let me just state one fact to support this. The Metropolitan Floral Society held its exhibition for three years at the Crystal Palace. It ceased to be held there because it did not pay. I went then to try and arrange, and the late Secretary showed me their book of attendances. We compared the attendance of the same days of the week in the week before and the week after, and found that it did not make a difference of a thousand!—that is of £50. At this show many flowers were represented, and I should be very much surprised to find that where only one flower is shown that a larger result is obtained. It may be asked, "Why are the shows held?" The statement to me of the manager of one of these places this year will be the best answer. He had offered to have the National Rose Society there, and said to me, "You know I shall lose money by it." "Why, then, do you have it?" "We must cater for the public, and unless we have variety we cannot do so. Some things pay and others don't, but we must have them." The National Rose Society never expected their show to pay—that is, as I have explained, they did not expect the gate money to cover expenses, prizes, &c. They trusted entirely to the interest taken in the Rose by the public at large. Their confidence was misplaced; only about a thousand tickets were taken, and probably many of these by the friends of subscribers. They had hoped to have taken at least three times as much as was taken at the first National Rose Show eighteen years ago; in fact, not more was taken than on that occasion. As to nurserymen foregoing the prize money, I think that is rather too much of a good thing to expect. They subscribe liberally, they go to great expense in coming up to town, and the least that they can expect is, I think, liberal prizes to compete for to recoup them in some way for the outlay.

II. *Provincial Shows*.—I call to mind many of these excellently managed and giving great impetus to floriculture, but I do not think one of them is ever expected to pay. First of all a subscription list is made up, to which all the gentry in the neighbourhood subscribe, and then generally something is added to it, always a band, sometimes fireworks, a poultry show, dogs or cats, or, as at York, acrobats and all kinds of fair amusements; and even then when a wet day comes the hat has to go round, a certain amount is expected on the show day, and if that fails it must be supplemented some way. Reference has been made to the big prize offered at Wisbech, as if that entailed destruction on the society that set the ball a-going. I believe that prize was suggested by a very distinguished rosarian. It was, I think, a mistake; but the failure of the Show (which was not exclusively a Rose show) arose not from this, but from purely local causes. I can speak with authority here, as I have judged there several times.

Your correspondent complains that nurserymen do not exhibit more at these provincial shows; my wonder is that they exhibit so much. The Rose show season lasts but little more than three weeks. During that time three great London exhibitions, others at Exeter, Nottingham, Oxford, Hereford, Maidstone, Helensburgh, N.B., Newton Stewart, N.B., Reigate,

Chipping Norton, &c., are held, and sometimes two or three on the same day in different parts of the kingdom. What, then, can nurserymen do? A Rose show is not like a poultry show, where you can send your birds and get them back again. Either the nurseryman himself or his most trusted men, who are at that time wanted at home, must accompany them; and unless he has any reasonable prospect of getting some money back he can hardly be expected on the hope of a few stray orders to go to all places at great inconvenience and expense.

I am, therefore, forced to the conclusion that flower shows do not and cannot pay; but at the same time I am convinced that the love for flowers is so great amongst us that they will still be held. We must, I think, abandon all notion about the scientific side of horticulture being a paying concern; we have no occasion to indulge in high talk, but seriously and lovingly do our best to promote the interests of the pursuit we love.—*D., Deal.*

CHOICE HARDY PERENNIALS.

"A CONSTANT SUBSCRIBER," who has plenty of common plants, asks for a list of some two dozen choice, distinct, herbaceous plants that would be in flower from May to September. By a lucky chance I am able to help him, and this is how it came about. Last August I went to see the garden of "PHILANTHOS," and besides the wonderful collection of Cowslips and Primroses about which he has told us so much that is new and instructive, I found many hardy flowers grouped in beds and dispersed about the gardens, enlivening many a quiet nook and corner, for they were mostly in full bloom, and as I soon saw were as choice and uncommon as they were beautiful, and so I am able to furnish a list upon which your correspondent may place implicit reliance as containing precisely what he wants. It is, moreover, worthy of general attention, few gardens possessing many of the plants I will now proceed to enumerate.

Aquilegia chrysantha.—This is the most charming Columbine I have seen. Its flowers are a delicate shade of yellow, are borne in clustering heads about 2 feet high, not at all dense or crowded, but in a somewhat loose yet elegant manner. It was seedling freely.

Potentilla purpurea lutea plena.—This had numerous flowers, double, and of a deep, rich, glowing crimson. It is one of many varieties of a neglected genus that are worthy of a prominent position in every garden. I have a list sent me from a reliable source, in which upwards of fifty varieties are enumerated, ranging in colour through various shades of crimson, yellow, and scarlet. They form dense bushy tufts, yielding a succession of brilliant flowers throughout summer. *P. Menziesii* was also very gay with single flowers of a rich crimson shade; and *P. William Rollinson* had brilliant clusters of double orange-coloured flowers, which told well among the crimson varieties.

Armeria cephalotes, better known perhaps as Great Thrift, had a gay and sprightly effect with its abundant large compact heads of rosy pink flowers borne on stems about 18 inches high, which spring out of dense cushions of leaves some 4 or 5 inches in length. This comes readily from seed, but some of the seedlings have flowers of a more delicate shade of pink than the original type.

Sedum spurium.—A fine species of this widespread genus with bold corymbs of bright crimson flowers and large green foliage. It was in full beauty, and appeared likely to continue so for some time. *S. kantschaticum* formed an appropriate companion for *spurium*, being similar in growth but having a profusion of deep rich yellow flowers.

Dictamnus Fraxinella had handsome spikes of pale pink flowers with dark green foliage, closely resembling that of a Dahlia or of some of the broad-lobed Ash trees. I find the following useful note of it in the "Cottage Gardeners' Dictionary":—"This is one of the oldest and best border plants of our cottage gardens. Instances are known where the *Fraxinella* has outlived father, son, and grandson in the same spot without increase, all attempts at multiplying it to give away a rooted slip to a newly married member of the family having failed; yet the *Fraxinella* may be increased from seeds. Sow as soon as they are ripe in the common soil of the border, and cover 1 inch deep; they will not sprout till the following April. If they are kept over the winter and sown in the following spring they will remain twelve months before they sprout, and not one in a hundred sprouts at all. When the seedlings are

two years old transplant them where they are to remain, and they will flower the third season. They prefer a deep rich border on a dry bottom, and all flower in June."

Carex riparia fol. aur. variegata is both elegant and sprightly in its long, slender, Sedge-like growth, and its variegated foliage was pleasantly conspicuous among the flowers around it.

Heimerocallis fulva fol. argenteo-variegata is another plant which impressed me favourably from the beauty of its variegated foliage, which was long, elegant, and flag-like, beautifully striped with white.

Geranium pratense flore-pleno had a profusion of charming purple flowers of fine form—just so many miniature rosettes, and the foliage, too, was much serrated and of elegant form. This is quite a gem, and once established it requires little subsequent care. It is a native of Scotland.

Anemone japonica Honorine Jobert.—This was in great beauty with its bold spikes of lovely white flowers. It is a general favourite so well known that I need not dilate upon its many merits here.

Anemone japonica is the original pink-flowered species from Japan, whence it was brought some thirty years ago. It is well known, but is not so generally grown as it deserves. It is true its flowers lack the elegance and precision of form so remarkable in the white variety, but they have a sprightly cheerful air pleasant to behold, and, moreover, continue in beauty late in autumn. It is readily increased by division. From a tuft or two which I procured from an old cottage garden two years ago I have now a stock of several dozens.

Bocconia juddoensis.—A remarkably bold and striking plant, which was full 7 feet high, with long loose spikes of white feathery flowers, having orange-coloured stems with a soft pearly-grey bloom overlaying the orange colour. The foliage was much lobed, serrated, and was broad and handsome.

Rumex vesicarius.—A curious and very pretty plant about a foot in height, with dense clusters of seed-pods covered with a beautiful pink veining like regular network.

Liatris spicata is another desirable plant which had lovely mauve-coloured flower spikes about a foot in height. It comes well from seed, and has been known in this country upwards of a century.

Spiraea palmata was in great beauty, is deservedly a general favourite, and I cannot do better than append Dr. Hooker's description of it:—"By far the handsomest species of the genus hitherto imported, and certainly one of the most beautiful hardy plants in cultivation. The deep purple red of the stems and branches, passing into the crimson purple of the glorious broad corymbs of flowers, contrasts most exquisitely with the foliage, which in autumn assumes beautiful tints of brown and golden yellow."

Aconitum bicolor variegatum was prettily variegated; it has compact spikes of curious hooded flowers, white with a deep blue margin.

Allium scorodoprassum was conspicuous among several others of this genus on account of its very dark crimson flower heads.

Iris foetidissima.—Although this was not growing among the plants of which I took notes, it is worthy of a place, for its elegant, flax-like, deep green foliage is always ornamental, and its pendant pods of bright scarlet berries just now in full beauty brighten a border wonderfully in winter, besides being useful for a variety of decorative purposes.

Acanthus latifolius was flourishing and elegant. It is a fine plant, which comes well from seed and is well worthy of a place.

Phlox decussata M. de la Deansaye had large bold heads of finely-formed deep crimson flowers. Triomphe du Parc du Neuilly was another fine variety with slender heads of handsome flowers of a deep rosy-salmon hue. M. Rafarin was a much brighter shade of salmon with bolder flower clusters. P. Grady with flowers of elegant form, white in colour with pink centres in large bold clusters, must conclude my selection.

There are two other classes of plants worthy of places in such a choice selection, and these are the herbaceous Pæonies and the Pyrethrums, both having numerous and beautiful varieties.—EDWARD LUCKHURST.

NOTES AND GLEANINGS.

We have received the schedule of the tenth quinquennial INTERNATIONAL EXHIBITION, which opens at Ghent on March 31st and closes April 7th, 1878. The programme is very com-

prehensive. It is divided into three sections—namely, plants, for which 274 classes are provided; arboriculture and the culture of market plants and fruit; also arts and industries, making a total of 321 classes. The prizes consist of objects of art, gold, silver-gilt, and silver medals. The gold medals alone number 117. We can only notice a few of the chief prizes. A gold medal is provided by the King for fifty Azalea indicas, the Queen being the donor of a similar prize for twelve Tree Ferns. A gold medal value five hundred francs is provided by the federation of the Belgian horticultural societies for forty Palms, and an object of art of the same value is offered by the President of the Society, the Comte de Kerchove, for seventy-five plants in and out of flower, the contribution of the Comtesse de Kerchove being an object of art value three hundred francs for 150 Hyacinths. Gold medals of the value of 250 francs are offered by the members of the Council of Administration to nurserymen and amateurs for twenty Orchids, also for thirty Dracenas and fifty Rhododendrons. We note also that the English Van Houtte Memorial Committee provide two prizes for Belgian exhibitors of six stove and greenhouse plants of distinct genera, in the form of objects of art of the respective value of 250 and 125 francs. Mr. William Bull also offers three silver cups value fifteen guineas, ten guineas, and six guineas to Belgian exhibitors of twelve distinct species or varieties of plants introduced into commerce by Mr. Bull since 1873. We trust the promoters of this great Exhibition will be well supported at home and abroad, and that the response of horticulturists will be commensurate with the efforts made to ensure their countenance and co-operation.

—OUR readers will have noticed in our advertising columns an announcement of a NEW PEAS Criterion, which is being introduced by Messrs. Veitch & Sons of Chelsea. It is always interesting to know the origin of names. A correspondent informs us how the name was given to this new Pea, which, when known as well as it undoubtedly will be in a year or two's time, will be deservedly familiar to every gardener. The late Mr. John Standish devoted much attention during several of the closing years of his life to the raising of improved varieties of Peas. His principal object was to produce hardy early Marrowfats of fine quality. It was his custom annually to gather his horticultural friends around his hospitable table at Ascot, when Peas were at the best, to taste the new seedlings. On the occasion of the last of these gatherings a gentleman connected with Messrs. Spiers & Pond's "Criterion," in Piccadilly was present. The Peas submitted for critical opinion having been tasted at dinner and warmly approved of, Mr. Standish invited his guests to go into the grounds and see the Peas growing. Pointing out some rows of the kind which was considered the very best of all, he was asked if he had named it. "No," said he, "but I want a very good name for it, as I consider it the best Pea in cultivation;" whereupon one of the company (our correspondent) suggested the name "Criterion," which, being thought very appropriate, was at once adopted. It is described as an early Ne Plus Ultra, a description it deserves, and which says volumes in its favour. Having seen the Pea growing side by side with many other kinds, we can say it is very hardy and of excellent quality.

—THE GERANIUM HOUSE in Mr. Cannell's nursery at Swanley is in great beauty, and affords evidence of the value of the newer varieties of zonal Geraniums for winter decoration. Some of the varieties are finer in winter than in summer; David Thomson, for instance, which is now very striking. Others which are highly effective are Seraph, Alonzo, Lizzie Brooks, Miss Gladstone, G. Morlet, Fairest of the Fair, Circulator, Dr. J. Denny, Mrs. Lancaster, Livingstone, Jean d'Arc, Mrs. Leavers, Mrs. Wright, Corsair, Jealousy, Louisa, Gertrude, Mr. Chandler, Imogene, The Shah, and Ivanhoe.

—THE first prosecution under the Adulteration of Seeds Act, 1869, came before the Lord Mayor at the Mansion House on the 26th inst., when Mr. Thomas Strangeways, a seed merchant in Mile End, was fined £5 for the offence of killing seed, and £5 for that of selling the killed seed, and £5 5s. costs, or £15 5s. in all. Mr. Alexander Francis stated that he purchased sufficient of killed seed which if mixed in the proportion of half-and-half would sow about 1700 acres. Mr. Charles Sharp of Sleaford deposed that he, with Mr. Burnell, promoted the "Adulteration of Seeds Act," and he employed the last witness to make the purchases in question.

—WE have letters bearing testimony to the excellence of VEITCH'S AUTUMN GIANT CAULIFLOWER. Mr. Wilson, Claydon House, Winslow, states that he had 150 plants, and the heads

averaged 2 feet 6 inches in circumference. He describes it as a splendid variety; and Mr. Iddenden, market gardener, Ashford, states that he has cut a head 44 inches in circumference, yet very close and compact. Some of the finest heads we have seen were grown this year by Mr. Jones at Bentley Priory. They are remarkable examples of what must justly be described as one of the most valuable of autumn vegetables.

SINCE Mr. Baring's garden at Coombe Cottage was described on page 34 some important alterations have been made, which have added considerably to the completeness and usefulness of the glass structures. Some commodious, excellently arranged, and well-constructed vineries and pineries have been erected, also a Fig house, which are already occupied and doing good work. The houses have been erected and heated by Henry Ormson, Stanley Bridge, Chelsea. The heating is efficiently and economically done by flued saddle boilers, and all the pipes are on the same level; little or no difference is found in the heat of the flow and return pipes by this arrangement. The several houses are also well occupied. Young Vines are extremely promising; Orchids are numerous and in thriving condition, as also are ornamental-foliaged table plants and flowering plants. We never saw *Pleione maculata* in such fine condition, one pot containing about sixty charming flowers. *Odontoglossum cirrhosum* is showing strongly; the brilliant *Sophranitis grandiflora* is just expanding, and will continue in beauty for three months; and *Cattleya Dayana* and *Odontoglossum Roezlii* are very fine. Cut flowers, which are in great demand, are chiefly afforded by *Gardenias*, *Roman Hyacinths*, *Ixoras*, *Euphorbias*, *Eranthemums*, *Azaleas*, *Camellias*, *Scutellararias*, *Centropogons*, *Heliotropes*, and *Mignonette*. *Amaryllis sulcata*, Mr. Baker's fine variety, is also extremely effective.

AT the TAUNTON ROOT SHOW held on the 24th inst. Messrs. Kelway & Son's five-guinea silver cup offered for twenty roots of their Magnum Bonum Mangold was awarded to Mr. Carter of Huntspill, near Bridgewater, and their five-guinea silver cup for twenty roots of Kelway's Mammoth Swede was awarded to Mr. James Mead of Yarlinton, near Wincanton.

A FEW remarkable ORCHIDS are now flowering in Messrs. Veitch's fine collection at Chelsea. Foremost to notice is *Cattleya exoniensis*, Mr. Dominy's greatest triumph and brilliant memorial. The plant has thirteen expanded flowers and nine buds; and such flowers! one scarcely knows which to admire most, the soft delicacy or the intense richness of colouring which are combined in this fine variety. The sepals and petals are silvery blue, the lip bluish violet deepening to purple and margined with white, and the throat is rich orange, the margins of every part of the flower being beautifully fringed. Too much cannot be said in praise of this magnificent Orchid, which is worth a long journey to see. Its parentage is *Lælia purpurata* and the Sion House variety of *Cattleya Mossiae*. Near it is *Cattleya fausta*, the first seedling Orchid raised by Mr. Seden; the prevailing colour is reddish mauve, which has a rich effect by gaslight. It is the result of a cross between *C. exoniensis* and *C. Loddigesii*. A new *Cypripedium* of great promise is flowering. It is the result of a cross between *C. Dominii* and *C. Schlumieri*. In colour it resembles *C. Sedeni*, but the flower is much finer, the throat more spotted, and has, what *Sedeni* has not, long twisted tails. It has bright green arching foliage, and is of stately habit. Yet another new plant merits notice—namely, *Calanthe Sedeni*. All who know *C. Veitchii* know how valuable it is. The new variety is between that and *C. vestita*. It is larger than *Veitchii*, and is very similar in colour, but in addition has the white sepals and bold chocolate throat blotch of *vestita*. This fine new *Calanthe* is sure to become popular. *Chrysanthemums* are still gay; they have been grown in a more natural manner than during previous years, and the ordinary character of the varieties is the better appreciated.

A NORTHAMPTONSHIRE correspondent in writing to us on the effects of the late GREAT GALE, says—"My whole estate was strewn with fallen trees. They came down like nine-pins. A small sprinkling, too, of barns and cottages were considerably dispersed."

WE have, writes "OBSERVER," some very fine specimens of different kinds of HOLLIES, and the contrast between last season and this is most apparent. The difference between no berries and the trees being red over is very striking. Specimens of Hollies variegated and self-coloured, 30 and 40 feet in height and more in circumference, clothed with their shining foliage and their coral-like berries, are very attractive objects

during the dark days of winter, and will no doubt afford food for fieldfares, missel thrushes, and other of the feathered tribe.

THE annual ROOT SHOW of Messrs. Edward Webb and Sons was held at Wordsley, near Stourbridge, on the 20th inst., and was in every way successful. There were 1308 entries against 1272 last year, and £300 was offered by Messrs. Webb in cups and other prizes. The whole of these prizes are given for roots grown from their seed. Among the more prominent exhibitors were Her Majesty the Queen, the Duke of Sutherland, the Duke of Portland, the Earl of Craven, the Earl of Denbigh, the Earl of Dartmouth, the Earl of Stamford and Warrington, the Earl of Warwick, Lord Lovatt, Lord Hampton, Lord Northwick, Lord Moreton, Lord Leigh, Lady Ward, Viscount Hill, Sir George Chetwode, Bart., Sir H. S. Stanhope, Bart., Col. Dyott; Messrs. C. Combe, W. D. Foster, T. H. Farrer, W. L. Beale, Joseph Beach, Samuel Robinson, W. T. Carrington, Joseph Palley, and T. Jowitt. The principal feature of the Exhibition was the specimens of Webb's Imperial Swede, in which class there were 496 entries. The heaviest single roots shown were—Imperial Swede, 23½ lbs.; Yellow Globe, 36½ lbs.; Long Red Mangold, 44 lbs. There was a large attendance of visitors.

IN the reports of the chief London flower shows "Mr. Roberts, gardener to W. Terry, Esq., Peterborough House, Fulham," frequently recurs in the prize list. We recently had a "bull's eye" view of MR. TERRY'S GARDEN, and were much pleased with the appearance of the houses. The collection of medicinal and official plants is extremely interesting, and Orchids are very numerous, and are steadily improving in health under Mr. Roberts's care. Stove and greenhouse plants are also well managed, and forcing is ably conducted, Cucumbers and French Beans being provided "all the year round." It is pleasing to notice, too, that old border flowers are cherished; but to appreciate these a daylight visit is necessary. This we hope to have on a future occasion, when more particular note can be taken of many things that are noteworthy in this well-appointed and excellently managed garden. Amongst the plants that cannot be grown are Violets, the London fogs being fatal, or nearly so, to these esteemed flowers; neither in pots nor borders can they be made to flourish during the winter at Peterborough House.

THE most highly-flavoured MADRESFIELD COURT GRAPES that we have tasted were grown by Mr. Burnett at Deepdene. They are grown on the Black Hamburg stock, on which Mr. Burnett states they never crack with him. They are of splendid quality. We should be glad to hear of the experience of others who have grown Madresfield on Black Hamburg roots. Mr. Burnett finds, also, that Royal Muscadine is an excellent stock for Mrs. Pince's Black Muscat. He has forty bunches on two rods, which are very fine and are better coloured than we often see this Grape.

DURING the October of 1876 rather more than 237,000 cwt. of Potatoes were imported, but in the same month of the present year nearly 1,100,000 cwt. have been imported.

THE mild autumn weather, writes a Yorkshire gardener, appears to put things out of season. We have here a fine old plant of SCORPION SENNA (*Coronilla Emerus*) nearly a mass of bloom. Its beautiful yellow-tinged-with-red flowers in the sunshine give it a charming effect. It began flowering in early summer and continued in beauty for a length of time, and now with renewed vigour it is making an effort to cheer us on the eve of winter. He urges the more extensive cultivation of this plant for indoor decoration. The plants succeed in any ordinary soil in well-drained pots supplied with water as they require it. When not wanted they can be plunged in the reserve ground till wanted.

ORANGES are being imported from the Brazils. This is the first year, says the *Mercantile Gazette*, in which any important quantity has been brought to this country, great difficulty having been previously experienced in getting the fruit in sound condition. This has, however, to some extent been overcome by care in gathering, packing, &c. The quality of this Orange is said to be extremely fine, being ripe and sweet, which no European Oranges are at the present period of the year.

OWING to frequent showers and a prolonged period of mild weather, WINTER GREEN CROPS have recently grown with great rapidity. Broccolis are luxuriant and succulent, and consequently in considerable danger should frost come sud-

denly and severely. Spinach, autumn-sown Cauliflowers, and Lettuces are also growing fully too quickly. A check with the spade—partially lifting the roots of such crops, is often useful in arresting their luxuriance, and thus rendering them somewhat better able to resist the first onslaught of winter. Weeds grow as fast as vegetable crops, and it is a moot point whether they or slugs are just now the more troublesome. Lime, soot, and guano are real gardeners' friends—the molluscs detest the mixture, and the crops enjoy it.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

HARDY FRUIT GARDEN.

To the ordinary observer there is much sameness in the appearance of the fruit garden during winter; to the uneducated eye the buds, branches, and outlines of the trees present the same monotonous effect; not so to the ardent fruit cultivator. As he walks round his trees he can note the changing buds swelling during mild weather, those that are plump and roundish showing the quantity of blossoms that may be expected on the trees. Then there are certain small details of the work that require to be seen to. A stout sharp knife is useful to cut out superfluous wood. The eggs of *Bombyx neustria* (lackey moth) may be found glued to the small branches in clusters. The caterpillars of the goat moth may also be traced by their borings, like wet sawdust dropping out of a puncture in the trees. A good plan to destroy them is to crush them by the insertion of a pliable wire. We have seen both Elm and Apple trees destroyed by this pest to the fruit cultivator. They will bore into the hardest wood, and if not destroyed in time they work in a zigzag direction to the centre of the tree, and a wire will not follow them into such distant retreats.

During the present mild weather we are busy looking over all the fruit trees and pruning them. After this is done the ground underneath will be mulched with manure. Gooseberry and Currant trees will also be pruned as soon as possible. Many readers of the Journal who have such trees and bushes are probably ignorant of the methods to be employed in pruning, or the way it should be performed. It is very difficult to describe this, but the main idea of the cultivator is to thin out the wood freely in the centre of the Gooseberry and Currant bushes, so that the sun may be able to act beneficially on the leaves and fruit. Red and White Currant bushes do well when the young wood is cut closely back to the main stem, except the leading shoot, which may be left about 6 inches long, more or less as it is intended to increase the size of the bushes. A large proportion of the young wood may also be cut from the Gooseberry bushes. Those growths that may be allowed to remain have merely the points taken off them, but they must be well thinned out, else the produce will be inferior. It cannot be too widely known that good fruit cannot be obtained from trees where the wood is thickly placed.

Many persons cannot get out of the custom of inserting Strawberry runners thickly in beds and planting them out after they have formed a considerable quantity of roots. Those who have done so may now plant out while the weather continues mild. The plants will continue to grow except during frosty weather.

Plantations of Raspberries may also be made now. A damp shady part of the garden answers well for them, but to have plenty of good fruit the ground must be deeply trenched, working in plenty of rich manure. After the plants have been put out mulch round the roots with drish frame manure. All newly-planted trees should be mulched. Instructions have been previously given as to the best methods of training the wood. Old plantations should be heavily manured. The manure is best wheeled on to the ground in frosty weather. It will not do to dig the ground until it is thawed.

PEACH HOUSES.

It is now time to start the earliest house, and if previous instructions have been followed out all the woodwork and glass will have been washed clean, and the walls limewashed. The branches also should be washed with soapy water, especially if thrips, red spider, or scale should be in the house. The young wood should be carefully washed so that the fruit buds may not be injured during the operation; the old wood that is not furnished with buds should be dressed with the mixture recommended for Vines. All the wood must also be in its proper place before forcing commences, and it must be tied to the trellises in such a manner that the bearing wood is distributed evenly all over the space devoted to it. The borders should be well watered to start with, but the temperature must not be too high at first; if the weather is cold with frosts at night, 40° to 45° ought not to be exceeded. Should the weather be mild a minimum of 55° may be maintained without any artificial heat. The trees may be gently dewed overhead on the mornings of fine days, but it is undesirable to have the atmosphere of the house loaded with moisture.

CUCUMBERS.

The critical period for these is now approaching, but if the appliances at command are adequate for the occasion, and if the plants have been managed as previously directed, there will be no difficulty in satisfying any reasonable demands. Our own plants are in excellent health, and are now beginning to bear fruit; the growths are not too close to each other, so that the leaves are exposed to all the light possible. The night temperature ranges about 65°, less or more according to weather, but we do not like the temperature to fall below 60°. Every day, except during keen frost winds, the lights at the top of the house have been moved down an inch or two to cause a circulation of air. This may be done about 10 a.m., and the house be closed at 2 p.m. It is not desirable to have a very moist atmosphere, but this must be regulated to some extent by the heat that it is necessary to maintain in the hot-water pipes. Thrips have appeared on the leaves, but successive fumigations with tobacco smoke destroy them.

FIGS IN POTS.

We have not done well with these during the past season, the reason being that the plants were under Vines and standing at a considerable distance from the glass. We have always succeeded best with Figs when the pots could have a gentle bottom heat and be grown in span or hip-roofed structures, the plants close to the glass, and nothing to shade them from the sun. We have just turned the plants out of their pots, and repotted them in rich heavy loam with a fifth part of decayed manure; as was to be expected from plants that had made weak growth there was little root-action. We will try and get the plants into a house where they can grow and fruit freely next season. It is evidently not worth the trouble to try to grow them under Vines, better throw the plants away than have them languish out a miserable existence.

GREENHOUSE AND CONSERVATORY.

One of the most useful plants for late autumn or winter flowering is the *Statice profusa*. We have plants of it now covered with flower spikes, some with them fully expanded and others in various stages of development. A large plant in flower now will improve until midsummer. The white corolla in the centre of the flower will drop off, but the blue portion of the flower will remain in the state that *Everlasting Flowers* are when gathered. It is subject to mildew, but dusting the leaves with sulphur destroys this parasite. The flowers mentioned by "VISITOR" in the notes of Mr. C. Turner's nurseries, Slough, should be in every collection—viz., *Browallia elata* and *Salvia splendens*. They are quite as easily grown as zonal *Pelargoniums*. The plants may be placed out of doors during summer and autumn, removing them into the greenhouse in September or as soon as there is danger of injury from frost. Indian *Azaleas* are now at rest, and the old leaves are dropping off. These should be removed out of the way; perhaps it is best to burn them, as this beautiful flower is too often infested with thrips, a lively little insect that cannot easily be destroyed when it has been allowed to increase rapidly. There is no better plan than to continue to fumigate with tobacco smoke until they are destroyed. We have taken in the earliest pots of Tulips, Hyacinths, and *Polyanthus Narcissus*. The pots are well filled with roots, and they have been placed on a shelf near the glass, where they have just a little artificial heat, but plenty of fresh air is admitted when the weather is fine.

Cyclamens which have been until now in a cold pit have been removed to a warmer place near the glass. The flowers, which are showing in hundreds, will thereby be hastened, and we shall be glad of them in a few weeks. This is now a generally cultivated and most useful plant, and the great variety in colour and quality of the flowers have been much increased during the last few years. It is necessary to be careful in watering the plants at this season. The water should be poured in very gently near the rim of the pot. If it is dashed into the centre of the plant probably many of the flower stalks will decay.

Tree or Perpetual-flowering *Carnations* are now very useful for arranging amongst *Azaleas* or other hardwooded plants. When arranged in such a way that the *Carnation* flowers slightly overtop the plants named they have a charming effect. These are everybody's flowers, they are so easily grown. Out-of-doors culture suits them best until it is too cold, when they are brought indoors, and by that time the flower buds are formed, and the dry air of the greenhouse causes the blooms to open freely. A variety nearly white named *Empress of Germany* is a beautiful flower. The choicest *Orchids* cannot be placed before it. What a contrast to it, too, is *Scarlet Defiance*; the brilliance of this flower is quite dazzling. Then there is the freest-flowering variety we have with flesh-coloured flowers—*Miss Joliffe*. *La Belle* is a very good pure white flower, and we have in *King of the Belgians* an excellent pink-coloured sort; the edges are beautifully fringed, which in the estimation of some adds to its beauty. The flowers will open with additional freedom if the plants are placed in a house with a drish atmosphere and a temperature of 50° or 55°.—J. DOUGLAS.

TRADE CATALOGUES RECEIVED.

Dick Radclyffe & Co., 129, High Holborn, London.—*Catalogues of Vegetable, Flower, and Garden Seeds, Dutch Flower Roots, Trees, &c.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

APPLE-TREE BARK CANKERED (*A. B. G.*).—The roots have descended into an ungenial subsoil; if so, they should be cut through and manure spread on the surface to induce rooting in that.

RECTOR'S WIDOW (*Old Subscriber*).—She can take away all the potted plants if first introduced by her husband, and the incoming rector ought not to object to her taking cuttings of the herbaceous plants.

CELERY WORM-EATEN (*A. A. M.*).—Apply successive waterings of fresh lime water.

TRANSPLANTING ROSES (*Idem*).—You may transplant your Briars budded last August with perfect safety now.

ROSE MOSS DE MEAUX (*Idem*).—We much fear this charming old favourite is lost, as none of the "Rose" nurserymen name it in their catalogues now.

CETERACH OFFICINARUM (*Idem*).—This Fern is somewhat difficult to establish in new quarters. Fill a pot half full of drainage and the remainder with a mixture of one-third loam and two-thirds of broken bricks, make a little mound in the centre, upon which place your plant, water sparingly and carefully for a time, keeping it in a cool frame or under a bell-glass in the coolest part of your conservatory.

VINES FOR A COOL VINERY (*Rass*).—Three of Frankenthal and one Black Alicante; and as you require four white you cannot do better than plant two Buckland Sweetwater, one Early White Malvasia, and one Royal Muscadine.

INSECTS ON ROSES (*F. W. T.*).—Immerse the infested roses in pots in a strong decoction of Fowler's insecticide, afterwards washing them with pure water. If they are too large for immersion lay them on their sides and syringe them thoroughly with the solution.

WINTERING GLOXINIAS (*Hortus*).—Place the pots on a shelf in a vinery at rest or in any place where frost is excluded, and do not let the soil become dust-dry, but give a little water twice or thrice during winter, shake them out, and repot in spring. Notes on Clematises will shortly be published.

ILLUSTRATED CATALOGUE (*Mrs. H. B.*).—The leaf you sent is from Messrs. Dick Radclyffe & Co.'s Catalogue. There are many other illustrations in it besides those you have sent.

PORTABLE ARNOTT'S STOVES.—We have many inquiries for these, and about their cost, fuel consumed, &c. Makers would benefit by advertising these particulars.

ROSE CUTTINGS (*A. C.*).—November is a good month in which to insert the cuttings out of doors of those hardy varieties that are usually propagated in that way. We presume you intend the Briar cuttings to be inserted on which to bud Roses for bedding. We do not think that a good plan. It is best to plant Roses on their own roots for bedding.

VETCH MEMORIAL PRIZES (*Belfast*).—When arrangements are made as to who will be eligible to compete they will be duly advertised.

ROSE DEVONIENSIS NOT GROWING (*Idem*).—It is very liable to be attacked by mildew, and this will account for the reddish-brown spots on the wood and leaves. This parasite should be destroyed on its first appearance. If you cut *Maréchal Niel* as closely as you propose it will not produce nearly so many flowers. If you desire a large quantity of flowers you must not cut the young wood back severely, but then the plant will shade the greenhouse too much. You can only get rid of the maggot boring the leaves of your *Clematis* by bruising them between the finger and thumb.

HEATING SMALL PIT (*A Subscriber*).—One brick flue run along the pit within a foot of the front wall will give sufficient heat.

HALF-HARDY AMARYLLIS IN POTS (*A. J.*).—When grown in pots these plants do die down during their period of rest. They should be kept rather dry at the roots during that time.

SHORT-STALKED CELERY (*F. I. Radclyffe*).—The length of stalk is determined by the kind and the culture. We should manure more liberally and water abundantly during dry weather, and give liquid manure twice a week. We have seen the plants drawn up a good length by 4-inch drain tiles enclosing them, and is not a bad plan in wet soil, the space inside the tiles being filled with sawdust around the Celery, the tiles being raised as occasion may require when earthing. The Celery being good though short indicates that more liberal treatment only is required.

CAMELLIAS INFESTED WITH THRIPS (*Cold*).—The leaves of the Camellia and the narrow-pointed leaves—certainly not those of *Stephanotis*, being more like *Garcinia intermedia*—are infested with thrips, which may be destroyed by fumigation with tobacco, the atmosphere being very much too dry to cause so serious an infection. The smaller leaves have on the under side next the midrib some brown scale, which should be cleaned with a sponge and a solution of soft soap, 4 ozs. to the gallon of water. Both the plants would be the better of a thorough cleaning by sponging the soap solution on both surfaces of the leaves. There is no mealy bug or traces thereof. After sponging syringe the plants with clear water.

PACKING FRUIT, FLOWERS, AND VEGETABLES (*Young Gardener*).—For sending by rail fruit is best packed in boxes made of half to three-quarter-inch deal, and so deep as to hold one layer of each kind of fruit only, with sufficient space for a little stuffing below and over the fruit. Grapes, Peaches, Nectarines, Plums, Pears, and choice Apples are first wrapped in tissue paper, and are then placed in the boxes with a little bran beneath them. The box is filled closely one tier deep and more stuffing added so as to fill up the interstices and the box, the chief thing being to have the whole compact so as to prevent the fruit moving. The lids are secured with screws. Great care is necessary in handling Peaches, which we wrap in

cotton wool or wadding in addition to the tissue paper. Strawberries are packed one layer deep in their own leaves, each fruit in a leaf. Preserving or culinary fruits are best packed in small wicker baskets. Flowers are best packed in tin boxes, which may be 3 or 4 inches deep, or have trays so as to accommodate three or more tiers of flowers. A little damp moss is placed at the bottom; the stem of the flower is wrapped around with a little wadding immersed in water and the water squeezed out as from a sponge, and the flower covered with tissue paper, and in the case of Camellias with wadding; they are then placed rather tightly in the box in layers, the chief point being to have them tight without crushing; some cotton wool is placed over them, and a tray or the lid is put in or on. Note, the wool must not touch the flowers, but be kept from them by tissue paper, as it sticks to some flowers and absorbs moisture from those with smooth petals. The flowers should be cut in the morning, and ought to be dry when packed. Vegetables travel well in hampers, it not being desirable to have them too large. Ours vary in size from one to two bushels; one midway of those we find most serviceable. Cooking Apples and stewing Pears travel well in hampers with hay or straw around the sides, packed in layers with straw or hay between each.

MALFORMED PEAR (*Dalton*).—We have seen similar deformities. The small Pear issuing from the eye of the larger Pear arose from an extension of the growing axis called a profliferous growth.

ROSE CULTURE IN CHALK SOIL (*A. S. M.*).—Drain the soil thoroughly, dress it heavily with rich farmyard manure, which take especial care to blend thoroughly with the soil, and you will succeed. We infer that you allude to a soil resting on chalk, such as is found upon the chalk hills of Kent. You need have no hesitation in planting Roses upon Briars in soil where, as you say, Hops and fruit trees appear to thrive splendidly. The common Briar abounds in hedgerows upon the chalk hills, and some years ago we remember budding many hundreds of such, which were very robust, and formed large bushy heads quickly.

REMOVING SHRUBS AND TREES (*T. S. R.*).—If your *Cupressus Lawsoniana* was "well prepared last spring" for removal you may safely transplant it now. Decayed leaf soil is very suitable for placing round the roots. See that the roots do not become dried during the process of removal, and secure the specimen from injury by high winds. The Mulberry may be moved now, placing leaf soil round the roots as you propose, but it would be much safer to prepare it now and remove it next autumn.

BRITISH SHOW (*Inquirer*).—Special certificates were awarded to Mr. Stephenson, gardener to E. Peek, Esq., Roby House, Sydenham Hill, for Black Hamburgh and Black Alicante Grapes.

GRAFTING VINES (*J. W. Lever*).—The Sheffield correspondent has left his residence, and we cannot obtain his address.

CUTTING HOLLY HEDGES.—"An Observer" writes that he finds the spring the best season for the operation, and we consider that that season is to be preferred.

DRAINING PEAT SOILS (*T. V. M.*).—The best directions we know are in the second volume of the Royal Agricultural Society's Transactions.

GLAZING WITHOUT PUTTY.—"E. W. R." and others wish to know if any of our readers have adopted this mode of glazing and have found it successful.

MELONS FOR EARLY FRUITING (*Novice*).—The best green-flesh for your purpose is Gilbert's Improved Victory of Bath, and the best scarlet-flesh Turner's Scarlet Gem. You must sow the seeds early in January and maintain a temperature of 65°; the fruit will if other circumstances are favourable ripen in the end of May. What are usually called "inch bones" are better for a Vine border than dissolved bones, being much more lasting.

SELECT LARGE-FLOWERED AND ANEMONE CHRYSANTHEMUMS (*G. C.*).—*Large-flowered*.—Aurea Multiflora, Barbarea, Empress of India, Eve, General Bainbrigge, Golden Beverley, Hero of Stoke Newington, Jardin des Plantes, Lady Hardinge, Her Majesty, Mrs. Geo. Bunde, George Glenn, Prince Alfred, Prince of Wales, Princess of Wales, Venus, Mrs. Dixon, Princess of Teck, and White Venus. *Anemone-flowered*.—Acquisition, Georges Sande, Empress, Prince of Anemones, Glück, Queen Margaret, Mrs. Pethers, Lady Margaret, Princess Louise, Sunflower, King of Anemones, Fleur de Marie, and Louis Bonamy.

PHYLOXERA ON VINE (*C.*).—The root has all the appearance of having been attacked by this insect. There are traces of the insect, but that is all. Did you not observe peculiar excrescences upon the under sides of the leaves as well?

PRUNING VINE (*A New Subscriber*).—You do not say what sort of wood the Vine has made; but you would do well to leave the young wood in places where there is space for lateral development, and when lateral growths are formed cut back to a good eye. Read "Seasonable Notes on Vines" on page 412. Look out also for directions in "Doings of the Last Week."

NAMES OF FRUITS (*L. R. Lucas*).—1, Aston Town; 2, Swan's Egg. (*J. M.*)—Martin Sec. (*R. P. J.*).—Name not known. (*Col. E. T. C.*).—Trumpington. (*S. W.*).—Eldon Pippin. (*Keymer*).—1, Northern Spy; 2, Beauty of Kent; 3, not known; 4, Claygate Pearmain; 5, Hollandbury; 6, Kingston Black. (*J. Woodliffe*).—1, Pinner Seedling; 2, Fomme de Neige. The Pear is *Ne Plus Meuris*. (*W. Taylor*).—1, Ashmead's Kernel; 2, Sturmer Pippin; 3, Golden Russet; 4, not known. (*W. P. B.*).—1, Beurre Diel; 2, Nouveau Poiteau. The Apple is Court of Wick.

NAMES OF PLANTS (*M. Ambleside*).—The specimen imperfect. It seems to be *Linum trigynum*, Three-styled Flax. (*Stirling*).—We have not seen the specimen to which you refer. Send again when the plant is in flower.

POULTRY, BEE, AND PIGEON CHRONICLE.

RABBIT TROUGHS.

The question of Rabbit troughs occupies a far more important place in the economy of Rabbit-keeping than is generally assigned to it. During the last few years important improvements have been made in the construction of hutchers and other matters of detail, but in a few noteworthy exceptions the ordinary Rabbit trough has scarcely undergone the slightest alteration. It is strange that so little interest should be taken in such a subject, seeing that as a rule Rabbits waste rather more food than they eat; but this loss could easily be avoided by the

adoption of a suitable trough. Then, again, a Rabbit frequently refuses its food, and loses its flesh simply because the food, which may be of the best quality, is improperly served. The time has passed when it was considered that anything would do for a Rabbit, and fanciers have learned or are beginning to learn that economy in small things is a necessary adjunct to success. Below we give several specimens of Rabbit troughs, some original, and some improvements of the kinds now extant.

The commonest troughs are square or oblong boxes without any protection, and saucers or flower-dishes. The former are soon destroyed and made obnoxious by the Rabbit squatting in them. The latter are much worse. All the inhabitants of the hutch, young or old, seem to consider them lawful places for reposing in, and, moreover, to look upon them as improvements in the sanitary line. It is not long before any food in them is converted into filth, and if not remedied the Rabbit will soon lose health.

The best and simplest kind of trough is perhaps that made of zinc and wood, the former forming the trough itself, and the latter the side pieces. The zinc should be bent into a semi-circle, the half tunnel thus formed to be 9 inches long and $3\frac{1}{2}$ inches across the top. The side pieces should be made square so as to keep the trough from falling over. There will now be a feeding dish capable of holding enough food for half a day for a doe and large litter of young. If left as made it would not be economical, as the food would soon be scratched out and the Rabbits get into the trough. To remedy this, bore four holes in the zinc opposite one another, and lace them with copper wire of a good thickness. If laced across one another so as to form a kind of latticework it will be best, but care must be taken to leave apertures large enough for the nose of a large Rabbit to go through, but too small to allow a young Rabbit to crawl between. The wires should be laced at each passing for extra strength. To affix the zinc to the wood it is best to cut the former longer than necessary, and turn half an inch over at each end, which can be nailed to the wood with tacks. A good carpenter could make it watertight, but an amateur hardly could, and it should hence be used for dry food only. A trough of this description will not cost more than a common one, and it will last a lifetime. As it is of a really lasting kind it will pay to spend a few extra pence in purchasing a piece of really good wood for the sides, as deal or pine is very apt to be split or weakened in the making. To keep it from being overturned bore a hole in the side of the hutch and insert a piece of wire in the form of a hook. This can be affixed to one or more of the troughs.

Another kind of trough is a simple wooden box made the necessary size and covered with wires in a similar manner to that described above, or wires of a stronger nature may be affixed longitudinally about 2 inches apart, so that if the trough were 4 inches across a wire should be fixed an inch from each side. The cost of making a trough of this description will be but the smallest trifle under the one first described, and it will be quite as much trouble. It will not, however, last so long, as it is more difficult to cleanse it, and be as careful as possible it will get tainted by use. This should be fastened to the side of the hutch in the same way as already described.

For a watertight trough a sheet of zinc should be obtained and bent in the proper shape, the sides and joints being hammered too tightly to allow any leakage.

These troughs will be found to answer every purpose for does with litter or batches of young Rabbits, but they would be unnecessarily large and cumbersome for a single buck Rabbit. For him the easiest and perhaps the most serviceable trough is made of zinc in a circular shape, the edges being all turned over a thin iron bar for the sake of strength. The trough should be fixed to the bottom of the hutch by a couple of strong nails. To prevent the food being scratched out make the sides 3 inches high, and let them slightly converge towards the bottom. These troughs will be found cheap and effective.—GETA.

THE BIRMINGHAM CATTLE AND POULTRY SHOW.—A considerable portion of the exhibits for this, the twenty-ninth annual Show, are now in Bingley Hall, and ready for the inspection of the Judges on Saturday, December 1st. The entries of roots and potatoes show a large increase. The applications for space from implement manufacturers are larger than ever before known, and many have been declined; others cut down to very small proportions. The poultry number 2700 pens, and the Council have found it necessary to hire 500 additional pens for their reception. Among the exhibitors are Her Majesty the Queen, H.R.H. the Prince of Wales, the Dukes of Buckingham, Marlborough, Portland, Northumberland, and Sutherland; the Countess of Chesterfield, Countess of Dartmouth, Earl of Lonsdale, Earl of Crawford and Balcarres, Earl of Ellesmere, Lord Falmouth, Lord Chesham, Earl of Galloway, Earl of Harrington, Lord Leigh, Lord Lovat, Earl of Powis, Lord Tredegar, Lord Walsingham, Sir Watkin Wynn, Mr. McCombie, the Corporation of Birmingham, &c. As usual, the judging will take place on Saturday, when the charge for admission is 10s., life members

only having free passes; on Monday the charge is 5s., subscribers' tickets being available. The others are 1s. days, a concession being made on the last two evenings in favour of the working classes, by reducing the payment on entrance to 6d.

NOTES ON CANARIES.

I HAVE often been asked to recommend the sort of Canary to make the best cage songster. One's idea at once inclines towards the German songster, but unfortunately such is the brief duration of life that no dependance can be placed upon any purchased bird passing through the moulting sickness and again breaking forth into song equal to that when first obtained. Like the Nightingale, appearances do not favour the German bird, which possesses only a moderate garb compared with many of its congeners. The disappointment, no doubt, is great to those who invest their money in purchasing a really first-rate German songster, to find that after a brief season the bird becomes silent. To please the ear and the eye what can suffice better than one of our charming-bred Norwich birds tutored in its youth under a German schoolmaster purchased in the spring of the year? Norwich songsters possess both power and volubility of voice, which when cultivated is sufficiently pleasing; and more dependance can be placed upon the prolongation of life, such birds generally being of robust constitution. Lizard Canaries likewise are sweet songsters, but they are not so much at call as Norwich, which latter breed possesses that much-sought-for colour—"yellow." Everybody, at least ten out of a dozen, wishes for a "yellow" bird, which is supposed to mean clearly a bird without any blemishes—marks upon it. At least that is the way it is interpreted by those outside the circle of "the fancy." In many cases where a marked Norwich may be offered for sale, the reply is "I do not want a Mule."

Now in making choice of a bird to gratify my own taste I would choose a Mule proper—a cross betwixt a Goldfinch and Canary, for the reason that you may obtain a greater variety and change of notes from a young bird when brought up under a good schoolmaster; and I have always looked upon Mule birds of the above particular breed as being more vivacious and entertaining than a Canary.

In maintaining and preserving the constitution of a healthy cage songster it should be kept in a well-ventilated atmosphere, apart from a superabundance of artificial fire heat and from the poisonous fumes of gas. Thereby many good birds become spoiled. Excessive heat brings about periodical moulting, and thus arises the often-asked question "What is the reason of my Canary giving over singing?"

In speaking of "German songsters" Mr. John Varley of Nottingham, in his third edition of "Exhibition Canaries," says:—"In autumn and the early part of winter every year a very many trained, or partially trained little songsters, Canaries and Bullfinches, are brought to England by German itinerant dealers. These Canaries are a short plump race, with full wide chests and very expansible throats while singing, which last property gives them the power to warble in an extraordinary degree. They are mostly bred and trained by the peasantry of the Hartz and Tyrol mountains, who keep and employ sets of well-trained birds as schoolmasters. These schoolmasters consist not of Canaries only, but also Nightingales, Blackcaps, and other of our migratory and home warblers, which are thus used for training Bullfinches to whistle tunes, which they often do very proficiently and plaintively. These Hartz Canary songsters are not generally blessed with very pretty plumage, but their melodious sweetly modulated voices and free song more than compensates for any want of beauty. Some of them have an astonishing range of notes and deflections."

Mr. Varley also says in reference to German birds:—"They are not often exhibited as show birds, but are occasionally used in prize song contests." In this latter remark I can bear out Mr. Varley's assertion so far as the showing of them is concerned. A bird more unlikely for exhibition I know not where to find, although I have had many come under my notice in an "Any other variety" class at the Crystal Palace bird shows.

Mr. Varley in his interesting pamphlet gives the "rules for judging and determining superiority of song." He says:—"In competing for superiority of song, quietude and reasonable distance from the birds to be kept; only one contesting bird should sing at the same time, but the owner may have the privilege of bringing another songster to stimulate his own to sing. The time allowed in case of Canaries, Linnets, &c., should be no longer than fifteen minutes, part of which may be in sight and part out of sight of the stimulator. Superiorities:—Greatest number and variety of good notes; greatest harmony of song; fewest harsh or incongruous notes; greatest length of rolls or runs on the same notes measured by seconds; greatest length of time without breaks, or least number of breaks in continuous song within the given time. Harsh or otherwise bad notes to be recorded by points against. Two judges, two time-keepers, an umpire, and the owner or exhibitor of the bird or his agent, only to be in the room with the birds during the time of the contest."

In making choice of a bird for singing do not pick one with a drooping tendency. The best sign of health is compactness of plumage. The throats of birds when singing should be expanded, as Mr. Varley says "those can warble best which have this property highly developed."—GEORGE J. BARNESBY.

BIRMINGHAM COLUMBARIAN SOCIETY.—The members of this Society announce that their Show of Pigeons will be held at the White Horse Hotel, Congreve Street, on December 3rd, and to which they invite all fanciers visiting the Cattle and Poultry Show.

BAR-FRAMED HIVES AND THEIR MANAGEMENT.

No person of intelligence with an average amount of time at his command who has tried fully and fairly the system of bee management which encourages the use of bar-framed hives, will ever return to the old-fashioned system of straw skeps. The advantages of the new and more scientific principle are so many and so obvious in comparison of the other—as they have been again and again stated in these pages from the days of Mr. Woodbury, its first great advocate here, down to our own times—that it seems scarcely necessary to repeat them; and yet as there is a constant accession to the number of readers of this Journal from among persons who are novices in bee-keeping, and inquiries are being continually made for information on this subject, I purpose to go into the matter from the beginning. I am the more induced to do so because our friend Mr. Pettigrew in a recent number, at page 411, when asked for information on a branch of this subject—namely, as to "the best size for a strong stock in winter, and what height for a frame hive," dismisses the subject with an answer which is by no means complete, and which in fact deals somewhat slightly with the whole question, the truth being that Mr. Pettigrew knows very little practically, as he has often admitted, of this now favourite and increasingly adopted mode of bee-management.

As I have said before, so I say again, that Mr. Pettigrew's system both as to his use of straw hives and his method of management is excellent in its way, and admirably adapted for the one object he has in view—namely, the taking from his bees the largest possible quantity of honey without particular reference to its quality. There is nothing new or special in Mr. Pettigrew's system, as he himself candidly states, except that he finds a much larger hive than is commonly used in the country to be in every way better and more profitable in his own locality. Some of us think that he rides his hobby of big hives somewhat "to the death," as for instance when he insists upon their being equally adapted to all places alike, whether the honey pasturage and supply be good, bad, or indifferent. I do not suppose he exactly knows the meaning of the word "illogical" when he applies that epithet to the statement that "large hives are best for good neighbourhoods and rich pastures, and small hives are best for unfavourable localities for honey." This self-evident axiomatic truth surely needs no proof. If all places were alike in excellence and productiveness of pasturage then the biggest of big hives "for ever;" but where, as in my own case, the pasturage is scanty and unproductive, such very large hives like Mr. Pettigrew's are worse than useless. I have abundantly proved it to be true.

Be it remembered that the dispute is not as between straw and wood as materials for hives. Straw is a most excellent material, and far better than wood, in all places where the hives are exposed to severe cold, save only where proper precautions are taken to protect wooden hives. This can very easily be done by a variety of contrivances, such as by covering with other boxes and filling the interstices with chaff or sawdust, or protecting with old carpet jackets, &c. If this care be taken I can see no sort of difference in the intrinsic excellence of the one material over the other; I mean simply as to which is best for the comfort of the bee. I once thought that hives of straw were drier than hives of wood. I have long given up that notion, except in the case of quite new wooden hives. It is the habit of bees to smear over everything with a kind of varnish of propolis. It matters not, therefore, whether a hive be of straw or wood. After the first year's use any moisture the bees may occasion inside the hive will have precisely the same effect on the combs in the one case as in the other. It will run off from the sides downwards equally in both cases. In both cases it will affect the combs for harm exactly in the same way. If the hives are equally well peopled, equally well protected from external damp, equally well situated so as to be affected alike by any dry currents of air, they will pass through the winter precisely as well in the one hive as the other. That is the result of my own experience of more than forty years as a bee-keeper. Therefore I say that on the score of dryness there is not a pin to choose between wood or straw. I have seen straw hives with the combs as damp and mildey as in any wooden hives I ever saw, and the latter hives I find practically quite as excellent domiciles for bees as anything that could be wished for. The one

advantage of straw over wood is, that it is both warmer in winter and cooler in summer. But this advantage is far more than counterbalanced by the superior handiness and durability of hives of wood, whether they be hexagonal, square, or oblong in shape. The latter always retain their form, whereas after a time the best-made hives of straw give way more or less, and are then almost useless where accuracy of measurement is wanted.—B. & W.

DORSET POULTRY, PIGEON, AND CAGE BIRD SHOW ought to be attractive and successful, for nearly £300 in prizes are offered, including thirty silver cups and pieces of plate.

OUR LETTER BOX.

CRYSTAL PALACE POULTRY SHOW (E. Cross).—The prize-list was certainly not clearly worded, and was liable to be mistaken.

PURE BREEDING (Kendallian).—The question you ask is a vexed one, as opinions vary very much. Are the hens laying now? If they are it is safe to doubt their eggs at any rate until the end of the laying, whereas if they were now put to the cock you wish to breed from, no other allowed to run with them, and they are only at the beginning of the laying, the later eggs may in our opinion be trusted. But seeing the time of year, the few birds that are laying, and the time that must elapse before they can be hatched "chickens of 1878," we advise you to take some that are not laying, to put them with their intended partner, and to set the eggs after the first four or five they each of them lay. We believe then you will have the strain you wish for.

WASPS (C. A.).—The annoyance from the nest of wasps in the wall of one of your bedrooms must have been great, but as the lives of working wasps are very short, like those of working bees, it is to be hoped that the annoyance is at an end. Though working wasps live but a few months their queens live longer, and singly nestle and hybernate in some protected corner. A great number of queens are bred in autumn in every nest of wasps, and probably those bred in your wall have already gone to hybernate elsewhere. By closing the outer entrance to the nest your house will not be invaded next year by wasps. This season has been rather cold and unfavourable for wasps. But few queens in the north were able to establish nests, hence wasps have not been numerous. Next spring boys and girls should be offered 6d. for every queen wasp caught and killed.

REMARKS.

- 21st.—Fine morning, cool, rain began at 10 A.M., wet and dull afterwards; very wet evening.
 22nd.—Fine morning with hot sun, heavy showers during the day; high wind at night.
 23rd.—Fine bright day; lightning at 7 P.M.; lunar halo at 10.30 P.M., cold starlight night; thunder at night.
 24th.—Dark but fine morning, rain commenced at 11 A.M. and lasted nearly all day; very wet afternoon.
 25th.—Fine cool day; starlight night.
 26th.—White frost in morning, and very fine; dull afternoon, rain began at 4.30 P.M. and continued the rest of the day.
 27th.—Damp but fine morning, cloudy afterwards; heavy rain from 5 to 7.30 P.M.; very fine after 10 P.M.
 A wet week, with frequent high wind.—G. J. SYMONS.

COVENT GARDEN MARKET.—NOVEMBER 28.

Our market is still very dull, and will be till a week or so before Christmas. Prices remain the same.

From observations taken near London during forty-three years, the average day temperature of the week is 46.6°; and its night temperature 35.1°.

ROOTS AND LEAVES.

IT is not sufficiently borne in mind that there is a close sympathetic feeling between the two extremities of a plant. The leaves cannot be injured materially without the roots being checked, and *vice versa*. Generally speaking, but there are exceptions, while a leaf has the smallest particle of green colour in it, it has a duty to perform in the plant's economy, and to remove it by force is to upset the natural arrangements for assimilation. Sometimes this is admissible, as the benefits arising therefrom more than counterbalance the injury done; but there are times when the injury would preponderate, and I think this is especially so when the circulation is becoming sluggish as in autumn, or when a plant is unhealthy and short of good foliage.

There are people I know who do not like to see the "sere and yellow leaf," but they must endeavour to put their dislikes on one side if they would become skilful cultivators. Depend upon it half a leaf in the growing season is better than no leaf at all, even as half a lung would be better than none at all; and remember also that when the wood is ripening the roots are, or ought to be, doing the same thing, but they are both dependant on the foliage, and no real ripening can take place after it is gone. We know that people, and good gardeners amongst them, do brush-off the loose leaves from their Peach trees in autumn with the idea of admitting sunlight to the wood to ripen it. But is not this a fallacy? The wood may get a little coloured, but it never gets the least harder after the foliage is gone. Ripening can be assisted considerably by stopping the young growths in July and August and by exposing the foliage as much as possible at that time to the light; but if anyone supposes he can assist the ripening of the wood of the current season by mutilating the trees at either end after September, however fine the autumn may be, I think he is mistaken.

There are many people, too, who trim off leaves for the sake of tidiness when they begin to look a little dingy; herbaceous plants sometimes have not only their leaves trimmed off, but their stems also, before they are anything like ripe or have made provision for forming fresh stems. This is clearly a mistake. We must put up with a little unsightliness at times and allow the plants to ripen naturally as much as the season will admit, only cutting off that which is actually dead, especially when dealing with weak or tender subjects. Ferns are sometimes cut clean down when they are past their best. "Yes," says some successful village exhibitor, "by those who grow them better than you do." Granted; but that does not prove the plants could not be grown better by leaving the fronds on, in the case of evergreen sorts, till the young fronds had grown up and become fitted for their work.

With regard to deciduous plants either for flowering or fruiting, many people would seem to think that if they

can by any means—let it be by starvation, freezing, or scorching—but get rid of the foliage all must be right and that the wood is ripe as a matter of course. But the fall of the leaf is not an infallible sign of perfect ripeness. The natural fall of the leaf is early this year, and I have no doubt many are consoling themselves that the wood of their fruit trees is, owing to the fine September and the light crop of fruit, matured better than usual, but such is certainly not the case. We will endeavour to be very grateful for the fine September; it did an immense deal of good in many ways, but it could not counteract all the bad effects of a cold dull summer, and it still left much of the wood unripe, therefore it will be necessary to prune hard. I think it will be generally found that a period of hot weather coming just after the spring growth is made is best calculated to ripen outdoor fruit trees, and to bring good flavour and well-coloured fruit; and I also think that when the wood is well ripened the autumnal colours of the foliage are brightest. There has been a great lack of colour this autumn.—WILLIAM TAYLOR.

SELECTIONS OF GRAPE VINES.

Now is the time to select Vines for planting during winter and spring, and those who have them to buy cannot do better, nor purchase cheaper, than by obtaining them from a respectable nurseryman. Sometimes some people are induced to purchase a few half-grown things from a neighbour because they get them cheap; but cheap inferior Vines for planting are very much more expensive in the end than purchasing almost at any reasonable cost first-class Vines. Small badly-grown Vines are a long time in making good fruiting canes or rods; whereas when good Vines are planted they bear fruit the second year and good crops the third. First-class canes for planting of all Vines that have been in commerce for some years may be bought from 5s. to 7s. 6d. each. Vines at this price should be nearly as thick as one's little finger, from 4 to 6 feet long, every inch of wood hard and brown, and, above all, the roots should be wiry and so plentiful that they will hold the ball of soil together when lifted out of the pot and swung about with the hand. As to insects no warning need be given, as I do not suppose anyone would be so foolish as to plant Vines covered with any kind of injurious insect; but at the same time when Vines are ordered without seeing them it should always be on condition that they are perfectly free from every pest.

Vines are generally required of three classes—for a cool house, a temperate house, and a hothouse. A cool house may be a proper vinery not heated, a greenhouse, or conservatory; a temperate house is generally a vinery with two or three rows of pipes in it; while the hothouse is one with strong forcing power, such as that which Muscats are grown in. To meet each of these frequent requirements I will arrange the Vines as follows:—

Vines for a Cool House.—Black Hamburg and its varieties, Royal Muscadine, Mrs. Pince's Black Muscat, and Lady Downe's—that is, two early and two late sorts.

When only one is wanted take the first. This season we had it perfectly ripe in a house where there is no means of applying heat by the end of September, and a gentleman told us that the berries were finer coloured than any of the Black Hamburgs at the Carlisle Show.

Vines for a Temperate House.—The above may be included here as well as the following: Black Alicante, West's St. Peter's, Foster's White Seedling, Gros Colman, Duke of Buccleuch, Golden Queen, Syrian, Trebbiano, White Nice, Duchess of Buccleuch, and Dr. Hogg.

Vines for a Hothouse.—Muscat of Alexandria, Bowood Muscat, White Frontignan, Madresfield Court, Canon Hall Muscat, and Gros Guillaume.

A few more varieties might be added to each of these classes, but as a rule none are of equal merit to those named. The average temperature which would ripen each of these classes might be taken at or between 60°, 65°, and 70°.

There are other three classes into which these Grapes may be conveniently divided to meet general wants. These are:—*Early Grapes*—Black Hamburg, Foster's White Seedling, Buckland Sweetwater, and Duke of Buccleuch; *Midseason Grapes*—White Frontignan, Madresfield Court, Muscat Hamburg, Dr. Hogg, Duchess of Buccleuch, and Canon Hall Muscat; *Late Grapes*—Muscat of Alexandria, Lady Downe's, Black Alicante, West's St. Peter's, Gros Colman, Golden Queen, Gros Guillaume, Syrian, White Tokay, Trebbiano, and White Nice. With the exception of Muscat of Alexandria we have ordered all the sorts here named to plant a late vine with this winter, and we would have ordered the Muscat too only we have not enough of heat in the house to grow it properly. Golden Queen may be said to be the only one that is on its trial, and I believe it is understood to be a good Grape; but at the same time, if its keeping qualities are so good as represented, the month of September is a curious time of the year for prizes to be offered for a late-keeping Grape. Showing it well in prime condition in February or March would do much to establish its reputation in this respect.—A KITCHEN GARDENER.

WINTER EMBELLISHMENT OF FLOWER BEDS.

MANY able critics have justly described our flower gardens in winter as cheerless and barren. We must admit that they are so in most cases, for it is seldom that the parterre is occupied with ornamental plants except in the height of summer. This winter decoration of flower beds is a subject which deserves more attention than it has hitherto had. When the summer is over the empty beds always produce a depressing effect. Little can be expected in winter in the way of flowers, but many hardy shrubs and Conifers are well suited to render the beds attractive. Until the return of spring many hardy evergreens are so distinct and beautiful that they would, if employed, soften the rigour of winter and assist in making our pleasure grounds pleasing all through the year. Conifers alone, with their great diversity of colour and habit, are capable of forming ornamental groups. Who could look upon a bed of young plants of the *Cedrus Deodara* with their graceful forms without admiration? *Cupressus Lawsoniana* is particularly attractive with its varieties *aurea* and *argentea*. The round form of the *Biota aurea*, with its brilliant golden tinge, is both elegant and bright; then again, as a contrast in form we have the upright habit of growth with equally brilliant hue of *Biota orientalis elegantissima*. The Irish Juniper and the Italian Cypress are compact in habit and extremely chaste.

The Junipers ought to take the lead for bedding, for they are most elegant when in a small state, and the best for the purpose is *Juniperus virginiana glauca*, with its charming silvery shoots, slender and delicate; *J. virginiana pendula* kisses the ground, and *J. virginiana erecta* is as upright as an Irish Yew, but of a lively tone of bluish green; *J. phoenicea* is of a free branching habit, a mass of delicate green tracery; *J. Sabina variegata* is charming to plant as a carpet for a tall specimen of *J. chinensis* or *J. excelsa*; *J. fragrans* is very beautiful in a small state; and *J. drupacea*, with its rigid leaflets, is suggestive of a miniature *Araucaria*. All the Conifers named may be purchased at a low price and in quantities. They are better for being grown in pots for bedding, for they can then be easily removed to and fro and replanted without being injured; thus they may be made to do duty in the parterre through the winter, and contribute to the beauty of some other portion of the grounds during the summer; or they may be placed in the

reserve garden till wanted. With ordinary care and attention they will improve in beauty and value yearly, and when grown too large for the pots and beds they may go to beautify the shrubbery.

Many of the commoner shrubs can be made objects of beauty by the exercise of a little taste in planting them in beds. They can be grown without pots and without risk of being injured by transplanting provided proper care is taken in their management. The Hollies are amongst the most useful for this purpose. They bear cutting, and can be grown as standards, pyramids, or any other shape that taste may dictate. The variegated kinds cause the best effect, particularly when laden with red or yellow berries, as we see them this season. The *Berberis*, or *Mahonia* as it is now called, is admittedly one of the most beautiful of evergreens. At this season its rich dark foliage is quite distinct. The Golden Yews are also well adapted for planting in beds when in a small state, and shine more conspicuously in a group than a mixed shrubbery; and we must not forget the *Aucubas*, for they contribute cheerfulness wherever they are seen. The *Laurustinuses*, with their ruby buds and white flowers, are as fresh and bright as the summer flowers. They give effect the moment they are bedded, and continue attractive for a length of time. The same may be said of the *Arbutus* or Strawberry Tree. The next in utility among hardy shrubs are the various kinds of *Euonymus*. It is astonishing how much variety may be attained by the varieties of this plant alone. We have *E. japonicus*, *E. angustifolius*, *E. argenteo-variegatus*, *E. aureo-variegatus*, *E. latifolia albo-variegatus*, and some others; but *E. radicans variegatus* is perhaps the most useful of all. It is a prostrate-growing species, excellent for edging, the constancy and beauty of its silvery white variegation, which is occasionally tinged with pink, giving it a striking appearance not possessed by any other plant. It is highly suitable for winter decoration, and is a general favourite. There are many more ornamental shrubs that might be used with a good effect, such as the Variegated *Buxus*, *Daphnes*, *Osmanthus*, and others which may be turned to valuable account, yet I do not advise the planting of the whole of the beds with shrubs. We must have a good share of them planted with bulbs and other spring flowers. My object is to show that people, after gratifying their taste with gay flowers in summer, need not have barren gardens in winter.

In arranging the shrubs we must be guided by the number of beds and the scenery around them; for instance, if there are only one or two beds, and these not in the neighbourhood of a shrubbery, the beds may be planted on the mixed system; but if there are many beds, and in close proximity to a mixed shrubbery, we must not plant more than three kinds in a bed thus—the principal groups, the edging, and the carpet. Even if the beds are numerous they may all be made distinct without giving a shrubbery-like appearance to them. The following examples are submitted as effective arrangements:—

A bed of Golden Variegated Holly, a carpet of one of the dwarf Junipers, with a margin of the Silver *Euonymus radicans*.

A bed of standard Silver Hollies, a carpet of the Golden Box, with an edging of Variegated Ivy.

A bed of *Cupressus Lawsoniana*, a carpet of small *Aucuba*, with an edge of *Erica herbacea carnea*, *E. vulgaris aurea*, or *E. mediterranea*.

A bed of Golden Yews, a carpet of the silver-leaved *Euonymus japonicus albo-marginatus*, with an edge of *Vinca elegantissima*.

We can exercise our taste to any extent and execute some bright examples of shrub embellishment, which will impart a cheerful tone to the garden in the depth of winter.—NATHAN COLE, *Kensington Gardens*.

HELLEBORUS NIGER.

ALLUSION having been lately made to this interesting hardy plant, I may remark that I recently observed a very fine specimen in an amateur's garden. The garden alluded to was partly in grass, with a belt of evergreen and deciduous shrubs at one side, and between these shrubs, or rather in front of them, this Hellebore was growing, and it had evidently not been disturbed for several years; for at the time I met with it, it was a dense mass of foliage, about 4 feet in diameter, with scores of flowers of the very purest white, quite equalling the *Eucharis amazonica*. They were just on the point of expanding during the last week in November, and some that had been gathered opened in water, while the others were opening on the plant. I certainly never met with so fine

a plant, and could not ascertain how long it had been undisturbed; as I believe it is only in the gardens of cottagers or in those of amateurs that have partly been neglected of late years that we find this plant in such good condition as the one mentioned above. The attempt to propagate is often too great to be resisted by the more fashionable gardener of the present day, so that but comparatively few large specimens are met with.

It was growing on a deep yellow loamy soil, and almost touching it was a *Hydrangea* that annually flowered a very good blue, but the appearance of the soil was the very reverse to peat, although *Rhododendrons* seemed to thrive pretty well in it. The soil to my mind resembled the dried-up mud of a pond, which it possibly might have been. The flowers of the *Hellebore*, I may add, had not the least tinge of pink about them, which many others that I have met with have, and the foliage of the plant was both ample and luxuriant, and its flowering nearly a month before Christmas in the present year is only in accordance with that of several other early spring flowers, as many *Primroses* and not a few *Polyanthuses* are in full flower, which no doubt is due to the moderate rainfall we had at various times during the summer.—J. ROBSON.

REMOVING TREES.

THE following remarks will, I trust, be of service to some young gardeners and others who may have trees or shrubs to move, and with poor facilities for the undertaking. Few employers will go to the expense of hiring or buying barrows and other tree-movers, consequently some other cheaper if less effective appliance must be adopted. November is generally considered the best time for moving all kinds of trees, deciduous or otherwise. We, however, moved trees during intervals of favourable weather throughout last winter as successfully as those moved in November. We were re-arranging a shrubbery or arboretum formed about nine years ago. Among others we moved specimens of *Piceas Nordmanniana*, *grandis*, and *Pinsapo*, *Cupressus funebris* and *Lawsoniana*, *Salisburia adiantifolia*, *Thujas*, *Abies*, *Thuopsis borealis*, *Sophoras japonica* and *pendula*, *Acacia tortuosa*, *Phillyreas*, *Hollies*, *Portugal Laurels*, &c. Of course there were failures, notably with *Cedrus Deodara* and *Arbutus Unedo*, but in neither case was a ball obtainable, and seldom is unless prepared by digging a trench round the previous year, the roots being inclined to ramble and make but little fibre. Many of the trees were a fair size, but the largest and best specimen successfully moved without any previous preparation was a *Wellingtonia gigantea*, the height of which was 20 feet, and fairly proportionate.

I will briefly detail our method of procedure in this instance, the same plan (according to the size of tree) being adopted with the others. The soil and subsoil varied considerably, but clayey loam was most prevalent. This was greatly in our favour, as where there is any great amount of sand or gravel the ball is apt to crumble away. The ball of the *Wellingtonia* consisted principally of the clayey loam, clay predominating. We commenced operations by carefully tying up all the lower branches, drawing them as much out of the way as possible. A circle was next marked round the tree about 6 feet from the stem, and inside of this a trench 2 feet wide was taken out. The men were facing the tree, and using spades when cutting the outer ring. After this they had the tree always on the left or right hand as the case might be, and dispensed with the spade as much as possible, using forks and picks where necessary. This was done to save as many roots as possible, those farthest from the stem being the best, and were taken great care of. We continued this till we were well below the principal roots and intended ball before commencing its reduction. This rule should always be strictly followed, as it greatly facilitates all after proceedings. The men are generally in too great a hurry to get the tree out, but by allowing plenty of depth and width much labour is eventually saved and success is more likely to ensue. We then commenced undermining with the picks, gradually working-off small pieces from the ball (large pieces bring away too many roots), keeping the trench clear with the shovel. This went on until we were within about 2½ feet from the stem. The surface soil was then pricked off till the roots were reached (this helps to prevent cracking); all the roots, where practicable, were pegged to the ball, and the longer and stronger ones tied to the stem. We undermined the ball until only a small pillar of soil remained and then inserted our slides.

These were made of deal, were 7 feet long, 4 inches thick, and 8 inches wide; they were rounded off from the centre to enable them to run freely, and the bottoms shod with old cart tires. This is necessary, or the roads will tear them to pieces. Strong bolts with eyes and rings for drawing purposes were inserted in the inner side of each end, and two strong bolts were made for connecting and tightening the slides. These were 3 feet long, square at the head, screw ends and the nuts had a small handle attached for tightening purposes. The sockets were square, with iron plates on the outer sides, and were placed in the centre of the wood about 15 inches from the ends. The way out, kept clear from the commencement, was sloped off to an easy rise, the slides adjusted accordingly, and so as to nicely balance the ball, were screwed up, and the remaining soil then worked from under the ball, allowing it to gradually settle on the slides. This was "ticklish" work, and was done with a crowbar and long heavy chisel. Two wedge-shaped boards were worked in before and behind the ball, and planks under the slides to improve the running. Three horses were required, a man at the head of each (to prevent snatching, broken chains, &c.), and the tree firmly bound to the slides was then drawn out and away to its present site, previously prepared, a sloping inlet made, &c.; the horses were unhooked, taken to the opposite side, long and strong chains attached, and it was soon in. The bolts were withdrawn, the slides undermined and taken out, and the "worst was over."

We then unpegged and cleanly cut the ends of all the roots, taking out all those badly damaged. They were then laid on the soil as filled in, every one in its proper place or level. The ball being rather dry was pierced with pointed iron rods and thoroughly soaked, not by heavy but frequent waterings. Had the ball been in a moist condition no water would have been used, as the surrounding soil was in good condition, and I think it a great mistake to saturate newly-planted trees; they will "settle" fast enough. We made the balls as flat as possible, to enable them to more readily unite with the soil, and they are less likely to get out of the perpendicular. All the holes were well prepared, not mere basins, to fit the ball, but ample space was given, the soil thrown out, the subsoil broken-up with a pick, and good soil, principally from an old rubbish heap, was added. The trees in most cases were planted rather above the level, as this gives a greater depth of good soil, and consequently the roots are longer reaching an unkindly subsoil.

Slides on a smaller scale would, I think, be found very useful for moving small specimens, as two or four men can lift out and carry or draw them to fresh sites without having to wriggle or twist them about to get planks, hand-barrows, or whatever is used under and away from them again. Slides have, I believe, long been in use, but I have never seen any but those I have had made. They certainly answered our purpose remarkably well, but anyone with a better and equally simple invention will greatly oblige me and doubtless others by describing it.—W. IGGULDEN, *Orsett Hall, Essex*.

RAIN-PROOF BEDDING PLANTS.

1877 has been an exceptionally wet year all over the country, and throughout the season its effects have been shown on few things to a greater extent than on summer bedding plants. Gorgeous masses of colour, and magnificent displays from May to September or October, have been few and far between this year; and however much *Geraniums*, *Calceolarias*, *Verbenas*, and other half-tender plants may have been petted and held-up as infallible, I fear this season must have brought them into general discredit. But in saying this let it be understood that I do not despise summer bedding. Hardy herbaceous plants are all very good in their place, but those who advocate filling our flower garden designs with a mixture of such plants must be regarded by the general community as showing worse taste than that which they condemn. What I mean doing, and what others will find it to their advantage to do, is to make the flower garden as gay as it possibly can be made with bedding plants in summer, and only employ such plants that will make and retain a gorgeous display independent of either sun or rain. *Geraniums*, *Calceolarias*, *Verbenas*, and such like cannot be relied on to do this, but there are other plants equally gay which can.

During the past summer the popular trio named would count five to one of all other plants put together in our flower garden. Next year I will take care that these other plants

count ten to five of the Geraniums, Calceolarias, and Verbenas. The latter grew well—too well, as they exceeded all proportional bounds, and after a week's sunshine they did make a pretty good display; but one hour's rain completely demolished it, and this occurring repeatedly brought the minority of our plants into prominence and favour. These consisted of Violas as flowering plants and some rich-foliaged plants.

Viola blooms are the very best flowers in existence for withstanding rain, and the length of time they remain in bloom and the quantity of flower they produce throughout the season is surprising. They begin blooming early in May and continue a perfect mass until the end of October, let the weather be either excessively cold, warm, or rainy. They always maintain a low compact habit of growth, and for "show," Geraniums, Calceolarias, and Verbenas at their very best cannot "put them in the shade." These remarks do not apply to or reflect the opinion of one season nor one district, but to a good many years now and many localities north and far south. Apart from all this Violas have another strong, very strong, recommendation—they are easily propagated, and the most simple of all plants to cultivate. They will root and grow in any ordinary soil, and in winter they must either have the protection of a cold frame or the shelter of a wall, but what they must never have is expensive artificial heat. Cuttings may be inserted during any of the autumn months, and those who cannot incur the trouble of doing this may leave the old plants undisturbed in autumn and divide them and plant afresh in April, about which time they may all be planted in the positions they have to embellish during the summer and autumn.

The following are the names of those which I have found of superior merit. They are classified according to their leading colours:—*White*—Climax, Snowdrop, Pearl, Purity, Pilgrim Park, Snowflake, and Stricta alba. *Purple*—Vanguard, The Tory, Prince of Wales, The Favourite, King of Bedders, Dickson's King, Alpha, Acme, and Emperor. *Yellow*—Brilliant, Canary, Dickson's Golden Gem, Grievi, Sovereign, and Stricta aurea. *Lilac*—Lilacina and Multiflora amabilis. *Violet*—Royal Visit, and Amena magnifica.

Other "rain-proof" bedding plants capable of making an attractive display are the different sorts of Iresines, Mesembryanthemum cordifolium variegatum, and the yellow Pyrethrum. One of the finest beds in our flower garden this season was one in the form of a scroll and about 2 feet wide. The centre of this was filled with Iresine Lindeni edged with the Mesembryanthemum. Two other effective beds were centred with Iresine Herbstii and edged with Pyrethrum. All these plants make excellent combinations with the Violas. These fine-foliaged plants were attractive from the day they were put out in May, and although much rain has fallen lately they were just about as showy on the 24th of November as they were in August. The Pyrethrum is easily raised from seed, which may be sown now in a little heat to furnish plants for planting out in April. Iresines are so easily propagated that a plant may be raised from every joint. The Mesembryanthemum is a plant that may be raised true from seed, and hundreds of cuttings may be had from a few old plants lifted in autumn and kept in a temperate place until spring. Perhaps there are other foliaged plants which might be added to these, but those who employ the plants named will not have cause to complain of the rain spoiling their flower garden.—A FLOWER GARDENER.

ROSE SHOWS.

I SINCERELY hope that the National and every other metropolitan show committee will carry out the suggestion made by "A LOVER OF ROSE SHOWS," and provide classes for nurserymen and amateurs living within a short distance of the City.

There is one other point in the arrangement of Rose show schedules which has always somewhat surprised me—that is, that, unlike almost all dog, poultry, and other shows, the names of the judges are never printed thereon. I think if they were it would be a guide to intending exhibitors. In this way "WYLD SAVAGE" wrote in the Journal a short time ago—"Mr. Turner has several times spoiled his stand by putting in a treble of Paul Neyron," or words to that effect. Judging from this I should suppose that Mr. Turner likes this Rose, and that "WYLD SAVAGE" very much dislikes it; therefore, if I saw from the schedule of a show at which I intended to compete that "WYLD SAVAGE" was to be the principal judge

I should not put in a Paul Neyron if I could possibly get another Rose, while, on the other hand, if I saw Mr. Turner's name as leading judge, if I had at all a decent bloom of this variety I should insert it. There are many other cases in which the knowledge of the names of the judges would be of assistance to competitors.—EXHIBITOR.

THE CLEMATIS.

CLEMATIS are all beautiful, and are becoming so numerous that the time has arrived to make selections instead of forming exhaustive collections, at any rate for gardens of ordinary extent.

Who is there that does not admire our own native wilding *C. vitalba*, better known in some localities by its familiar title of Traveller's Joy? I have seen old lodges over which it has crept completely enveloped in a cloud of its long silvery bearded seed clusters, and it is even more ornamental when hanging, as it sometimes does, in wreaths and festoons among the branches of trees. It sometimes rambles so far and forms such a dense tangled growth, that in some parts of Kent where it is thus found growing among the underwood the woodcutters term it "Poor Man's Hindrance." Not only for woodland walks should it be employed, but any suitable position, however prominent. I saw nothing more beautiful at Pentilie Castle in Cornwall than a huge cluster of it that had climbed over an old tree in the midst of the dressed grounds.

Equally beautiful in its way—much more so in the eyes of many, but with a beauty that is more fleeting—is the Himalayan species, *C. montana*. Its white flowers open in spring in such dense clusters that they may be compared to a snow wreath, and, unfortunately, in unfavourable weather the comparison holds good as to their duration. Such was the case in the spring of the present year, but usually they continue in full beauty for some weeks. It grows with singular rapidity, and its stout pliant branches possess the important merit of retaining the abundant foliage in its green state throughout winter. Another familiar old species—very old, but worthy to rank with our choicest hybrids, is *C. flammula*, brought over from France ages ago. Its so-called white flowers have a decided yellow tinge, cluster quite as thickly as the Indian species, are in full beauty in August, and, best of all, have a delicious and delicate perfume.

Few genera have a wider distribution, almost every country having one national species, some many. North America has its Traveller's Joy; Japan, among numerous other floral treasures, gives us *C. florida* and *C. patens*, from both of which we have numerous garden hybrids, and a still greater number from the Chinese species *C. lanuginosa*.

Coming back to Europe again we have the Spanish species *C. viticella*, which with its four varieties *cærulea*, *plena*, *purpurea*, and *tenuifolia* has long been known in this country, and from these, too, we have some few fine garden hybrids. I am not, however, writing a history of the Clematis, and need not therefore enumerate species that are more curious than ornamental, or which have become insignificant beside the varieties raised during the last eight or ten years, and of which I may now usefully select a few worthy to associate with Jackmanni. Of such I will take Miss Bateman, a spring-flowering variety of the *patens* type, with white flowers having a central stripe of pale yellow along each petal. *Velutina purpurea*, of the Jackmanni type, very dark in colour, which may be described as a rich dark crimson. Lord Lonsborough, with rich mauve-coloured maroon-striped flowers. Mrs. S. C. Baker, a charming kind with pretty delicate pink flowers. The Queen, another of the *patens* type, with pale lavender flowers. Thomas Moore, a distinct and novel variety with flowers of a peculiar and pleasing shade of violet, and with white stamens. Fair Rosamond, a sweet-scented variety with pretty white flowers tinged and striped with red. Vesta, creamy white, with conspicuous dark stamens. Lucie Lemoine, with fine white double rosette-like flowers; and the still finer double lavender-blue variety Countess of Lovelace. There are some dozens of others ranging through a wide gradation of colour which cannot be noticed here, and I will add no more to the few choice kinds I have named, for if I were to begin wading among the many shades of crimson, lavender, purple, and white it would only serve to confound those whom I wish to assist.

A very general and ardent wish to understand and master its propagation is a natural outcome of the popularity which the Clematis now enjoys; and among the several methods that

have found favour I do not remember seeing mention made of the simplest and best way of all, and that is to take cuttings of the tender young shoots in spring, cutting them to a joint as you would a Geranium or Verbena, and dibbling them in silver sand under a bell-glass. I have done this, and by way of trial put some in a stove, some in a hotbed, and others in a vinery, and all of them grew readily enough. The cuttings were taken from plants of Jackmanni and Prince of Wales growing in the open air, but the weather had been very genial, and no cold cutting winds have blasted or browned the young growth. For greater certainty, if I wanted a quantity, I should prefer some old plants in pots kept entirely under the shelter of a glass house or pit for that especial purpose.—EDWARD LUCKHURST.

MESSRS. OSBORN & SONS' NURSERY, FULHAM.

A FERTILE soil and a position well sheltered by trees are important advantages possessed by this old-established nursery. That it is an old nursery and the soil good is sufficiently testified by the age and size of a few ornamental trees, the remnants of "stock" which was planted in the grounds generations ago. Some of the glass structures also savour of antiquity—they are possibly octogenarians—while there are others of more modern date, middle-aged structures, stout and strong, and others, again, are comparatively new; but all are occupied, and well occupied, by plants also old and new, for old plants are not despised any more than new introductions are overlooked. It is meet that it should be so, for it is an old firm with a young head, and is not at all likely to lose its "matured" character, nor to be in any other position than "well abreast of the times." Therefore if the business is old it is healthy; everything about the place denotes that—the trees, the shrubs, the flowers, the absence of weeds, and the brisk business movements of the officials—all indicate health; the familiarity of the name, too, to readers of gardening literature, and the position of the firm at leading exhibitions, are evidence also of enterprise.

The Fulham Nursery was established by Christopher Gray about the beginning of the last century. Catesby, Collinson, Miller, Dr. Garden, and other eminent botanists and travellers contributed many rare plants, and great part of Bishop Compton's collection was purchased by them from the Bishop's successor. The first *Magnolia grandiflora* was planted here; the original tree, the parent of most of the older trees of this kind in the country, died some years ago. Its trunk measured 4 feet 10 inches in circumference, its branches extended 20 feet, and it was as many feet high. This nursery passed successively from Gray to Burchall, and from him to Messrs. Whitley, Brames, and Milne to the Osborne family.

The nursery is not a large one—that is, it is not a gigantic establishment; neither is it a small one. Its area exceeds twenty acres, chiefly devoted to the cultivation of ornamental deciduous trees and fruit trees, an equal extent of ground at Sunbury being mainly occupied with Conifers, evergreens, Roses, &c.

Perhaps the most striking objects in the nursery are the old trees, the most prominent of which is the original specimen of the Fulham Oak (*Quercus Fulhamensis*). This tree was figured in Loudon's "Arboretum" forty years ago, and was then "75 feet high; the diameter of the space covered by the branches 54 feet, and the diameter of the trunk at 3 feet from the ground 3 feet 10 inches. There is a great similarity between the foliage of this tree and that of the Lucombe Oak. But however alike the trees may be in foliage they are very different in their habits of growth, the Fulham Oak being a branching tree, with a round head and a comparatively smooth though still somewhat corky bark; and the old Lucombe Oak growing with a straight erect trunk, regularly furnished with branches, and forming both in its young and old states a conical spiry-topped tree, with a more rough and corky bark than the other. In the Fulham Nursery there is a full-grown tree of the old Lucombe Oak, as well as one of the Fulham Oak, which strongly display the characteristic difference between the two trees. The age and origin of the Fulham Oak are unknown; but Mr. Smithers, an old man who has been employed in the Fulham Nursery from his youth, and who remembers the tree above forty-five years, says that it always went by the name of the Fulham Oak, and that he understood it to have been raised there from seed. We have examined the tree at its collar and down to its main roots several feet under ground, and from the uniform texture and thick corky

character of the bark we feel satisfied that it is not a grafted tree. In fine seasons this variety produces abundance of acorns, from which many plants have been raised. These plants, though they have the leaves more frequently broad and dentate than narrow and sinuate or pinnatifid, yet vary so exceedingly that they could hardly be sold as the genuine Fulham Oak. Hence that variety can only be propagated by grafting, and the stock ordinarily used is the common Oak, on which the Fulham Oak takes as freely as the Apple does on the Crab." According to that account the tree must be nearly or quite a hundred years old. It is a splendid specimen, still healthy and vigorous. Yet notwithstanding the close examination and verdict recorded, the tree is undoubtedly grafted, for a branch of the common Oak is now growing from the trunk close to the ground, which settles the point.

Amongst other noteworthy trees in this nursery we observed *Magnolia Thompsoniana*, a real old timber tree, also a striking standard with rugged arms of *Wistaria sinensis*, which must be a "picture" when in flower. There is a fine example of *Sophora pendula*, and a remarkable specimen of the American Nettle Tree (*Celtis occidentalis*). *Gymnocladus canadensis*, *Koeleria paniculata*, *Diospyros Lotus*, and *Laurus Sassafras* also merit notice.

The glass structures are tolerably extensive. Near the entrance to the nursery is a very large span-roofed house which at the time of our visit was occupied with a clean and healthy collection of decorative plants in various sizes, some large, some small—*Cordylines*, *Phormium tenax variegatum* in fine colour, Palms, Tree Ferns, Yuccas, *Aracarias*, &c., with flowering plants of *Gloxinias*, *Fuchsias*, and some fine specimens of the new Musk, *Mimulus moschatus Harrisoni*, which is not only powerfully scented, but is attractive by its bold bright flowers. On the roof are trained *Tacsonia Van-Volxemi*, *Clematises*, and other climbers. Under the stage of this house is a large mass of the old Cape bulbous plant *Anomatheca cruenta*. It appears to be quite established, and has grown in the same place for many years without having received any cultural attention. Even in that semi-dark place it grows freely, and its rich crimson-scarlet flowers are much esteemed for bouquets. This plant is nearly or quite hardy, and it is a little surprising that it is so seldom seen in gardens. It was introduced from the Cape of Good Hope in 1830. The elegant Bladder Fern, *Cystopteris fragilis*, also grows wildly under the stage of this house.

Connected with this structure is a long range of lean-to houses filled principally with Palms and a general collection of stove plants and Ferns. Palms are extensively grown, medium-sized and small plants of the most useful and popular kinds. *Areca Baueri* is distinct by its dark fronds and appears to be in great demand, as also is *Areca crinita*. There is also a fine stock of Mr. Herbst's new Palm, *A. Herbstii*, very delicate in colour and elegant. *Versaffeltias* in variety, *Kentias*, and *Cocos Weddelliana* are well represented. Of the last-named and graceful Palm there are some hundreds of plants in small pots, a valuable stock of one of the most attractive of the slender-growing Palms, and in fine contrast with it is the boldly majestic *Stevensonia grandifolia*. The house also contained the best of the *Crotons* and *Caladiums* and other fine-foliaged plants, also a stock of a richly coloured broad-spined variety of *Anthurium Scherzerianum*. At the back of the range is the fernery, where a collection of Ferns old and new are accommodated. *Lomaria gibba* var. *bella* that was raised here some years ago is distinct and fine, and not less distinct is Messrs. Veitch's new crisped Maidenhair Fern *Adiantum Luddemannianum*. *A. farleyense* and *A. gracillimum* are in capital condition. Other Ferns are worthy of notice, but only one of them can be alluded to—namely, the Sweet-scented Fern, *Asplenium fragrans*. It is to be regretted that this remarkable Fern is not more plentiful. It is of dwarf growth, and has elegant fronds with the perfume of Violets. It is rather a slow-growing Fern and cannot be increased rapidly, otherwise it would be included in all collections. It was brought from Jamaica towards the close of the last century. Its odour is most distinct and agreeable—just the fragrance of Violets but not quite so intense.

In another portion of the grounds are other houses, one of which contains a healthy stock of the valuable conservatory plant *Luculia gratissima* and other cool-house plants. A stove contains Orchids, *Gardenias*, and ornamental-foliaged plants, another large house being filled with *Camellias* and *Azaleas* all in excellent condition. Of the useful *A. amœna* there are many healthy plants, and on the wall of the house out-

side a Camellia has grown without any protection for many years.

Some light well-ventilated structures are employed for growing Vines in pots. Of these there is a considerable number, and finer canes and cleaner foliage it would be difficult to find. Many of the canes are sold. They are stout, short-jointed, and contain those bold eyes which gardeners delight to see. They have been grown by Mr. Fancourt, the present manager of the glass department, and they do him great credit. Figs are also well grown in pots, small bushy plants, Negro Largo being one of the most popular. It is one of the best of Figs, and the demand for it increases yearly. Besides the houses there are several brick pits and all occupied. In the front south wall of one of them the Wall Rue, *Asplenium Rutamuraria*, appears to be naturalised. In this—the frame department—a collection of hardy perennials and alpine plants are grown in pots plunged in ashes ready for safe transport at any time and to any distance.

A collection, evidently a very old one, of hardy border flowers is growing in the grounds—a favourite collection with Mr. Osborn, both on account of its long-established character and the attractiveness of many of the plants. Amongst them *Geranium sylvaticum flore-pleno* was very gay, as were the *Veronica maritima*, *dentata*, *amethystina*, &c. *Hieracium*, *Potentilla* (P. William Rollisson was very fine), *Solidagos*, *Oenotheras*, *Lythrums*, and other plants of this nature were also attractive. There is also a collection of hardy bulbous plants in beds, and the best varieties of Clematises are planted by the sides of the walks and trained up poles.

Fruit tree culture is an important feature of this nursery, and under Mr. Pitman's experienced supervision it is well and extensively carried out. Not more care is exercised in producing healthy well-balanced trees than is given to their correct nomenclature. Peaches, Nectarines, Plums, &c., are well trained, and to all appearance will sustain the reputation of the nursery. Many trees are also grown in pots for fruiting in orchard houses, the demand for these being considerable. These trees—what there are left of them—are clean and sturdy with well-ripened wood.

Ornamental deciduous trees and shrubs are also represented in considerable numbers and in good condition, for if this is an old nursery and contains other notable examples of venerable trees than those above noticed, it contains also fresh young stock appropriate to the demands of the present time. In a word, the nursery is well furnished in the several departments, and is in admirable working order throughout.—VISITOR.

AMESBURY FREE GRAMMAR SCHOOL OF MR. JOHN ROSE.

ON November 19th was observed as the Bicentenary of this school, founded by the gardener to Charles II. and opened on November 19th, 1677, by the Rev. John Shorthose, afterwards rector of Stanton St. Bernard, Wilts. Mr. Rose was gardener at Dorney Court, Bucks, where, on the authority of an oil painting still hanging at Kensington Palace, he is said to have grown and presented to Charles II. the first Pine Apple ripened in England. After this he was gardener to Lord Essex, who sent him to study the gardens at Versailles, and on his return from France he was appointed to St. James's Park Gardens. He was buried at the church of St. Martin-in-the-Fields, September 17th, 1677. A special service was held at 2 p.m. in the parish church, on the south side of which Mr. Rose placed his school by the permission of the ordinary, and many can remember when the door of the transept was called still "The School-door." At this about eighty of the Trustees and scholars past and present assembled to thank God for the liberality of the founder of the school. A most suitable sermon from Heb. xi. 4: "He being dead yet speaketh," was preached by one of the Trustees, the Rev. E. Duke, a lineal descendant of one of the original "beloved and trusty friends" to whom Mr. Rose entrusted the care of his new school, George Duke, Esq., of Lake; and a son of the Rev. E. Duke, who for more than forty years took the greatest interest in Rose's school both as trustee of the property and examiner of the scholars. The service was followed by a dinner given by the Trustees to the foundation scholars, past and present, of the master Mr. E. W. Flower, and by Mr. Sandell to the other present scholars; and nearly fifty of the "old Roses" joined at their own expense. After the toasts "Church and Queen," "The Preacher, with many thanks for his sermon," "Sir E. Antrobus, with thanks for the use of the room," where formerly

Rose's school was held, the Vicar proposed "The Memory of Mr. John Rose," and gave a short sketch of his life mainly taken from the *Journal of Horticulture* for August 5th, 1875. Mr. Rose was gardener at Dorney Court, and afterwards to Lord Essex in the Strand, who sent him to Versailles to study the gardens there. On his return he became gardener to Charles II. at St. James's Park. In 1672 was published "The English Vineyard Vindicated, by John Rose, Gardiner to His Majesty, at his Royal Garden, St. James, formerly Gardener to Her Grace the Duchess of Somerset," which, it appears, Evelyn reduced to writing from Rose's information. Mr. Rose left by will £10 to the poor of Amesbury, money to purchase a set of silver-gilt Communion plate for Amesbury church, which is still in use, though remodelled in 1853, and has just been restored; and an estate at Ditchett to support the school. This was followed by a very interesting paper by one of the Trustees, Mr. Edwards, on the Old Masters (one of whom in 1687 was the Rev. Thomas Naish, some time tutor to Addison), especially Mr. Wm. Cox, who for nearly fifty years "grounded" not only Rose's scholars, but many of the sons of the most respected families in Amesbury and the villages round, in the rudiments of religion and useful learning. Mr. Rooke responded for the Trustees; and the Treasurer, Mr. F. Melsome, proposed "The Health of the present Master, and Prosperity to the School," and after Mr. Flower's reply, "The Old Scholars" was responded to by Mr. Sandell, Mr. Hunt of Pewsey, and Mr. Henry Gane of George Town, Canada, and many interesting stories of old times were told. Mr. Sargent then, on behalf of the Trustees, requested the master to give the boys a holiday the next fine day; and a social chat, under the genial presidency of an "old Rose," with a few songs, and a reading or two at intervals, brought a very pleasant day's proceedings to a close.—(*South Wilts Express*.)

ROYAL HORTICULTURAL SOCIETY.

DECEMBER 4TH.

DURING the year that is now approaching its termination we have had to record a series of excellent meetings; and this, the last of the periodical gatherings of 1877, has proved a successful one. The work done at these meetings is important work. New plants, flowers, and fruits are subjected to close examination, and their characters are determined by competent censors. Many new and valuable plants have been honoured, and examples of special and superior cultivation have been recognised during the year. Fruit has been less plentifully exhibited, yet some new and worthy examples have from time to time been submitted for examination. Vegetables have also been represented, notably collections which have been grown in the Society's garden, with the important object of determining their merits and correcting their nomenclature. The meetings have thus been essentially useful; yet beyond this many of them have been extremely attractive—have been, in fact, exhibitions of considerable extent and of exceptional merit. The chief horticultural establishments have poured forth their treasures, supporting at the same time the Society and sustaining their own fame and reputation; and private cultivators have honoured themselves and the craft to which they belong by the excellence of their produce submitted to these meetings, which afford the best expression of practical horticulture to be found in this country.

FRUIT COMMITTEE.—Henry Webb, Esq., V.P., in the chair. Five very fine Smooth Cayenne Pines were exhibited by Mr. Miller of Coombe Abbey, and which weighed in the aggregate 25 lbs. A cultural commendation was awarded to them. Mr. Miller also exhibited a variety from Pernambuco, which was recognised as that grown in this country as Prince Albert. Mr. Wildsmith, gardener to Lord Eversley at Heckfield exhibited three bunches of Gros Guillaume Grapes, the flavour of which was excellent, and a cultural commendation was awarded. Mr. Atkins, gardener to Col. Lloyd Lindsay, Lockinge Park, Wantage, sent a very fine collection of Grapes. The two bunches of Muscat of Alexandria were the admiration of everyone from the uniformity of the berries and their fine golden colour. The Alicante were also very large and finely finished; and the Black Hamburgs, though not large bunches, were equally well grown. The Committee unanimously recommended a silver medal. Mr. Sidney Ford, gardener to W. E. Hubbard Esq., Leonardslee, Horsham, exhibited two bunches of Mrs. Pince's Grape, one from a Vine grafted on Royal Muscadine and the other on Royal Vineyard. Those grown on Royal Vineyard produced berries that were quite black and partially shrivelled, the flesh very firm and cracking when eaten, and with a considerable briskness of flavour; those from the Royal Muscadine were not thoroughly coloured, the flesh was much more tender, and the flavour very similar to the other. A bunch of Alicante from a Vine grafted on the Raisin de Calabre was also exhibited,

but the fruit in either case did not seem to have been improved by the experiment. Mr. Bennett of Rabley sent a plant in full fruit of Garibaldi Strawberry. Mr. J. Muir, gardener to C. R. M. Talbot, Esq., M.P., Margam Park, South Wales, sent a very rich collection of Oranges, Lemons, &c., consisting of eight varieties. The trees producing these are more than three hundred years old, and they are annually grown out of doors from the middle of May till the middle of October and wintered in houses without any artificial heat. Some of them are now bearing from four hundred to five hundred fruits.

Mr. William King of Horsham Park sent a seedling Apple of good appearance, but it was not superior to other varieties already in cultivation. Mr. Goodacre, gardener to Lord Harrington at Elvaston Castle, sent a showy little Apple which came as a sport on a tree of a variety called Lord Lennox, but which had no merit to recommend it. Mr. G. T. Miles, gardener to Lord Carington, Wycombe Abbey, sent fruit of a new variety of Tomato which is exactly similar to Little Gem of Bliss. A cultural commendation was awarded.

Mr. E. Gilbert, The Gardens, Burghley, sent two brace of Cucumbers of Col. Trevor Clarke's variety of Telegraph. A letter of thanks was awarded; and the same award was made for a brace of Tender-and-True exhibited by J. McIntosh, Esq., Duneevan, Weybridge (Mr. Taylor, gardener); and for a brace of Improved Telegraph sent by Mr. Roberts, gardener to Baron Rothschild, Gunnersbury. Mr. Wildsmith of Heckfield sent specimens of Veitch's Self Protecting Broccoli, and specimens were also exhibited by Messrs. Veitch & Sons. It was awarded a first-class certificate. Messrs. Stuart & Mein of Kelso sent specimens of Mein's Triple-curved Borecole, a very finely curled variety of curled Kale, to which a cultural commendation was awarded. Mr. E. Dean, Ealing, sent specimens of the American Dwarf Purple Top and Orange Jelly Turnips, to which a letter of thanks was awarded. Mr. Chambers, Westlake Nursery, Isleworth, sent a large basket of Blenheim Orange Apples of very excellent quality, for which a similar award was voted.

A very fine collection of Apples remarkable for size and beauty was exhibited by Mr. Sidney Ford, gardener to W. E. Hubbard Esq., Leonardslee, Horsham, to which a silver medal was awarded. Mr. Skinner of Boughton Monchelsea, near Maidstone, sent a fine collection of Apples as grown in his orchards for market purposes. The specimens were very fine, and a silver medal was recommended. Mr. Robert Fenn of Salhamstead sent a good collection of Apples to be named.

FLORAL COMMITTEE.—G. F. Wilson, Esq., F.R.S., in the chair. Messrs. James Veitch & Sons contributed a very choice, varied, and attractive collection of Orchids, including the magnificent *Cattleya exoniensis*, also *Odontoglossum cirrhosum*, O. Rossi majus, and O. madrense; *Saccolabium giganteum* and *S. minutum*, *Oncidium Forbesi* and *purpuratum*, *Cymbidium Mastersi*, *Sophronis grandiflora*, *Calanthes*, *Maedevallia tovarense*, and several *Cypripediums* including *Schlimi*, *Sedeni*, *selligerum*, *vexillarium*, *anathum*, *marmorophyllum*, *Arthurianum*, and *insigne Maulei*. Messrs. Veitch also exhibited healthy and well-flowered plants of *Fuchsia Dominiana*, raised by Mr. Domy thirty years ago by crossing *F. spectabilis* and *F. veratrifolia*. The foliage is a rich dark green, and the flowers bright orange scarlet. It is a valuable plant for winter decoration, and is deserving of extensive cultivation. Small plants admirably grown and well flowered of *Daphne indica rubra* filled the air with fragrance. *Rhododendron Arthur Potts*, coppery orange, was also included in this group; also *Bouvardia leiantha* with small but brightly coloured flowers. *Poinsettia pulcherrima rosea* was also exhibited. The heads were fine, the bracts broad and of a rosy scarlet colour. A vote of thanks was awarded for the collection, and the Committee recommended that a medal be given for *Cattleya exoniensis*.

Mr. William Bull exhibited a very fine collection of new and ornamental plants, including some fine examples of Cycadaceous plants, the new *Anthurium Veitchii*, *Dracæna Goldieana*, the bright old *Impatiens Jerdonæ*; a wonderful spray about a foot in length, and containing twenty flowers, of *Lapageria rubra superba*; *Dracænas*, Ferns, and *Crotons*. First-class certificates were awarded to Mr. Bull for *Cybotium pruinatum*, a fine Tree Fern from the Sandwich Islands, with bold spreading fronds and hirsute stems; also for *Croton picturatus*, a remarkable plant, both grotesque and elegant. The leaves are first almost cordate, terminating in a slender thread, from which is subtended the secondary leaf, which is about half an inch wide, 3 inches long, and slightly spiral. The plant is well coloured, and will be suitable for table decoration. Also to *Geonoma princeps*, a beautiful Palm with dark and elegant fronds. *Tillandsia Lindlei* was noticeable in this group, for which a vote of thanks was awarded.

Mr. Robert Parker exhibited a collection of cut flowers and sprays of hardy shrubs with ornamental berries. This collection was extremely beautiful. Amongst the berry-bearing sprays were *Rosa rubiginosa* and *Cotoneaster Simmondsii*, with flowering sprays of *Berberis Darwinii*, *Arbutus Andrachne*, *Lonicera fragrantissima*, and *Erica cædonodes*. Amongst the

flowers were *Tritomagrandis*, *Aponogeton distachyon*, *Helleborus niger maximus*, very fine; *Megasea (Saxifraga) rubra*, *Gentiana acaulis*, *Tussilago fragrans*, *Mignonette*, *Violets*, and *Pansies*. A plant of *Lapageria rosea superba* had richly coloured flowers, and plumes of *Gynierium argenteum flore-albo* and *G. argenteum flore-roseo* were highly effective. A vote of thanks was awarded.

Mr. Cannell exhibited a box of cut blooms of Zonal Geraniums of remarkable quality. They comprised the varieties to which we alluded last week, and are indispensable for autumn decoration. Some of the flowers exceeded 2 inches in diameter. Also a plant of *White Vesuvius*, a sport from the well-known scarlet variety. The flowers are nearly white and freely produced, and the habit of the plant is compact. A first-class certificate was awarded for this promising variety.

A first-class certificate was awarded to Mr. Turner, Royal Nurseries, Slough, for *Perpetual Carnation Alegatière*. This is a splendid acquisition. The plant is dwarf and sturdy in habit, and the flowers, which are smooth and well formed, are of a glowing crimson-scarlet colour and are produced in great profusion. It is a model market and decorative variety, distinct and of sterling merit.

Mr. Chambers, Westlake Nurseries, Spring Grove, Isleworth, sent plants of *Asplenium viviparum*. It is a very elegant Fern when so well grown as it was here represented. A vote of thanks was awarded.

Mr. Dean sent flowers of climbing *Tropæolum Perfection*. The flowers are well formed and of good substance; they are rich crimson-scarlet with dark veins. It is a very fine variety, and was awarded a first-class certificate.

Mr. Mill, gardener to Lord Rendlesham, Rendlesham Hall, Woodbridge, exhibited a spike of *Oncidium æmulum* with a spike 10 or 12 feet long having a dozen branchlets and eighty flowers. A cultural commendation was awarded, also a vote of thanks to Mr. Mill. Mr. Ollerhead exhibited healthy plants of *Centropogon Luceanus*, proving its value for winter decorative purposes and for affording cut flowers. A vote of thanks was awarded.

Messrs. E. G. Henderson & Son, Pine Apple Nursery, Maida Vale, exhibited plants and cut blooms of *Chrysanthemums*; of the latter a first-class certificate was awarded to Golden Empress of India, the flowers being of good size, incurved, and of a bright primrose colour. Messrs. Jackson & Sons, Kingston, also exhibited *Chrysanthemums*, to one of which—Fulton, Japanese—a first-class certificate was voted. It is an elegant flower of the most brilliant yellow imaginable. *Fulgore*, rosy purple, in the same stand, was also very fine but faded in colour. Mr. Moorman, gardener to the Misses Christy, Coombe Bank, Kingston-on-Thames, exhibited twenty-four Japanese and twelve incurved *Chrysanthemums*, for which a vote of thanks was awarded, and a first-class certificate was awarded to Mr. Moorman for Fulton.

Messrs. W. Paul & Son, Waltham Cross, exhibited examples of the yellow-and-orange-berried Holly, showing the richer colour of the latter; also a very glaucous form of *Picea nobilis*, which is much more handsome than the ordinary type of this Conifer.

A collection of admirably grown plants of the old double *Primula* was sent from the Society's garden at Chiswick. It is a question if this old favourite is surpassed for general usefulness by newer varieties of double *Primulas*.

At the close of the business the then Committees received the thanks of the Council, and the Secretary (Dr. Hogg), was also warmly thanked by the members of the Fruit Committee for his services.

It only remains now to say that all who have been identified with the meetings have discharged their duties willingly and well. Mr. Barron and his assistants appear, one and all, to have exerted themselves in carrying out the wishes of the Council in contributing to the convenience of exhibitors and visitors; and it is only just to say that by the care, activity, and courtesy of the officials the labours of the Committees have been expedited, and the pleasures of all identified with the gatherings have been enhanced. We look back on the passing year with a considerable share of satisfaction, and look forward to the ensuing season with confidence and hope.

THE AMERICAN DODDER (*Cuscuta Cephalanthi*) has long been a pretty and interesting object in the cool greenhouse at Glasnevin, where the little alien was clothing some plant with its pretty pearl necklaces, but it was only the present year it occurred to Dr. Moore to try it out of doors. This he did by attaching it to a plant of *Forsythia suspensa*. The flowers are produced in marvellous profusion in clusters of ten or a dozen at short intervals all along the brown twining stems. Each flower is nearly the size of, and not unlike in shape, that of the Lily of the Valley, and as pleasingly fragrant. Though the frost has destroyed the beauty of the flowers, there is no occasion for apprehension that the Dodder itself will not come safely through the winter, and if permitted to extend itself, clothe a much larger portion of the *Forsythia* with its clustering flowerets next and other years, till ultimately the supporting

plant succumbs to the exhausting operations of this pretty vegetable vampire. The smallest bit of it will grow if attached to any exogenous plant or shrub.—(*Irish Farmers' Gazette*.)

USEFUL GLASS STRUCTURES.

WHERE the soil is dry or can be made so by draining, pits or houses partially below the ground level can be safely formed. They are the most economical of all garden structures, for a maximum amount of heat can be maintained in them by the consumption of a minimum quantity of fuel. In many gardens brick pits are already formed as receptacles for manure over which frames are placed; these are easily converted into low houses, which are far more valuable than frames for propagating and early forcing. It was in considering an existing instance of this kind and seeking to turn the pit to a better purpose that the accompanying sketch was produced.

Fig. 83 shows sections of three houses: A, a snug little lean-to—propagating, Melon, or Cucumber house. B, a semi-

of border flowers. Were I to ask some of those who are interested in herbaceous plants if they were acquainted with *Cimicifuga* there would be a little astonishment at the sound of its name, yet we have such plants in a list published by Linnaeus. They are but a small family and very little known. We are indebted to the North American continent for this little tribe of border flowers. Those who are acquainted with *Actæa spicata* may form an idea what *Cimicifuga* is like. The name is derived from *cimex*, a bug, and *fuga*, to drive away, indicating that the plant is in possession of qualities to expel noxious vermin. If such be the case we ought to have these plants extensively cultivated. We are also told that in North America *Cimicifuga serpentaria* is an antidote against the bite of the rattlesnake.

Our subjects are among the taller-growing plants, and are well adapted for open spaces in the shrubbery as well as the border. They are not particular as to soil. Well-decomposed vegetable matter, sandy loam, and peat, incorporated with the ordinary garden soil, will meet their requirements. They like

Fig. 83.—Combined Section of Propagating Pit, Melon House, and Vinery.

span possessing all the advantages of A with the important additional one of a stage for stove plants and Orchids; or it could be turned to account for a variety of useful purposes, especially the early forcing of Roses, flowering shrubs such as Deutzias, Weigelas, Lilacs, as well as Lily of the Valley and bulbs. This house would also answer admirably for Vines in pots and Kidney Beans. C shows a section of a loftier elevation—a lean-to, forming the most simple style of vinery as well as the most efficient. Sweep away all internal fittings—the stage, the inner wall, the soil and rubble; put plenty of pipes near the floor, not on it, but just elevated a few inches upon pipe stands, so as to turn all the heat to account and let none of it be wasted by absorption into walls and floors, as is too often the case; pierce the front wall and plant Vines in the soil, and I really do not see what more a skilful Vine-grower would require, or what advantage a more elaborate state of things would confer upon a non-skilful one.—EDWARD LUCKHURST.

OUR BORDER FLOWERS—BUGWORTS.

It seems strange that plants which have been among us for more than a lifetime are many of them not to be met with in a day's journey, and are not even known to many cultivators

moisture, and do not object to partial shade, yet will bear full exposure. They continue long in flower, sometimes until the autumn. They are increased by division in the spring.

There are only some four or five species enumerated. *Cimicifuga serpentaria* and *C. racemosa* are the most commonly met with, and that but seldom. *C. palmata* is perhaps the most desirable of the family.—VERITAS.

ANTHURIUM ORNATUM.

THE plant figured is a notable representative of a noble family of ornamental plants. Most of the species are remarkable for their bold coriaceous foliage, while others are attractive by their handsome flowers. The former section are represented by *A. magnifica*, which is so imposing for stove and hall decoration; *A. crystallinum*, than which few plants have more really handsome foliage, velvety in texture, green, and relieved by ivory white veins; *A. regale*, *A. coriaceum*, *A. cordifolium*, and others which are suitable for indoor decoration at any time and for subtropical effect outdoors during the summer months. The flowering section is made familiar by the brilliant and valuable *A. Schertzerianum* and the pearly white *A. S. Williamsi*. The foliage of these is neat rather

than imposing, but *A. ornatum* has both striking foliage and attractive flowers. This distinct Anthurium is being distributed by Mr. B. S. Williams, who states that in well-grown plants the petioles are about 3 feet long; leaves light green and cordate in shape, from 9 to 12 inches broad, slightly veined with white. The flowers are thrown well above the foliage on stout flower stalks; the spathe, which is pure white, is from

copious supplies of water during the growing season, are the chief essentials to success.

NEW BOOK AND NEW EDITION.

Two new volumes are before us, one small the other large; one to a great extent speculative, the other wholly practical.

Fig. 84.—ANTHURIUM ORNATUM.

6 to 8 inches in length and $2\frac{1}{2}$ in breadth, tapering towards the apex; the spadix, which is about 6 inches in length, stands up very conspicuously, being nearly black, but covered with a violet hue slightly dotted with white.

Anthuriums are of easy culture. Moderate stove heat, great cleanliness of the foliage, very free drainage, and a very rough and open compost of turfy loam, peat, and charcoal, with

We will first refer to the smaller one. It is entitled "*Multum-in-parvo Gardening*," and is published by Crosby, Lockwood, and Co., Ludgate Hill. The object of the author (Samuel Wood) is to show (I) "How to make one acre of land without glass produce by the cultivation of fruits and vegetables £630 per annum clear profit." II. "How to grow flowers in three glass houses so as to realise £176 per annum clear profit."

As if conscious of the startling nature of his proposition, also of the incredulity of the public, the author "fancies some readers laughing at the idea." We rather fancy so too; it is an "idea" of a class to provoke a smile. Yet with that characteristic confidence which figures inspire, Mr. Wood has no doubt of his ability to prove satisfactorily that the handsome sums named can be realised. We do not share the author's confidence in the plan projected, which in Section I. is briefly as follows:—

A series of brick walls are to be built 4 feet high, with a border 4 feet wide on the south side, curbed round with two courses of brickwork, and at the front of the border a path is to be made 2 feet wide. This work "is to be" done by the acre, for we are not told that it has been done. Estimates (too low) are given of the cost of the walls, and the mode of carrying out the "idea" is detailed. On the south side of the walls Peaches, Nectarines, and Apricots are to be planted "about 5 feet apart," and two Tomato plants are to be grown "between each of the trees." Don't smile, gardeners, for recollect this is *multum in parvo* gardening. The reason why Tomatoes are to be so grown is stated to be the "obvious" one that "they cannot be grown without walls or glass." If the author had taken a trip into some of the market gardens near London last summer it would have been equally "obvious" to him that they can be and were grown and ripened "by the acre" in open fields, and we could point, too, to a garden as far north as Lincolnshire where they are successfully grown in a similar manner. We predict that they will be grown on this "impossible" plan much more generally than the new "idea" promulgated in the book will be adopted.

The north sides of the walls are to be covered with Red Currants, the trees to be planted in a border 9 inches wide, which border is also to contain a row of Strawberries which should produce "an average of two hundred fruit per plant"—*multum in parvo* again; or Auricula seed is to be grown instead of Strawberries, and if the seed is of a very superior strain it may be sold for 5s. per ounce, unless "some difficulty should arise in disposing of it," on which account Strawberries are given the preference as they "always sell."

The south borders are to be cropped with early Potatoes and Radishes, which are, perhaps, the most reliable of all the crops recommended, to be followed by Dwarf Kidney Beans, and probably (although that is not stated) by red spider for the Peach trees. Adventitious crops, such as Lettuces, are mentioned, but they are not relied on, as a nett profit of £624 5s. 9d. per acre can be obtained without them. The amount received, after deducting £129 4s. 3d., is accounted for as follows:—

Peaches, Nectarines, and Apricots.....	£330	0	0
Red Currants.....	70	0	0
Tomatoes.....	50	0	0
Radishes.....	156	0	0
Early Potatoes.....	50	0	0
Dwarf Beans.....	58	10	0
Strawberries.....	39	0	0
Total.....	753	10	0
Annual expenditure.....	129	4	3
Nett profit.....	624	5	9

"It is astonishing," adds the author, "what can be done with one acre of land." It is, and we shall be astonished to hear that Mr. Wood has done what he has represented as being so easy of attainment, and the more astonished if it is an average (and it is no use without) of a series of years. The crops mainly relied on, and which involve the greatest outlay in preparations—namely, Peaches, Nectarines, and Apricots, are notoriously uncertain when glass is not afforded them. We have inspected many gardens in different counties during the present year, and notwithstanding that those gardens are under thoroughly competent men, we have deplored with the disappointed managers the failures of the crops mentioned from causes wholly beyond their control. Neither has the year in this respect been particularly exceptional; many similar failures have preceded the dearth of tender stone fruits of the present year, and many more will follow where the trees are exposed. We do not hesitate to say that there are far more blanks than prizes in growing the fruits in question on exposed walls. Shall we, therefore, ignore the teachings of long and dearly bought experience, supported by evidence that in its nature is incontrovertible, in favour of a speculative theory—an "idea?" Notwithstanding the author's confidence in his argumentative ability we continue to indulge in "incredulous smiles." We regard his premises unsound, his logic faulty, and his figures fallacious.

The second part of the book, that relating to the profitable culture of greenhouse plants, consists of only half a dozen pages, which we will dispose of in little more than half a dozen lines. Market plants can be grown profitably by those who have been trained to the trade, and a man, even if he is a good general gardener, may easily invest money in a calling with which he may feel himself familiar, and lose it. We agree that the cultivation of greenhouse plants by competent men is "an agreeable mode of getting a living *supposing*" (the italics are ours) "he is so situated to sell all off as the things come on."

The book also contains an appendix, with nothing noteworthy in it, about insects. It reveals also the cause of the Potato disease—namely, "atmospheric influences" in the form of "sulphureted hydrogen," which communicates the disease to the plants. As evidence of the power of the "atmosphere" on Potatoes we cannot resist quoting the concluding lines of this sensational book at the risk of provoking further "smiles:—"

"The atmosphere seems to affect this plant for good or bad more than it does any other vegetable. I had it once stated to me by an old man whose word I have no reason to doubt that upon one occasion he was in Newfoundland, being one of a ship's crew, when the master set them to plant some Potatoes in his garden, and which were of a white kind, brought out from England. They stayed there until they were ready to dig up, and when this was done they all turned out to be red ones. This proves that the Potato is very easily affected by the atmosphere."

We should not have noticed this book so fully had we not felt that its tone is misleading, and that caution is necessary in putting the author's "idea" into practice.

Our notice on the larger and better book alluded to above—Thompson's "Gardener's Assistant"—must be deferred. We can only say now that it is a sound and splendid work.

NOTES AND GLEANINGS.

DURING November, at Ticehurst in Sussex, just 9 inches of RAIN FELL! The highest temperature was 59° and the lowest 30°. Rain fell on twenty-six days.

A CORRESPONDENT "Q.," writing to us on ZINC LABELS FOR ROSES states—"I have many failures every year, and numbers of dead branches have to be cut away. I am disposed to think that possibly the zinc being fastened on with copper (causing galvanic action), may have something to do with it. The opinions of other rosarians will oblige."

THERE is always something worthy of note in LORD LONDESBOROUGH'S celebrated garden at Norbiton. At the present time several Orchids are attractive, especially *Oncidium Londesboroughianum*, which was not long ago awarded a first-class certificate; it is remarkable on account of its fine and richly-marked sepals and petals. *Cattleya exoniensis* is also flowering and is extremely beautiful, as also are *C. El Dorado splendens*, *C. labiata* and *C. labiata Pescatorei*; also *C. marginata* and *C. marginata prastans*, the last-named being especially fine. *Vanda cœrulea* continues producing a fine display, and several varieties of *Oncidium varicosum* and *Odontoglossum triumphans* are flowering freely; noticeable also are *Masdevallia tovarensis*, white, and *M. Davisii*, bright yellow. Less aristocratic but not less useful is a houseful of the old white *Geranium Madame Vaucher*; the plants are flowering with great freedom and the colour is very pure. Similarly valuable is a stock of robust young plants of *Miss Marshall Fuchsia*, the plants being covered with fine flowers. A houseful of *Heliotropes*, the "old sort," tells at a glance how useful this plant is for affording a supply of flowers, which are always valued during the winter on account of their refreshing perfume. The plants are grown in 48-sized pots. On another occasion Mr. Denning's mode of growing *Eucharis amazonica* may be noticed.

EARLY POTATOES.—Earliness alone considered, the old Ash-leaf Potato is not yet surpassed. It is also very dwarf, and therefore easily covered. Myatt's Prolific and Veitch's Improved Ashleaf yield double the weight of crop, but are ten days or a fortnight later than the first named. There is not much gained by planting earlier than the middle or end of February, and even then only in dry and sheltered positions. The sets should be placed on end at once in a light cellar or shed secure from frost, and they will make strong sturdy shoots before planting.—WILLIAM TAYLOR.

A VERY good proof of the MILD AUTUMN, writes a Fulham correspondent, is shown here by the common Primrose, which

has been flowering since the commencement of November as freely as it usually does in March, and presents quite a gay appearance. *Limnanthes Douglasii* is in full flower, also *Mignonette* is flowering as freely as in July, but it is not quite so highly scented as during the summer.

— Among cut flowers few are more valuable than the CAPE JASMINES (*Gardenias*), one of the most useful of which is *G. florida*. The best way of producing the finest flowers in the greatest number is by having the plants planted out in a well-heated pit. In this way thousands of flowers are cut by Mr. Denning at Norbiton, Mr. Jones at Windsor, and others who have great demands for white flowers of the first quality. In growing *Gardenias* brisk heat and copious supplies of water are of greater importance than soil. We have seen the plants luxuriating in turfy loam, in pure peat, and in a compost in which leaf soil preponderated. A mixture of the three kinds of soil named, with top-dressing of manure, will grow the plants well provided the first essential—water—is applied regularly and freely to roots and foliage. Given this and a sufficiently high temperature, luxuriant foliage and splendid flowers will be produced, and no mealy bug, that inveterate pest of gardeners and *Gardenias*, will be seen on the plants.

— WE extract the following glowing account of *KENTIA MACROCARPA* from the *Irish Farmers' Gazette*.—This new and very rare Palm (the specimen in the Glasnevin collection and one or two more being, perhaps, its only representatives in cultivation), is one of the noblest and most striking of the pinnate-leaved section of the family. The dark olive-green of the stem and fronds is very peculiar, and still more so the fiery tints of the undeveloped frond, which gives it the aspect of a great jet of flame rushing up from the centre of the stem. Just at the present moment the Glasnevin plant is in the condition to show this remarkable feature to perfection.

— LARGE consignments of FOREIGN GRAPES have been recently received by the London fruiterers. Almerian Grapes have been selling at 8d. per lb., and Black Hamburgs at 10d. The white Almerian Grapes are as large as Black Aliantes, and are greenish white in colour. Their flesh is crackling, and their juice refreshing. The Black Hamburgs have been thinned and the berries are of good size. These Grapes are packed in corkdust, which is coarser than sawdust, light and dry. When the bunches are removed from the boxes the corkdust falls from amongst the berries, scarcely a particle adhering to them, and the bloom is only very slightly rubbed. Corkdust is evidently a capital packing material for Grapes.

— WE have received from the Hon. and Rev. J. T. Boscawen a fine flower of *LAPAGERIA ROSEA* which was gathered out of doors on the morning of the 3rd inst. from a plant 25 feet high; this is the more noteworthy since Mr. Boscawen informs us that 8° of frost were registered the same morning in his garden at Lamorran.

— MR. D. F. MCKENZIE, forester, Murthley Castle, writing in the "Journal of Forestry" on the TIMBER TREES OF THE FUTURE, predicts that *Abies Douglasii* will sooner or later take the place of our Larch, and *Abies Menziesii* that of our other Pines. The timber of *A. Douglasii* is as durable as Larch when in contact with the soil as a fence or other post or stob, it being in most cases equally full of resin. It is also much prettier for decorative work and house carpentry. Roofs on the Gothic principle, such as the famous roof over Westminster Hall, London, if done with the wood of the Douglas Fir, could not for beauty be excelled even by the best Oak, as it has naturally a rich mellow colour when of large dimensions. It also lacks the bad qualities of the Larch, as it does not twist or warp, and is not, so far as has yet been ascertained, liable to any disease in this country, while it produces nearly double the bulk of timber in a given time. *Abies Menziesii* is also a rapid-growing timber tree of large dimensions, and its fibre is more elastic and tenacious than Fir or Norway Spruce.

— SOME one inquires how far north the ENGLISH WALNUT will mature its fruit. Mr. Robert Coit has this tree in his garden at New London, Conn., which bears and ripens nuts every year. This year the crop is larger than ever. The tree is at least twenty-five years old, and has been in bearing some eight years. It is sheltered on the north and west by buildings; but in the garden adjoining is another English Walnut tree exposed in all directions. It is an old tree, and has ripened crops of nuts more or less sparsely for twenty years. The latitude of New London is 47° 21' north.

— PROFESSOR ELBRIDGE GALE of the State Agricultural College, Manhattan, Kan., has written as follows on TREES:—

Nothing else can bind families to their homes like trees. We watch their growth from day to day. They are linked in memory often with the bright and sweet things of the past. We learn to love them and to love their history. The ordinary products of the farm soon ripen and are gone, but here Nature slowly unfolds her purposes, requiring patient waiting and constant care for many years: hence men learn to love these trees. They give a peculiar charm in the eyes of the owner to the picture of the home. The farm crops, as a rule, hold the family only from spring to fall, and the owners of stock may roam, like their herds, from hill to hill or from county to county; but he who plants trees finds himself by the strongest possible ties—both of interest and affection—bound to the soil.

NOTES ON VILLA AND SUBURBAN GARDENING.

THE leaves have fallen from the Oak and Beech trees, which generally retain them the longest. We never remember their being cleared so quickly before. The aspect is dreary, and reminds us that winter is close at hand; but the weather continues very open, which is an advantage to all who have alterations in progress. Planting and groundwork generally should be prosecuted with all possible dispatch, for at any time now the ground may be covered with snow, or frost may set in so severe as to prevent further operations being conducted. Clear the fallen leaves from lawns and lightly dig the borders between shrubs, burying all stray leaves to prevent them being blown about all the winter and to give a freshness and tidiness to the garden.

Seakale and Rhubarb may now be lifted from the open ground and placed in heat for an early supply, or the roots may remain in the ground and be covered with pots or boxes, with a sufficient thickness of leaves placed over them to generate a moderate heat, and both Kale and Rhubarb will be ready for use in a few weeks. If the method of lifting the roots is preferred a Mushroom house is an excellent place for forcing them, but any place is suitable for the purpose where there is a genial warmth. Care must be taken to exclude all light from Seakale, otherwise it will be of a purplish hue and useless for table. Endive also blanches well in a Mushroom house, and a few plants lifted as required and placed in the house will in a short time become beautifully white.

Should dull weather continue or frosty nights set in, a little fire heat to exclude both damp and frost will be absolutely necessary both in the greenhouse and conservatory. As there are not many flowers to be had out of doors now it becomes all the more necessary to cherish those which can be had within. *Chrysanthemums*, with the exception of a few of the late-blooming Japanese varieties, will be soon past their best; as they go out of flower cut down the old stems and place the pots close together in a cool house or frame, to cause sturdy cuttings to spring up from the base of the plants. The *Chrysanthemums* may be succeeded by *Camellias*, *Acacias*, autumn-flowering Heaths, such as *Erica hyemalis* and *gracilis*, *Cytisuses*, *Coronillas*, *Eupatoriums*, *Bouvardias*, *Primulas*, and early *Cinerarias*; while with the help of a small stove or forcing pit a constant supply of *Azaleas*—*A. amens* and the large single White are especially adapted for forcing early—*Deutzias*, *Dielytras*, *Lilacs*, *Spiræa* (*Astilbe*) *japonica*, *Richardias*, *Rhododendrons*, bulbs, &c., can be readily furnished. A night temperature ranging from 50° to 55° and 60° will be found to bring these along more satisfactorily than a much stronger heat. *Camellias* coming into flower will, if well rooted, be benefited by occasional applications of weak liquid manure. The complaints we frequently hear of *Camellias* shedding their flower buds chiefly arise from improper watering; the plants are often permitted to become too dry and injury follows. Occasionally the dropping of the buds occurs from the opposite extreme—stagnant soil; but if the drainage is good they are likely to suffer more from insufficiency of water than from over-abundance. The leaves should be sponged and kept clean and glossy.

Bedding plants must be examined periodically and have all the decayed leaves removed, or they may cause the plants to damp off. All watering of these and other greenhouse plants should be done at this season early in the morning; by that practice there is the better chance of the surplus moisture drying up before night. *Calceolarias* which are intended for specimens must not be allowed to become pot-bound, but must have larger pots before the roots become matted. Well-drained pots and rich but light sandy soil are necessary to promote luxuriance. These plants and *Cinerarias* may be kept in cold frames if well protected; for although they will flourish in a very low temperature they are very susceptible to injury by frost, especially the *Cinerarias*.

Schizostylis coccinea is a valuable plant for indoor decoration at this dull season of the year; its abundant supply of rich scarlet *Gladiolus*-like blossoms is exceedingly attractive. Plants may be increased by dividing the roots in spring, planting them in the open ground, and potting them again in the autumn.

when the flower spikes commence showing. They remain gay until the end of the year, and well reward for any cultural attention that has been bestowed on them.—J. W. MOORMAN.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

KITCHEN GARDEN.

Our own work in this department is in a forward condition. Digging and trenching, mulching borders, and protecting crops and plants with rough litter when necessary, must be seen to without delay. Where wheeling has to be done it will be necessary to lay light planks on the alleys and paths, unless the ground is hard with frost. So far there has not been sufficient frost to render the surface crisp and clean.

At any time when the ground is saturated with wet and in a too sloppy condition to be dug or trenched with advantage, the corner where the various heaps of manure and vegetable soil are kept may be made neat by turning the heaps over; the vegetable refuse-heap is too often in a very untidy condition. The kitchen boy carries all his trimmings of vegetables there; herbaceous and bedding plants from the flower garden, decayed Pea haulm, stumps of Cabbages, Cauliflowers, &c., are tumbled down in a disorderly manner. In turning over this heap the outer portion that has made little progress in decay should be turned into the centre and the bottom of the heap be brought to the top. Where manure is scarce and leaves plentiful a quantity of the latter may be mixed with the refuse of the kitchen garden. A valuable heap may be formed in this way, and could a few hundred gallons of the drainings from a farmyard be thrown over it occasionally its manurial properties may be much increased, and it may also cause the organic matter to decay more rapidly.

Where forced vegetables are in demand preparations must now be made to start them in the way best adapted to the circumstances of the place. We have tried many different ways to obtain an equable lasting heat, but that of forming a bed of leaves and stable manure is the best, and where each can be obtained on the place the most economical, as the bed forms excellent manure when it has served its purpose as a hotbed. *Asparagus* may be forced in pits or common garden frames. The way we do is to throw an equal quantity of leaves and manure together in a heap, and turn it over about twice in a period of ten days or more to throw off the rank steam, when it may be thrown into the pit or be built into a bed for a frame. If the heat is rather strong it is a good plan to lay some turf over the surface with the grass side down, and on this plant the *Asparagus* in fine soil as thickly as the roots can be placed together. *Seakale* and *Rhubarb* may be forced in various ways, and those who possess a Mushroom house will be able to produce a regular supply from that structure. The roots may be planted thickly in a bed on the ground. Bottom heat is not necessary, the crowns will start regularly and strongly in a temperature of 55°. We grow ours either in the vineries or some other forcing houses. The *Seakale* roots are placed in 12-inch pots thickly together and another empty pot of the same size is placed over it, the drainage holes being stopped to exclude light. We manage the *Rhubarb* well by placing the roots at the bottom of flour barrels, which can be readily obtained here. We either place a lid on the top or throw a cloth over it to exclude light.

Dwarf Kidney Beans may also be sown, and perhaps the best way is to sow thickly in boxes, and when the seed leaves are fully developed to pot the plants off five or seven in 7 or 8-inch pots, using good loam four parts to one of decayed manure. A temperature of 60° at night suits the plants well, and they ought to be placed near the glass.

MUSHROOM HOUSE.

Some few weeks ago instructions were given as to the making-up and spawning of the beds. Keep a moist equable temperature of 55°; in mild weather this may be increased to 60°, but it ought always to be borne in mind that if this temperature is obtained by too much heat in the flue or hot-water pipes without corresponding moisture by evaporation, any Mushrooms that may be produced under such conditions will be small and leathery in texture, scarcely worth the trouble of gathering. Under the right conditions, with moisture produced from walls and paths (not by steaming from hot pipes), the Mushrooms will be formed under conditions most conducive to their perfect development. To arrest evaporation from the surface of the bed it is a good plan to place a layer of clean oat straw on the surface. It ought to be laid on lightly, and the produce of the beds can be gathered by lifting it up gently with one hand or a stick, while the other is used in gathering. The bed must be watered when it is dry, not otherwise. A little experience is necessary to judge of the proper state the bed ought to be in when it is watered; but it is better to err on the side of dryness than to overwater, as the spawn and incipient Mushrooms decay in a wet bed. The water should

be applied through a fine rose water pot, and the temperature of the water should be about 85°. An experienced cultivator can tell when a bed requires water without rooting with his hand into the bed, and by merely putting his head into the house in the morning he can also say whether the atmospheric moisture and heat is right, and the sooner the tyro attains to this degree of intelligence the better. Sometimes beds will continue bearing for a long period, at others a large crop is produced and exhaustion follows, and when a bed has ceased bearing it is best to clear it out and make another. To keep up a certain supply of good Mushrooms it is necessary to have three beds in different stages, made up at intervals of three or four weeks.

VINERIES.

The unfavourable weather alluded to a fortnight ago has not improved, and great care has been necessary to prevent the skin of the berries from decaying. We have not yet removed all the leaves, nor do we care to do so as long as they hold firmly to the stem. It has been necessary to frequently examine the bunches and remove the injured berries.

We start one of the early houses this week. Everything has been ready for this since October. We now water the borders inside and out with tepid water. The outside border has been covered with shutters to throw off the rains. After watering we mulch the surface of the borders with decayed manure. Very little artificial heat is applied during the first two weeks, only enough to keep the temperature to 45°, rising to 50° about eighteen days after watering the borders.

Vines in pots started in October will now be making growth, and the temperature of the house may range about 60° as a minimum. We still hold under all circumstances that it is best not to syringe the Vines after all the growths have fairly started. Previous to this we dew the wood over once or twice a-day to moisten the bark and cause a regular break of the buds. It will depend upon the growth of the Vines as to whether any pressure may be put upon them by maintaining a higher temperature. If the growths are strong and root-action has commenced, and the fruit is required as early as possible, then the temperature may be 65° at night, and this ought not to be exceeded until the bunches are in flower, when it may be 70°, or between 65° and 70° while the berries are setting. Black Hamburg and Foster's White Seedling are the best Vines to grow to produce fruit in pots, but if a large quantity is grown we would have six of the Hamburg to one of Foster's. See that the pots do not suffer from want of water. A large supply is wanted when the Vines are in full growth.

ORCHID HOUSES.

The utility of Orchids in furnishing a supply of beautiful flowers at this season of the year becomes more apparent as Christmas draws near and *Chrysanthemums* show signs of fading. Orchids last long in beauty if the atmosphere of the houses is not kept too moist. An over-moist atmosphere, either at midsummer or midwinter, will cause the flowers to spot and decay before they have reached their prime, but a little discretion in the use of the water pot will prevent this. We have *Dendrobium nobile* in flower, and other plants of it in bud. This is one of the most useful as well as easily grown of Orchids. We have one large plant which annually produces from two hundred to five hundred flowers each year about Christmas, and no plant requires less attention; it has not been repotted for six years or more. The pot is about 18 inches in diameter, and every part of the compost is interlaced with active roots. The plant is kept in heat until June, when it is placed in a vinery from which the Grapes have been cut, and in July it is turned out of doors for a couple of months, no water being given to it nor any rain allowed to saturate the roots; a gentle shower just to moisten the foliage and surface of the pot does no harm.

Calanthes are as beautiful as ever. Unlike some Orchids they do not rest for a season if they have flowered profusely the previous one; but every year the number of spikes increase in a double ratio. *C. Turneri* should be in every collection, as it comes into bloom when *C. vestita* and *C. Veitchi* are over. The decaying leaves of these plants are unsightly and should be removed if possible. Ours are hid by the thicket formed by the arching fronds of *Maidenhair Ferns*. The *Odontoglossum grande* and *O. Insleyi leopardinum* are now in full beauty, and though not so useful in the way of cut flowers as some others, nevertheless they form a striking feature in the cool house. *O. crispum* (Alexandre) is also as valuable for cutting as for forming a pleasing feature in the house; in contrast to it the distinct and noble *Masdevallia Veitchi* is very fine. It may well divide the honours with *M. Harryana*, as being the finest in the genus. The former has the advantage over its rival that specimens may be had in flower both at midwinter and in the dog days; we have them flowering at both seasons from the same importation.

Some growers are recommending a higher temperature for cool Orchids, notably for *O. crispum* and allied species. We find they succeed well with a night temperature of from 45° to 50°. The *Cattleya* house is kept at from 50° to 55°, which is

also lower by 5° than many persons grow their Cattleyas. The East Indian house is best kept at 65°. We sometimes have it fall to 60° in cold nights, and this is better than driving the furnace to keep it up to the highest figure. We have been washing the wood and glasswork of the houses to let in all the light. This is a most important matter, as if the foliage is not fully exposed to all the light possible in winter some of the plants will not flower freely. We have also examined all the leaves and pseudobulbs for scale, thrips, and other insect pests. An invasion of a small species of snail has also caused us much trouble. It eats the young rootlets as fast as they are formed, and very much weakens the plants from this cause. With the aid of a bull's-eye lantern the snails can be found feeding at night.—J. DOUGLAS.

TO CORRESPONDENTS.

* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOUVARDIA CULTURE (C. J. F.).—We cannot account for the reference and omission.

NAME OF ORCHID (A. H. S.).—*Cattleya Loddigesii* var. *Harrisonii*.

EARLY POTATOES (P. S.).—See the remarks of Mr. W. Taylor in another column.

SCALE ON APPLE-TREE SHOOTS (Capt. P.).—It is a species of coccus or scale insect. Brushing over the shoots with a thick mixture of soft soap, sulphur, and water is an effectual remedy.

CLEMATIS AND THEIR PROPAGATION (Hortus).—See notes by Mr. Luckhurst on page 434.

WINTERING PEACH TREES—PRUNING TEA ROSES IN POTS (Puddle).—If the district is a dry one the trees do not suffer if the pots are plunged over the rim in some light material. They could be kept in the greenhouse if you merely have sufficient heat to keep the frost out, and probably that would be the best advice to give. By no means place any of them in the cellar. Prune the Roses now if you want them to flower early. If it is intended that they should flower late, prune in February.

TREES FOR PEACH AND ORCHARD HOUSES (Cherry Pie).—The best for Peach house are Hale's Early, Early York, Royal George, Grosse Mignonne, Walburtion Admirable. Nectarines Lord Napier, Violette Hative, Pine Apple, and Victoria. It is best to plant the orchard-house trees out, that is if you grow only Peaches and Nectarines. Pears and Plums do best in pots. We advise you to try all the trees in pots to begin with. Cherries and Apricots do not succeed with the others. They require a drier atmosphere and more air, but you might try a few of each. The trees will be small to begin with, but we would not have more than about fifty of them, and our choice would be—*Peaches*: One Belegarde, two Crawford's Early, one Dr. Hogg, two Early York, three Hale's Early, three Grosse Mignonne, three Royal George, and one Walburtion Admirable. *Nectarines*: Two Elruge, two Lord Napier, two Stanwick Elruge, three Pine Apple, two Violette Hative, and three Victoria. *Pears*: 1, Beurré d'Amélie, one Beurré Bachelier, one Beurré Hardy, one Beurré de l'Assomption, two Louise Bonne of Jersey, two Souvenir du Congrès, and two Williams' Bon Chrétien. *Plums*: One Jefferson, one Transparent Gage, one Coc's Golden Drop, one Kurke's, one Green Gage. *Cherries*: One Black Tartarian, one Bigarreau Napoleon, one Early Rivers. *Apricots*: Moorpark and Peach.

THRIPS (G. Y.).—Fumigate with tobacco smoke, and dust the plants with Scotch snuff. Repeat the treatment until the insect ceases to appear.

WATERCRESS CULTURE (Miss E. H.).—We know of no work on the subject. Directions for its culture in a border is in this Journal, No. 789 and No. 654.

BEST SIX VIOLETS AND TWENTY-FOUR LARGE-FLOWERED CHRYSANTHEMUMS (R. H. A.).—*Six Violets*: Neapolitan, Russian, Giant, London Blue, Czar, and Victoria Regina. *Twenty-four Chrysanthemums*: Mrs. Rundle, White Globe, Beverly, Empress of India, George Glenny, Mrs. Dixon, Princess Teck, Cherub, Prince Alfred, Princess of Wales, Prince of Wales, Eve, Lord Derby, Pink Perfection, Le Grand, Nil Desperandum, John Salter, Lady Harlinge, Her Majesty, Aurea Multiflora, Jardin des Plantes, Hero of Stoke Newington, Venus, and White Venus.

TREATMENT OF LILIUM LANCIFOLIUM (Inquirer).—Pot them now and plunge the pots in your garden frame. They do not succeed well in ordinary garden soil. If you could obtain some turfy peat or turfy loam in which to plant them they do well if planted-out in the open ground now; if you have not this convenience turn them carefully out of the pots and plant in May.

MANURING (Sambro).—Manure applied to Rose trees is apt to cause excessive growth and few flowers. This effect is not produced on Carnations. Manure is needed to both Roses and Carnations if the soil is poor.

CUTTINGS OF EVERGREENS (Glossop).—Nearly all evergreens may be struck from cuttings, but many of them require to be inserted in sand under hand-lights, especially Hollies and Eucynomus. Cuttings of Laurels, Yews, Aucubas, Laurustinus, and Mahonias will strike, but not quickly, if inserted in sandy soil in a shaded border in the autumn. You might try them now, selecting well-ripened short-jointed shoots about 6 inches long with a little of last year's wood at the base of each. Insert them firmly and rather closely in rows a foot apart, and there let them remain for two years. The price of the book you name is, we think, 3s. 6d.

POTTING EPACRIS AND APHELEXES (A Reader).—After the flowering

sprays have been removed and fresh growth has fairly commenced in the spring, is the time for repotting these plants. Drain the pots well and pot firmly.

CELEBY (Wolverhampton).—Cole's Superb, there are red and white varieties of it.

GRAPES NOT SWELLING (Bay Leaf).—If the Vines planted three years have made good growth and produced a fair crop of fruit this year, we do not see that the fact of there being a rain-water cistern beneath the border has anything to do with the fruit not swelling. Three reasons may be given for undersized berries—insufficient thinning, want of water, a sudden and continuous reduction of temperature just as the fruit is commencing swelling. As to manure water poured upon the border soaking into the cistern and making its water foul, we can only advise you to pump out the water and thoroughly cover the interior of the cistern with Portland cement. If the "manure water passed through the soil nearly as strong as when poured on the border," it simply proves that the border was much too dry when the liquid was applied, and that we suspect is the real cause of the Grapes not swelling.

PLANTING A VINERY (Inquirer).—Your selection of sorts is a good one, but you have too many. A house 33 feet long will contain eleven Vines planted 3 feet apart, each Vine having a single rod trained-up under the roof, the entire area of which would thus be taken up, so that Vines in pots beneath them would be always in shade. If, therefore, you have such Vines, reduce the number planted-out to six, planting them 5 feet apart so as to admit light between them to the Vines in pots. Much better would it be to have eleven permanent Vines, and to have none at all in pots except for the first year, when you might train some fruiting canes between the permanent rods, also on the back wall.

NAMES OF FRUITS (B. A. H.).—No Apples have arrived. (C. R. S.).—Passee Colmar. (Alfred Goodman).—1, Hawthornden; 2, Damelow's Seedling; 3, Golden Requette; 4, Blenheim Pippin.

NAMES OF PLANTS (J. L.).—It is not a Maple, but *Eucynomus europæus*. (B. C.).—Specimens all smashed. It would occupy a page to detail colour-mixing.

POULTRY, BEE, AND PIGEON CHRONICLE.

BIRMINGHAM POULTRY SHOW.

MOTHER BIRMINGHAM once again reminds us that Christmas approaches, and it would indeed be "a gap in our great feast" if we lost our entertainment at Bingley Hall. Last year, in consequence of the decision of the Smithfield Club not to receive cattle from the Midland Counties Show, the Committee decided to follow the Show at the Agricultural Hall in lieu of preceding it; but this did not improve the fortunes of the Show by either an increase of visitors or exhibitors, and this year the Management have elected, and we think wisely, to return to their old dates, and we trust the result will prove satisfactory.

Brahmas, Dark.—The old Dark cock class we thought an improvement on the Palace. The cup bird was a grand specimen, beautiful in colour, with a good head, pretty comb, and legs well feathered but a little too long, and we fancied rather weak, as he did not stand well. Second (same owner), fine-looking, not so richly striped in the saddle as the first, and we thought a little hooked; third coarse in comb; fourth a nice specimen. **Cockerels.**—First a pretty bird of good colour and markings, and neat in head; second deserving his position; fourth, the Aquarium and Alexandra Palace winner, very much out of condition and looked distressed from hard work. Hens.—We thought the position of the first and fourth should have been transposed. The first was well shaped and prettily pencilled, but had a rusty appearance; second better in colour; third attractively pencilled, but for size and general points we preferred the fourth. The pullets disappointed us greatly. We liked the second better than the first, the latter being small and not well pencilled to the throat. The second much resembled the Aquarium winner. The third conspicuous for the same defect as the first. The remainder a very average lot. **Light Cocks.**—Cup bird rather slight in frame but good in colour with the exception of tail; second stouter but not so pure in colour; third a good bird that might have been higher. **Cockerels.**—First (Mr. Haines), in good condition; second a fine specimen but deficient in markings and white in tail; fourth better in colour than the third. **Hens.**—First a grand hen; second also a good bird, but we fancied we discovered a little of the American in the shape of her body; third and fourth in their proper position. **Pullets.**—First a well-grown and prettily-marked pullet; second a good bird; third, the Crystal Palace winner we think, but fairly beaten at Birmingham.

Dorkings are on the whole a good lot, though hardly equal to the Crystal Palace Show. First in old Dark cocks is Mrs. Arkwright with such a bird as has often before appeared here from her yards; he is fine all round and in splendid condition, his comb a little over. Second is not a large bird, and is very white in tail and lobes; third darker. In cockerels the cup bird is good all round, not very striking but with good white feet; second a well-shaped cockerel with good comb but scurfy legs; third a poor bird with crooked toes, in colour a curious mixture of silver and brown; fourth moderately good, with white earlobes; fifth we liked though he has a crooked toe, his comb is fine. Several birds which we thought nearly the best in the class only received highly commendeds, or no notice, among them 403 (Drewry), 404 (White), and 421 (Cresswell) a very fine

bird. The first hen is very fine, but has a bad bumble foot; second has a fifth toe badly swollen, and a prick comb; third very large, of the old-fashioned lighter colour. The class for pullets contains many good birds; Mr. Burnell's cup winner is capital all round; Mrs. Arkwright's second about the largest in the class and highly matured; third a Palace winner, also first at Ipswich we think. Silver-Greys.—Mr. Burnell's Palace cup cock again scores a well-earned victory; second a nice cock with white feet. In cockerels we considered the first-prize one deserving of his honours; he is good in every point. Second was an inexplicable award; the bird is long-legged and stilty, with a lopping comb and several inches of white in his sickles; third a nice cockerel, but again too long on the leg. The cup hen is the bird which we remarked on at the Crystal Palace as our choice; second small and pale in colour. The first pullet is decidedly fine, of a very pale shade of grey; second good in colour and promising to be an immense hen. Whites are good classes; size and combs seem to improve much in this breed. The two winning cocks are both fine and very equal. In cockerels the Palace award has been reversed, and we think rightly; the cup cockerel is a great beauty, intensely white; second square and fine. Mr. Cresswell carries all before him in hens; the cup winner is immense, we hear she weighs 9 lbs.; second a fine square hen. Pullets are a good class and even; first large, a little heavy in comb; second white and good; among the highly commended is the Oxford cup bird.

Cochins.—*Buff Cocks*.—First a fine bird, even in colour, with the exception of the wing, which appeared to us a shade too light; second in some points we liked better than the first, but he was spoilt by the white feathers on his legs; third we considered an ugly-shaped bird, and preferred pen very highly commended (564), the Palace winner, which was claimed for £50, the largest bird in the class, but he was not in such good condition as at Sydenham, and the variations of his colour we fancied were more conspicuous. *Cockerels*.—First very hocked, and rather leggy; second a neat bird, but we found nothing in the class to cause special admiration. *Hens*.—First a grand-shaped lemon colour in beautiful condition; second also a very good bird; third very even in colour; fourth we thought a little tinged in hackle, but the light was decidedly anything but good. *Pullets*.—First all that could be desired, perfect in shape, beautiful in colour, well feathered in leg, and in superb condition; second a good bird; third capital in colour; fourth neat. The competition between third and fourth with several of the highly commended pens was very close, but we agree with the Judge in his selections. The Partridge cards were not issued until it was too dark to make an inspection. *Whites*.—*Cocks*.—First and second both beautiful birds, very pure in colour; first a trifle the larger, but each clear away from all others in the class. *Cockerels*.—First a fair bird but rather hocked; second neat; 820 showed a little white in the lobe, or it would doubtless have been in the prize list. *Hens*.—Good. *Pullets*.—First and second nice birds; third small; 854 a large bird, pure in colour, heavily feathered but hocked, we presume too heavily for the Judge. Black classes were fairly represented.

Malay Cocks.—First a fine bird; second larger, and showed a greater strength of limb. *Cockerels*.—First a neat bird, but we thought him deficient in limb; second a stouter bird, but not so well made. *Hens* a fair lot.

Crève-Cœur Cocks.—First and second good birds, the competition being extremely close. *Cockerels*.—Entries of only average quality. *Hens*.—We did not like the winner; she was bad in colour, and appeared to have only size to recommend her. The second we thought should have been first, and pen 1037 (unnoticed), second.

Houdan Cocks.—The winner was a large bird, but had an ugly one-sided comb. We preferred 1065 (unnoticed) to any pen in the class. *Cockerels*.—First a large bird, fair crest, but toes pointing in all directions. *Pullets*.—We thought the winners correctly selected.

Spanish Cocks.—Five birds only put in an appearance, but they were all good, and those not obtaining a prize were otherwise distinguished. The first had a splendid lobe and was well shown; second was not quite over his moult. We thought the occupant of pen 1136 possessed a better face. *Cockerels*.—Very inferior to the exhibition at the Palace. First had an open face and a good quality of white, but scarcely the length of lobe we expect in a first-class show. Second the Palace winner very much out of condition; we considered he should have given place to his near neighbour, the very highly commended pen. *Hens*.—First had a very heavy face of beautiful quality. 1155 good lobe, but out of condition; pen 1151 an average bird. With these exceptions they were a very poor lot. *Pullets*.—First a large-faced bird, with a good lobe, but a little out of condition; second coarse, rest very moderate.

Polish.—*Black Cock*.—First a fine crested bird in lovely condition; second had a large crest, but too open. *Cockerel*.—First well crested; second larger, but not evenly parted. *Hens*.—First a beautiful bird, with a very close crest; second good; 1354 a large crest, but not even. *Pullets*.—We think one of the

prizes should have been withheld. Only two birds made an appearance, one of them being blind with roup. Golden cocks were fair. *Hens*.—In this class we thought pen 1377 the best in colour and crest, but our attention was called to a growth of small feathers on the leg, which kept her out of the prize-list. The winner was a well-marked bird; the second appeared a little wry-tailed. *Pullets*.—Second best in colour, but deficient in crest. In Silver pullets the first-prize bird appeared up in the back.

Andalusians.—This variety was shown in pairs. The winners were well matched and in excellent trim. 1422 a capital pen, but out of condition.

Game.—*Black Red Cocks*.—First good and fine in all points, especially fine head and hard feather; second good colour and fine quality, hard condition; third hardly so long in limb, but deserving his place; 1468 fourth, fine head, rich colour; 1472 and 1473 empty. *Cockerels* only a poor class, and far inferior to the usual Birmingham standard. First-and-cup good in quality of feather and colour, but very flat-shinned; second rusty-coloured but neat style; third rusty fluff but stylish, the Alexandra winner; fourth flat-shinned but tall and stylish, cut too close underneath throat; fifth a tall and reachy bird, good in colour and head. The principal failing in Black Red hens and pullets was the prevalence of dark eyes, which are too common. In hens all three winners have dark eyes, but are tall and good-shaped hens. Mr. Dutton's highly commended is good in colour and has rich red eyes, and style enough to merit a higher place. In pullets the cup winner is an extra smart one, but rather foxy; second is the Palace winner; third and fourth two very pretty coloured and neat pullets; and fifth a tall and pretty bird of good colour. This was one of the best classes in the Game section. The old Brown Red cocks were a good lot, first being a winner here last year, but not one of the modern lemon shade, still he is a handsome and stylish bird; second is the true lemon Brown Red, and won at the Palace; third too long in hackles and very dark in breast; fourth a very similar bird to second. Mr. Watson's highly commended is also a very good one. *Cockerels*.—First-and-cup, also the champion cup, is an extra good one in fine bloom, rich lemon, beautifully laced breast, splendid tail; a trifle more size would improve him. Second and third similar in colour and fine quality; the third a little too feathery; fourth good in upper colour, but rather light underneath and too heavily laced, good in head and style; fifth a good stylish bird of quite another stamp, being reddish, but tall and reachy, rather flat-shinned. The Brown Red hens and pullets were shown in so dark a place that criticism is almost impossible. The winners all appeared good in style, but some of them too dark copper-coloured in hackles, especially the cup and third hens and some of the highly commended pullets. *Old Duckwing Cocks*.—Cup to the bird which took second at the Palace; second a good and strong-framed bird with rich orange back; third a nice tight bird with full orange back, hardly so limby as winners. The cockerels were good; first and second as at Palace; third good shoulders, but not fine enough in head. Harley's highly commended (1659) is a better bird by far than third. In old hens Harley wins easily, a big strapping bird with immense reach; second very good, but smaller; third carries her tail too high. *Duckwing Pullets*.—First-and-cup the Palace winner, still unbeaten; second was also good and stylish, but dark-eyed; third a very pretty pullet, too long in body. The Blacks are falling off, only two cocks and two cockerels; all good, however, except the second old cock, which was very round-backed, quite enough to have thrown him. The winning hens and pullets were all smart and good, but darker in face and eyes than used to be considered correct; in fact the red-eyed and faced ones seem to be lost. *Old Pile Cocks*.—First the Palace winner; second too high in tail; 1746 good but small. The first cockerel is good and stout; second stylish, but bad-coloured. Pile hens and pullets both good in the winning birds and well judged.

Bantams.—*Sebrights*.—Winners a neatly laced pair of Silvers, cock a little faded; second Silvers also, cock not well marked, the hen we thought the best in the class; third Gold, very pale in lacing; 1822 were a well matched pair, and both clearly marked, but the hen was out of condition. *Whites*.—Five entries, nearly all good. First very pure in colour; second also nice in colour, smarter than the first, but blue-legged. Blacks with the exception of the winners were poor. The Game awards were not out at the time of our leaving, but we noticed a very handsome pen of Mr. Brownlee's, that we expect will be foremost among the Piles. Any other colour.—Only two entries. Black feather-legged.—We liked the second best, the first being very red in saddle.

Ducks.—The heaviest White Aylesburys weigh 21 lbs. 10 ozs. the drake and Duck; the heaviest Rouens are 23 lbs. 8 ozs. the drake and Duck.

Geese.—The heaviest White Goose and gander of Messrs. J. K. & R. R. Fowler weigh 48 lbs. 12 ozs., the heaviest Grey Goose and gander 49 lbs.

Turkeys.—The heaviest Turkey cock 35 lbs. 7 ozs., the heaviest

Turkey cock hatched in 1877 weighs 28 lbs., the heaviest of Turkey hens 20 lbs. 6 ozs. each, and the heaviest Turkey hens hatched in the present year 17 lbs. 3 ozs. each.

PIGEONS.

As regards the general arrangements of the Pigeon department of this great annual gathering we have nothing new to add. The same extraordinary and inconvenient up-and-down manner in which the pens are numbered is still carried out, and consequently the same disagreeable amount of dodging backwards and forwards and hunting up and down to follow the numbers consecutively has still to be undergone. How heartily we wished before we had done the Council would try to make some improvement in this respect. One excellent arrangement, however, we were very pleased to meet with again, and we know that the exhibitors generally will share with us in the feeling, in finding the birds again placed under the able and assiduous care of Mr. J. W. Edge as Superintendent of this department. He never seems tired of attending to their requirements, and wherever one looks cleanliness and comfort is everywhere perceptible. We know that the great length of time which birds have to be away from home at this Show keeps hundreds away which would otherwise be there, and we know also that before a superintendent was specially appointed many have suffered severely by sending their birds; but we can now say that every care and attention which an old and experienced fancier can possibly bestow upon them is bestowed, and beyond the mere length of time the birds are away from home we think exhibitors who would otherwise like to exhibit there have now nothing to fear in sending to Bingley Hall. Several alterations have been made this year in the schedule. The classes for Short-faced Balds and Beards are again amalgamated, as the change did not come up to the anticipations of the Committee. An additional prize is given to the Tumbler of Any other variety, and the Trumpeters are divided into two classes, Mottled and Any other colour. The silver cup hitherto given to Runts, Archangels, and Fantails is now competed for by the two former breeds only, and an extra one is given to the Fantails, and a third prize is also given to Fantails of any other colour. An additional cup is given to Jacobins, and that hitherto competed for by Jacobins, Turbits, and Owls is now devoted to the two latter kinds. An extra silver cup is given to the Dragoons and also to the Antwerps, and a selling class is opened for a pair of any variety of Pigeon with prizes of £2 and £1, the price of each pen not to exceed £2. The entries this year number 629 pens against 670 last year, and in many of the classes we fancied the quality was not quite up to the usual standard.

Carriers, as usual, head the list, and here especially we noticed, as in fact we did at the Palace, a great falling-off in the quality of the specimens, and our opinion in this respect in regard to both Shows was coincided in by several well-known Carrier breeders. We hope that this decline is not generally perceptible throughout the lofts of the country; but we fear that the innumerable shows which are now and have been held during the last year or two, and the high prices which are offered to breeders for their best specimens, are now beginning to tell sad tales. A good young bird now, soon after he is reared, is hurried into the show pen, and any experienced breeder knows that constant showing and successful breeding are incompatible. But now to the Show. Old Black cocks mustered nine, but beyond the prize birds there was nothing in the class worthy of notice. First was, we think, the second-prize Palace winner, a fine bird with good properties generally, but a little wedge-shaped in head, which rather detracted from his other good points; the second bird, belonging to the same owner, was better in beak wattle and narrower in skull, but the birds were no doubt rightly placed. Black hens only mustered six, Mr. Fulton taking first and the cup and second, but in our opinion the two birds should have changed places, for beyond having good head points we saw nothing in the cup hen to admire, while the second hen was not only good in head but in all her other properties as well. We thought her a charming bird. We also admired 2086 (Maynard), and although not in the competition with her heavier competitors, still a very handsome bird with youth on her side. Dun cocks had only four entries. Fulton first with an old and well-known winner, but which beyond his beak wattle is not a bird to be admired. 2092 (Maynard) second, though not so heavy very much more to our taste, a little short in face, but a good stout beak, capital colour, and for style a Carrier all over. Dun hens were a very good class indeed, most of the birds being large-bodied birds, stout in bill, and with plenty of wattle and style. Mr. Fulton, however, was an easy win with a very fine specimen which took our fancy immensely. Mr. Maynard's second, capital in her points, though not so well developed as her more successful rival, and grand in colour. Mr. Fulton's highly commended specimen will also bear examination. Altogether we considered the Dun hens the best class of the lot. Carriers any other colour were a fair class, mostly Blues, first being Mr. Stretch's Palace cup-winner, and no doubt in his right place here. 2106 (Waterhouse) an excellent bird, but out of condition. Second was a White, and as a White

Carrier a very good bird indeed. Young Black cocks numbered a dozen entries, first being the Palace winner, and both here and there we heard many expressions of doubt as to his age, and at Oxford, where he was shown, we understand he was passed over with several others as being over age. Whether such is the case or not we of course cannot say, but he certainly is as well as one or two others in the class, remarkably well developed for a bird of this year. We, however, liked 2117 (Billeyald), highly commended, a good, long-faced, stout-billed, stylish bird, capital in colour, plenty of distance between his eye and wattle, both of which were good, and a genuine young one; and 2120 (Mrs. Hallam) also highly commended, also a fine large bird, remarkably narrow in skull, and an excellent beaked bird, as well as any in the class. In young Carriers any other colour, first and the cup a young Dun hen, undoubtedly remarkably stylish, long in face, straight in beak, and stout for a hen, capital in eye—in fact, we thought altogether a beautiful bird, but withal a peculiar something about the shape of the back of the head we did not quite like, but no doubt, considering all things, she was in her right place. Second another Dun hen apparently, stylish, but rather fine. Rest of the class very poor.

Pouters taken as a whole were a very good show indeed, although rather small in the entries in the respective classes the class for any other coloured birds, which with one exception were all Black, being undoubtedly the best of the lot. The Whites were also exceedingly good. In Red or Yellow cocks first was a Red, very good in colour but sadly out of condition; he, however, carries his flights much too low—quite under his tail. No doubt when he was in condition he was a good bird, but he looks past it now. Second also was a Red, not so good in colour, but a fine cropped bird, his chief fault being too wide in the limbs. 2134 (Pratt), highly commended, we should have put higher up, being a tall stately bird with the most Pouter properties of any bird in the class, but being rather badly bishoped on one side no doubt threw him out. 2133 (Fulton), a Yellow, rather thick in girth and short of toe-feathering. Red or Yellow Hens.—First a Yellow, a very stylish bird, but short of marking on the crop, but a good first for all that. Second also a Yellow, the second bird at the Palace. 2138 (Fulton), another good Yellow. Blue Cocks.—First a good cropped bird with good limbs, and in fact a good bird throughout, but slightly bishoped on one side. We could, however, see little to choose between this bird and the one belonging to the same exhibitor in pen 2146, both highly commended and both very stylish birds. The second-prize bird was very good in his marking but rather too dark in colour. Blue Hens.—First rather thick in girth and droops her secondary feathers too much. We should have preferred the second-prize in her stead, being better in marking and a more stylish bird throughout. White Cocks.—First a very neat bird indeed, and we think the Palace winner. The second-prize we consider should not have been in the list, either pen 2152 or 2160 (both Pratt) being far superior birds, the former being the bird which was second at the Palace Show in the old class, although it is a young bird of this season. 2161 (Lang), highly commended, rather a taking bird and upstanding, but short of crop and limbs placed too wide apart on the body, although they are near enough at the hocks. White Hens.—First a very neat bird but short of limb, the Oxford cup-winner, we believe, and third at the Palace. Second also a good bird, but, like the former one, deficient in limb but a nice crop. 2166 (Fulton), highly commended, the hen which won so much twelve months ago, but now we think a very ugly bird and carries herself like a Duck. 2167 (Pratt), a very neat stylish hen in splendid condition; and 2169 (same owner), about the largest hen in the class, but somewhat out of condition. 2170 (Lang), a bird of this season, which promises to make a very good one. Any other colour cocks were all Blacks. First (Fulton) a well-known bird, but to our mind wanting in style. Second the best marked bird in the class and good in colour. 2174 (Fulton), highly commended, another good bird, but nearly swallow-throated. 2171 (Pratt), highly commended, the old champion Black now getting rather old for show. Any other colour Hens.—First-and-cup a stylish Black, excellent in colour and marking, and limb also fairly covered. Second also Black, a very long-limbed stylish hen, which we should prefer to the winner, although not quite so good in colour or marking. 2178, highly commended, Fulton's well-known Black hen which won the cup at the Palace, now altogether out of condition. To our mind she is sadly too thick in girth, and limbs too wide apart. In fact we cannot possibly see anything in her which in our opinion justifies her former achievements in the show pen. 2176 (Fulton), a very stylish mealy hen and very well marked.

Almond Tumblers were only a small class of some half-dozen birds, but there was nothing to approach two such birds as were shown by Mrs. Hallam. First and the cup was the charming bird, which was unanimously selected by all the critics as the bird which should have won the cup at the Palace. Second a rather larger bird, but beautiful in colour and spangling. Mr. Yardley also showed a charming little hen, a well-known winner; and a capital headed and well-coloured cock, which we

have more than once seen at the head of the prize-list, but now not quite in his usual trim. Short-faced Tumblers were a capital class of ten, first being a beautiful-headed Yellow Agate cock (Weston) and a well-known prizewinner, a little lighter in colour than when we saw him last, but a Short-faced Tumbler all over. Second was a Black Mottle, but we thought there were several other birds in the class which might well have filled its place. The Judge marked this as a very good class, but it would be interesting to know for what reasons. Balds and Beards had only three entries, first being a pretty Blue Beard and second a Red Baldhead. The other bird was a capital Blue Baldhead, rather low cut, but a splendid-headed little fellow.

Flying Tumblers.—Muffed Tumblers (Rosewing).—The cup went to a very handsome Red; second also Red Rosewing. Mottled.—Not much to say of this class; first a Black, apparently a hen. Muffed Tumblers, any other variety.—A most extraordinary class, containing a great variety of beautiful birds. About the best class of the kind we remember to have seen, and it is a pity the Judge had not more prizes to award here, which he could easily have done. First a handsome Red Badge; second a Blue Saddle, very heavily feathered; 2230 (very highly commended) was a pure white bird, pearl-eyed, very handsome, and heavily feathered, which took our fancy immensely. In class 163 (Tumblers, any other variety) the first and second prizes went to Mr. Yardley's well-known and handsome Yellow Mottles, the hen, a specially handsome bird, running the cup-winner very hard for his honour.

Barbs were not well represented, the cup going to a Red, rather large, but with excellent beak and eye properties. The young birds competed with the old for the cup, and two good specimens were first and second respectively. Many persons, however, preferred 2270 for first, but he was dark in bill, and doubts were expressed as to his age.

Trumpeters only brought five entries, among them, perhaps, the best White ever exhibited, the property of Mr. Shaw. The celebrated Mottle carried off the cup.

Jacobins.—Reds and Yellows competed together, and some excellent birds were exhibited in the class; the cup going to one of the long-feathered birds lately introduced. Second a small and charming Yellow, but which does not carry its hood so close. Any other colour.—A Black is first with an ugly flaw in hood, a very nice little Black second, and a good White third.

English Owls only brought three entries, the falling-off in this variety being something remarkable. First a Blue, which we did not like, and which we think should have changed places with the second-prize bird, a beautiful Silver in splendid condition and colour, but rather lacking in rose, otherwise a wonderful bird. Foreign are not a fine class. The two winners are a White and a Black; both good.

Dragoons were well-filled classes throughout, the Blue cocks being about the best in quality; and the Blue, Red or Yellow, and Silver cocks were well judged, but in Dragons any other colour we should unhesitatingly have placed the third-prize first. He is the old champion Grizzle; and we should have placed 2453, not noticed, but the best Blue in the class, second; and third to 2488, another Blue Chequer. In hens, any colour, the Oxford and Palace cup hen won the cup here, second being a Blue; both rightly placed. Dragons hatched in 1877 were a fair class, but we consider the first-prize bird was a mistake, its next neighbour, pen 2487 (Wood), being an easy win.

Antwerps were also large and well-filled classes, the Silver Duns especially so, but badly judged. If any of the three winners were entitled to a position the third-prize bird was the best. In Blues we thought 2505 (Hubbard), highly commended, and 2508 (Yardley), unnoticed, should have been first and second. Red Chequers.—Here we thought pen 2528 better than the third-prize bird. First was the old Red Chequer champion, which also won the cup as the best Antwerp cock. The Blue Chequers were well judged. Silver Dun or Blue hens.—We thought 2556 (Bradley), a Silver Dun, the best hen in the class; 2567 (Ludlow) was undoubtedly second, as placed; but we should have placed 2563 (Copeman) third. Red or Blue Chequer hens.—No fault to find here. Silver Dun or Blues, hatched in 1877.—The first-prize bird won by his colour only, being on a small scale throughout. Decidedly the best pen in the class was 2597 (Bradley), highly commended; while 2595 (Mapplebeck), highly commended, and 2596 (Slater), unnoticed, should have been amongst the winners. Young Antwerps, Red or Blue Chequer, hatched in 1877, were fairly judged. Speaking generally of the Antwerp judging we may say that the Judge has, in the majority of cases, entirely departed from the Birmingham standard and gone for small pretty birds, colour and condition having carried him away.

Runts are estimated rather in the scales than by the eye; the Silvers at present outweigh the Blues. Archangels are a good class. We like Mr. Harrison Weir's judging of them. He looks to other points besides a black tail, though we wish birds adorned (?) with aid of the grease pot were excluded. First is a very dark bird; third a good sheeny copper, a bargain at 30s.

Fantails.—White.—All here goes to flat round tails, while

style and motion seem disregarded. First has a large and splendid tail, though the feathers are very thinly set; the tail of third is particularly flat. Among the unnoticed are some capital birds of the Scotch style, among them the cup hen at the Alexandra and Crystal Palaces. The two winning Blues did not show to advantage when we saw them, for they carried their tails over their backs too much.

Nuns.—All the winners were Blacks. The first the only one that pleased us in flights. **Swallows.**—First a capital Black, second a Yellow, third a Red. To the latter we much preferred its owner's Black, 2339. **Magpies.**—An extra good Black is cup-and-first, a rich Red second, and a very high-cut Yellow third.

Turbits.—Red or Yellow are a very good class, most of the birds being remarkable for smallness and neatness. First-and-cup the little Yellow hen with marvellous frill, which scores her third victory at Birmingham at two and a half years old; second a Red, very dull in colour, but good in head and frill; third a small down-faced Yellow. In the other class a coarse foul-thighed Blue Shell is first, and a well known tiny Blue hen second. Among the unnoticed are a remarkable White (Fulton) and a remarkable Black (Cresswell).

The Variety class, as it always is at Birmingham, was a most attractive and interesting section of the display, and we think it was this year exceptionally so. Duplicate second and third prizes were awarded, but the duplicate first we are sorry to see this year is discontinued. First was the Satinette which was second at Southport; one second a Blue Domino, and the other second a Blondinette; the two thirds were a plain-headed Silverette and a clean-legged Blondinette, grand in head, and a beautiful bird in crest, colour, and markings. Among the many other birds in the class calling for notice was 2643 (Bott), a beautiful Satinette, which ought to have been noticed; and 2633, highly commended (Ludlow), a Blue Vizor, the bird which won at Southport, and which is, we believe, the winner of four silver cups among his other many achievements; but he was no doubt thrown out here on account of the soiled state of his flights and tail through the wires of the pens having been cleaned with grease, a great mistake, which has left a lasting mark for this year at any rate on many beautiful birds.

POULTRY.

BRAHMA POOTRAS.—Dark.—Cocks.—Cup and 2, Horace Lingwood. 3, R. Hargreaves. 4, E. Pritchard. *vhc.* F. Bennett. *Cockerels.*—Cup and 2, Horace Lingwood. 3, L. C. C. R. Norris. 4, C. H. Tindal. 5, R. P. Percival. *Hens.*—Cup, Rev. J. D. Peake. 2, E. Pritchard. 3, Mrs. F. S. Arkwright. 4, Horace Lingwood. *vhc.* T. P. Ye. *Pullets.*—Cup, 2, and 4, R. P. Percival. 3, Rev. T. C. Peake. 5, E. Kendrick, jun. *Light.*—Cocks.—Cup, E. L. Mills. 2, Lady Gwydyr. 3, H. C. White. 4, W. T. Tedd. *vhc.* R. E. Horsall. *Cockerels.*—Cup and 2, Haines. 3, M. Leno. 4 and 5, R. P. Percival. *vhc.* Horace Lingwood. *Hens.*—Cup and 2, H. C. White. 3, Horace Lingwood. 4, M. Hall. *vhc.* R. P. Percival. *Pullets.*—Cup, Horace Lingwood. 2, J. & W. Birch. 3, G. W. Peter. 4, M. Leno. 5, P. Haines. *Selling Classes.*—*Light or Dark.*—Cocks.—1, E. Kendrick, jun. 2, C. Morris. 3, W. McMath. *Hens or Pullets.*—1, Rev. J. D. Peake. 2, Mrs. H. Foulkes. 3, E. Kendrick, jun. *vhc.* W. T. Tedd. 3, Lucas, Rev. T. C. Peake.

COCHIN-CHINA.—Cinnamon and Buff.—Cocks.—Cup and 2, G. H. Procter. 3, J. E. Taylor. *vhc.* C. H. Tindal. *Cockerels.*—Cup and 2, G. H. Procter. 3, T. P. Ye. 4, C. Sidgwick. 5, W. A. Burnell. *vhc.* H. Tomlinson. 2, R. P. Percival. 3, F. A. Procter. 4, A. B. Smith. *vhc.* C. Bloodworth, Mrs. Allopp. F. Robertson, J. Bloodworth, J. Walker, W. A. Bindley. *Pullets.*—Cup, G. H. Procter. 2 and 3, W. P. Rylands. 4, J. Nelson. 5, W. A. Burnell. *vhc.* J. Nelson. A. J. E. Swindell. W. P. Ryland, Rev. G. F. Hodson. *Brown and Partridge-feathered.*—Cocks.—Cup, F. Robertson. 2, R. P. Percival. 3, J. Hendrie. *Cockerels.*—1, 2, and 3, R. J. Wood. *vhc.* H. C. White. J. K. and R. R. Fowler. E. Tudman. *Hens.*—1, E. Tudman. 2, R. J. Wood. 3, R. P. Percival. *vhc.* R. Jones. *Pullets.*—Cup, R. J. Wood. 2, T. Stretch. 3, E. Tudman. *vhc.* H. Tomlinson, J. E. Taylor. *White.*—Cocks.—Cup, A. Darby. 2, R. P. Percival. 3, Lady Gwydyr. *Cockerels.*—1, C. H. Tindal. 2 and *vhc.* R. Chase. 3, A. Darby. *Hens.*—Cup, A. Darby. 2, H. Tomlinson. 3, R. Chase. *vhc.* Lady Gwydyr. C. H. Tindal, Rev. A. W. Warde, Mrs. H. Shutt, H. Tomlinson. *Pullets.*—1, G. B. C. Breeze. 2, H. Tomlinson. 3, R. P. Percival. *vhc.* J. K. and R. R. Fowler. *Black.*—Cocks.—1, Lady Gwydyr. 2, Mrs. F. J. Cockerell. *Cockerels.*—1 and *vhc.* A. Darby. 3, E. Kendrick, jun. *Hens.*—Cup, A. Darby. 2, O. E. Cresswell. 3, A. Darby. N. Cook. *Pullets.*—1, Lady Gwydyr. 2, R. B. Wood. *Selling Classes.*—Cocks.—1 and 2, H. Tomlinson. 3, J. E. Taylor. *Hens or Pullets.*—1, H. Yardley. 2, W. A. Burnell. 3, H. C. White.

MALAYS.—Cocks.—Cup and 2, E. Stanley. *Cockerels.*—1, G. Burnell. 2, T. B. Lowe. *Hens.*—1, G. Burnell. 2, E. Stanley. *Pullets.*—1, T. Eaves. 2, G. Burnell.

CREVE-CEURS.—Cocks.—Cup, R. B. Wood. 2, I. Ward. *Cockerels.*—1, I. Ward. 2, H. P. Garde. *Hens.*—1, H. Stephens. 2, I. Ward. *Pullets.*—1, H. Stephens.

HOUDANS.—Cocks.—Cup, Mrs. D. Lane. 2, T. J. Levett. *Cockerels.*—1, I. Ward. 2, W. O. Quibell. 3, Mrs. Vallance. *Hens.*—1, C. Morris. 2, Mrs. Vallance. *Pullets.*—1 and 2, W. O. Quibell. 3, Mrs. Vallance.

SPANISH.—Cocks.—Cup and 2, E. Jones. *vhc.* D. M. Mills. *Cockerels.*—1, E. Jones. 2, J. J. Powell. *vhc.* J. Aldridge. *Hens.*—Cup, E. Jones. 2, J. Aldridge. *Pullets.*—1, J. J. Powell. 2, J. Aldridge. *vhc.* Mrs. Allopp.

HABUCHES.—Black.—Cocks.—1, Miss E. Wilson. 2, J. Long. *vhc.* H. Beldon. *Cockerels.*—Cup, R. L. Garnett. 2, J. Long. *Hens.*—1, J. E. Smith. 2, H. A. Clark. *Pullets.*—1, Rev. W. Serjeantson. 2, Robinson & Jagger. *Golden-pencilled.*—Cocks.—Cup, G. Ashpole. 2, H. Pickles. *Cockerels.*—1, J. Stuttard. 2, H. Pickles. *Hens.*—1, H. Pickles. 2, H. Beldon. *Pullets.*—1, H. Pickles. 2, J. Stuttard. *Silver-pencilled.*—Cocks.—1, J. Stuttard. 2, H. Pickles. *Cup, Robinson & Jagger.* 3, H. Beldon. *Hens.*—1, H. Pickles. 2, J. Stuttard. *Pullets.*—1, H. Beldon. 2, J. Stuttard. *Silverspangled.*—Cocks.—Cup, S. Fielding. 2, H. Beldon. *Cockerels.*—1, J. Fielding. 2, J. Stuttard. *Hens.*—1, H. Beldon. 2, Robinson & Jagger. *vhc.* Miss E. Browne, Ashton & Booth.

is no brood in a hive, as the young queen has not then begun to lay. In taking honey from the hive then nothing is destroyed but the combs. The honey is obtained, generally speaking, without the destruction of a cell of brood. The bees driven into an empty hive commence to build comb at once, and the young queen soon begins to lay. In fine weather combs are rapidly built and as rapidly filled with brood in the hive of the turn-out swarm; but to interfere with it while it is in a state of prosperity in every sense—breeding bees, building combs, and storing honey would be well-nigh ruinous. Very little honey would be obtained, all the brood of the hive would be destroyed, and the poor bees would have to commence housekeeping and house-furnishing at a later and more unfavourable season. Your correspondent will do well to abandon the idea of having three harvests of honey annually, or of driving bees from their hives twice in a season after swarming. In fine seasons a second harvest of honey may be obtained from first and early swarms by treating them like old stocks—viz., by taking swarms (called virgin swarms) from them as soon as they are ready, leaving bees enough in them to hatch the brood; then, three weeks later, turning all the bees into empty hives. But I do not take virgin swarms, neither do I recommend others to take them. I find it more profitable to super or cke swarm hives than it is to take virgin swarms from them. It should be borne in mind that in filling hives with combs bees have to consume a good deal of honey.

Bees that are fed-up with syrup and have their hives pretty well filled with combs in September make the best of stocks and the earliest swarms on the following season.—A. PETTIGREW.]

MR. PETTIGREW'S LARGE HIVES.

I THINK "B. & W." misunderstands Mr. Pettigrew's argument as regards large hives being equally good for poor as well as rich honey districts. I have always understood his argument to be as follows:—The egg-laying powers of the queen are almost unlimited. A small hive restricts those powers, and consequently affords only a small population. A large hive gives full scope to those powers, and consequently supplies a large population, and a large population will gather more honey in any district than a small one. But Mr. Pettigrew further teaches that large hives require large swarms, or, failing these, two or three swarms in the first instance to stock them; and, as heat is required for a large early population as well as room for the queen's laying power, he strengthens his large hives by the addition of condemned stocks in the autumn. Have those who have failed with large hives thus fully carried out Mr. Pettigrew's system? I do not follow his system, but have with advantage adopted much of his teaching, which is applicable to bar-frame as well as other hives. The question, and it is an important one, is simply this: What is the best size of bar-frames and shape of hives to secure the largest early population, and what is the best system for their successful management?—O. B.

P.S.—It would greatly help to the settlement of this question if some bar-framists would give a fair trial to a really large frame.

THE SWANS ON THE THAMES.—The report of Mr. E. C. Robins, Swan warden of the Dyers' Company for the current year, states that an interview was had with the Lord Chamberlain with regard to the objections of some of the residents and anglers on the banks of the Thames that the Swans ate fish and spawn; and it was satisfactorily proved by the analysis of Mr. F. Buckland that the outcry was much exaggerated. The birds do not eat the fish or spawn by preference, but only incidentally while feeding upon the vegetable matters with which the river abounds. However, the Crown has decided not to increase the number of Swans, but to maintain the total of grown birds and cygnets at about 400, those of the Dyers' Company at sixty-five, and the Vintners' at forty-five, which was the average of the last seven years.—(City Press.)

OUR LETTER BOX.

DOMINIQUE FOWLS (C.).—The Dominique is like a Rose-combed Cuckoo Dorking with bright yellow legs and lacking the fifth toe. They are not more profitable layers than the breeds you name. Their eggs are of fair full size. They are hardy and do well in confinement, but we know no respect in which they are better than those breeds we already have. Their yellow legs are a disadvantage if they are intended for market; they make a considerable difference in their value.

DORKING AND BRAHMA CROSS (Idem).—A Silver-Grey Dorking cock will do as well to cross with Brahma hens as an ordinary Grey. Nothing is, however, gained by it, and as a good Silver-Grey is worth certainly twice as much as a common Grey, it would seem, as you seek profit, more conducive to that end to sell the expensive bird and buy a cheaper. You must, however, recollect a Silver-Grey must not have a speck of white on the breast or a shade of white in the tail. If it has it forfeits all claim to the class.

HOUDANS (Idem).—It is very desirable that the cock and pullet in a pen should resemble each other as closely as possible. If the birds, although of different shades, are equal in other points, there can be no hesitation. Put a dark hen with a dark cock, and vice versa. But it is well to say the point is not so material with one hen as with two. Two hens or pullets put with a

cock must match. A dark and a light one put in the same pen would have little chance of success. Considerable latitude may be and is allowed for the difference in shade between cock and hen provided the points that prove purity of breed are undeniable. Nevertheless we repeat, if all other points are equal it will be advisable to match cock and pullet as closely as you can in every particular.

LICE ON FOWLS (Ledbury).—Dusting them with Sooth snuff under the feathers will destroy the vermin.

MIS-SHAPEN EGGS (E. W. B.).—We should think from your fowls one after the other laying the same mis-shapen eggs that some of the materials necessary for the formation of the shell were wanting. We say some of them, because unless the shell were partly formed there would be no shape at all; but the egg, as is frequently the case, would be quite soft to the touch. Lime is a necessity, and it is most profitably given by throwing down in their haunts a barrowload of bricklayers' rubbish, old plaster, ceilings, &c. This not only supplies them with what they want, but it also amuses them, causing them to turn over, scratch, and search for the necessary ingredients. Ground cats (such as they have in Sussex), they also form shells, as they contain chalk. Where all these appliances exist and yet the eggs are faulty in shell, there is some mistake in feeding, or the birds are out of health, and the secretions are at fault. The food should be barley meal or ground oats slaked with water morning and evening; whole corn, barley, or maize, varied at times with kitchen scraps, for the midday meal. If they are in confinement they must be supplied with good-sized sods of growing grass. We believe this will be found a remedy.

FOWLS DECLINING (W. D. H.).—We believe there is something your fowls eat which disagrees with them. There is but little of it, and they have not all access to it, or all would suffer alike. Or it may be your food is wrong, and those that are weak or sickly become victims. What is the flooring of the houses? If wood, stone, or brick that will in a great measure account for it. Even in the healthiest yards there is sickness at this time of year and some die, but it appears you have been suffering for months. At this season of the year the fowls should be fed three times per day. There is little for them to find except when there is thrashing going on and the barn door is open. The change of weather, the damp, cold, and the long nights are trying to them. We advise you to feed as we have named in the preceding answer. Let your house have an earthen floor and we believe the deaths will cease.

METEOROLOGICAL OBSERVATIONS.

CAMPDEN SQUARE, LONDON.

REMARKS.

- 28th.—Bright sunny day throughout; colder; wind and rain commenced at 11 p.m.; gusty during the night.
29th.—Heavy rain and windy in morning; fine and bright afternoon; starlight evening, but rain at 11.15 p.m.
30th.—Fine morning; rainy and dull afternoon; clear at night.
1st.—Dark, foggy, rainy morning; sunshine at intervals after 11 a.m., but a damp day; starlight evening.
2nd.—Rather fine morning, bright sun at times, but on the whole a raw damp day.
3rd.—Dark dull day, with rain at intervals.
4th.—Dull day, but no rain till 5 p.m.; showery afterwards.
A dull damp week, with very little range of temperature.—G. J. SYMONS.

COVENT GARDEN MARKET.—DECEMBER 5.

Our market still remains quiet, and though the supply of first-class goods is getting very short prices do not vary.

From observations taken near London during forty-three years, the average day temperature of the week is 45.3°; and its night temperature 38.2°.

HARDY AZALEAS.

GREENHOUSE Azaleas as represented by the beautiful varieties of *A. indica* are esteemed indispensable in every conservatory where spring flowers of high quality are appreciated. The value of these handsome flowers is admitted by the extent—almost universality—of their culture; nor is this preference to be wondered at, for whether we regard the massive grandeur of the richly-coloured varieties—glowing pyramids, brilliant globes or dazzling standards—or the soft and delicate tints of the neutral colours—pillars of beauty, chaste yet gay, they command admiration wherever they are seen in the fresh bright garb of perfect health. No wonder, I say, can be expressed that these beautiful plants are so popular, but there is room for surprise that another branch of this floriferous family is so systematically neglected—I mean the beautiful varieties of Azaleas *pontica* and *mollis*. I hesitate not to say—and I am certain all who are acquainted with the best varieties of the sections named will give acquiescence—that these charming hardy shrubs are of at least equal importance as the greenhouse varieties, the fame of which is so firmly established.

Many are the lovers of flowers who possess gardens but not greenhouses, and to those the Indian Azaleas are prohibited plants; but no one who has the means of growing a Laurel, Rhododendron, Dahlia, or Rose need be denied the enjoyment of the beautiful hardy Azaleas referred to. Neither are they exclusively adapted for outdoor display. They are charming as seen in beds or borders, as all must admit who have seen them in good condition; but they are equally striking when the flowers expand under glass. Each head of flowers of some of the *pontica* varieties and their crosses is set in a fringe of the freshest of fresh green foliage, which enhances its beauty. These charmingly “encircled heads” of attractive flowers are not only extremely beautiful, but some of them are as sweet as Honeysuckles, and nearly all of them emit a delicate perfume. They are thus conservatory flowers of the first order of merit, and are equally valuable for cutting for room and vase decoration. Their colours are extremely varied, yet are distinct from those of most other plants flowering at the same period.

The effect produced by the varieties of *A. mollis* is of a different character—more bold and more imposing. So floriferous are these plants that they appear when at their best as being all flowers. So dense are their masses of colour that it is necessary to have green-foliaged plants to afford them relief—to set them off. They are gorgeous but not gaudy, for even the yellow varieties possess a peculiar softness of tint which subdues but does not impair their brightness.

Both the *pontica* and *mollis* varieties are forcing plants of undoubted merit, and should be employed in decoration wherever such shrubs as Rhododendrons, Kalmias, Lilacs, Roses, &c., are grown for conservatory embellishment in

early spring. These deciduous Azaleas force as well, but perhaps not quite so quickly, as any of the shrubs named, and with which they are quite worthy of being associated. Well-budded plants obtained from the nurseries at the present time and firmly potted in light soil and brought on gradually in a vinery or forcing house will in due time give a reward commensurate with the attention that has been bestowed on them.

For forcing purposes the plants may be obtained from any nursery at home or abroad, and may be potted and placed in gentle heat forthwith, and they will flower satisfactorily within a few months from being potted. If judiciously treated after having flowered and their buds are set and foliage kept healthy throughout the summer they will flower still earlier the second season. I have had plants both from English and Belgian nurseries which have arrived in such good condition that they have flowered equally as well as have others which have been potted from the reserve garden at home. Thus they are tractable plants, easily managed, and as certain in producing good results as any plants can be that are accelerated in growth, and made to flower some time before their natural season.

For shrubbery and general garden decoration they are admirably adapted. When associated with Rhododendrons they enhance the effect of those gorgeous shrubs by the distinct colours imparted, and which show to great advantage amidst the rich foliage of those queenly evergreens. Azaleas of the *pontica* and *mollis* types are, too, for anything that I know to the contrary, as hardy as Rhododendrons; at any rate I conceive they are sufficiently hardy to pass uninjured through the ordinary winters of any district in Great Britain and Ireland.

These valuable hardy flowering shrubs and excellent forcing plants cannot be considered without associating with them the memory of a famous horticulturist—the late Mr. Louis Van Houtte. It is to his enterprise, sagacity, and the skill retained in the celebrated establishment at Ghent that we are chiefly indebted for the finest varieties that have been distributed. In a recent issue of the Journal reference was made to an English Memorial Committee who are in possession of funds enabling them to offer prizes at the next Ghent Quinquennial Exhibition in honour of the man to whose skill and energy the horticultural world is so greatly indebted. That is a graceful tribute to real worth; but a greater memorial than even that of the remarkable man whom all delight to honour is found in the fine varieties of hardy Azaleas which he originated and which will remain as bright records of his fame—mementos of a man whose name, like that of the genus of plants with which it is so intimately associated, can never die.

Those who have not seen the thousands—the acres—of these plants in the grounds at Gendbrugge can form no conception of the magnitude of the trade in them—trade which extends to all the nations of the civilised world. I have seen that great collection at different seasons of the year—in early summer when the plants have been flowering, presenting a sea of bloom, and in the autumn when

they have been taken up, "mossed," and dispatched to the different kingdoms of Europe and to America, and it is not easy to determine which sight was the more imposing; but either affords sufficient evidence of the great importance of the plants in question.

Yet these Azaleas are not seen everywhere. They are still comparatively scarce in the gardens of this country, because in the great majority of them they are not represented at all. From many, very many conservatories, too, Ghent Azaleas are absent, a circumstance that can only be explained by assuming that the finer varieties of them are not known. Neither have the hardy Azaleas been extensively exhibited at spring and early summer shows. We read occasionally that "Messrs. Rollisson sent a fine group of *Azalea mollis*;" or that "Messrs. Veitch contributed a splendid collection of *Rhododendrons*, interspersed with effective plants of *Azaleas pontica* and *mollis* in variety." The last-named firm, which are always well abreast of the times, have recently obtained a first-class certificate for a new variety of much promise named *Couleur de Paille*. It belongs to the *mollis* section, and is very rich in colour, as if partaking of the nature of the old and valuable Chinese *Azalea sinensis*, which is so effective for decorative purposes, and even for exhibition. Since the ice is fairly broken it is more than probable that other new varieties will be raised or introduced by English growers, which will do much to popularise this useful family of hardy flowering shrubs.

In a future communication I will refer to some new and old varieties.—*NOMAD*.

THE APPLE AND THE ROSE ELECTIONS.

As one interested in the Apple and its manifold varieties I desire to thank Mr. Killick for the very useful and intelligible form he has given us in the election of some of the choicest sorts. For many years I have been anxious for something of the kind being done, and must admit being much disappointed at the Rose being more than once honoured with the distinction of its varied forms being paraded to the world while the Apple remained neglected. It may be all very well to call the Rose the queen of flowers, and I suppose it would sound very much like floricultural treason to dispute the assertion; but have not other florists' flowers held a very high position at the court of the Goddess of Beauty, and have not the flowers fallen into neglect and disregard? and who is there that can say the Rose will not follow them? Much as the latter is and has been admired, I do not think that the most enthusiastic of its admirers have gone so far in giving fabulous prices for their pets as did their grandfathers for their favourite Tulips and some other kinds of flowers fashionable in their day; and when we take into consideration the much greater abundance of wealth of the present day to what there was formerly, the honour of riding a hobby very hard in the cause of floral display belongs more to a past generation than to the present. But I will not pursue this matter further, but rather let us take the case of the Apple and see what claims it has on our attention.

I do not think I am speaking beyond the bounds of general acquiescence when I pronounce it the most important fruit cultivated in this country, and certainly of the most importance, not the least of its claims being its antiquity, for we are told our Saxon ancestors had their orchards, their cider, and other luxuries furnished by this fruit. What improvements have taken place in the culture and management of the Apple are but very imperfectly handed down to us, and how much altered is the Apple of to-day from the fruit of Saxon times it is difficult to conjecture; and it is not at all complimentary to writers on gardening matters to find the merits of Roses so freely discussed while Apples remain comparatively neglected. Nurserymen's lists, although some of them are highly creditable, do not furnish all the information needed. Cannot fruit-growers, therefore, give us their own opinions of the respective varieties? The growers of Roses dilate on the beauty of their *Maréchal Niels*, their *Alfred Colomb*, and the other thousand and one names, and why cannot the merits of fruit be discussed with the same freedom? An Apple may and often does present a certain beauty of form which may to its admirers equal that of any Rose, while on the score of utility the comparison is of course all on one side.

The Apple which has attained about the highest position in this immediate neighbourhood as a good-sized fruit and early-bearing variety has been adverted to by Mr. Killick, and is

best known in the locality as Stone's Apple, the original tree growing on the farm of a gentleman of that name, the name of the farm being Loddington. I see it has also been called Loddington Seedling; but as Mr. Killick has so well described its general character I need add but little, except my mite of recommendation to its worth as an early fruit, of its good bearing qualities as a tree, and its general good appearance as an Apple, added to which it keeps better than most Apples that come into use in August and September, for I see it was one in a collection of twelve sent by Mr. Skinner, an extensive grower in the neighbourhood, and whose collection took the first prize at a recent exhibition.

Now, an Apple that is one of the favourites at market in August and still in good condition in November is in itself a sufficient recommendation, but its good bearing qualities are its most important claims to notice, and so good is it in that respect that it is seldom one meets with a large tree of it, although, perhaps, no single variety has been planted so extensively in the neighbourhood of Maidstone, and its popularity does not seem in the least diminished. Its most important opponent as a fruit to send to market in August and September is Lord Suffield, but by many it is considered superior to the last-named popular kind; and I expect it would be difficult to find specimens of Lord Suffield to exhibit with other kinds at the end of November. It has, however, its admirers.

I have often urged the claims of the Apple as being quite as important as that of the Rose for consideration through the medium of a gardening periodical, as local varieties are not often known beyond the bounds of the district where they originated. Whether this one originated as Mr. Killick suggests is uncertain. I have frequently seen the original tree, as I lived within a quarter of a mile of it for more than twenty years. It is impossible to say whether it has been grafted or not, but it has been pretty widely distributed during the last few years. One of its names, given to it I believe by a London fruit salesman, was Mapson's Seedling; and so high a character did Mapson's Seedling obtain, that there is a story told in the neighbourhood of an extensive fruit-grower having heard of its productiveness procured some grafts, and gave instructions for his Stone's Apple and others to be cut down and grafted with the kind, when after the second year it was found to be identically the same variety that he had cut down—viz., Stone's Apple! Such things I believe have occurred with other fruits; but when the result is such a good fruit as the one in question it is all very well. As a worthy friend of mine said many years ago when new Grapes "so called" turned out Black Hamburgs, there was no harm done.

A variety of Apple which seems to be an especial favourite with Mr. Killick, and is also much esteemed by many others, is the Cellini. Mr. Killick will, I am sure, forgive my differing from him in reference to this fruit; for although it is undoubtedly a fine-looking Apple, it is too tender to carry to a distance well, and consequently when the baskets of it are opened at market the produce does not look so well as when it left home. This defect may perhaps have no weight with many of your readers, but it is important to the growers for market. I simply mention this, not with any view of disparaging a really good bearing and pretty fruit, but in fairness the good and bad qualities of each ought to be impartially recorded. At a future time I may possibly advert to the merits or demerits of other varieties of Apples, and I should be very pleased if others would do the same, for it is only by records of experience that we can determine the sorts best suited for different purposes and different districts. I do not want less of Rose lore, which so many enjoy, but more of hardy fruit experience recording, which cannot fail to afford both pleasure and instruction.—*J. ROBSON*.

PICEA NOBILIS SEEDLINGS.

On clearing a border on which I have a very good and tall *Picea nobilis* my gardener found three seedlings from it, evidently of one, two, and three years' growth, grown under some Holly trees which stand close by. I am well acquainted with growing seed of this tree, as I now have seedlings 6 feet high, but to do this they have to be sown and carefully preserved under cover until fit to move.

I am given to understand also that the seed never ripens properly in this climate, but my experience appears to point to the opposite. The parent tree itself gives every year large numbers of cones which have to be cut away, or their weight

might break the branches if allowed to remain. Have any of your correspondents met with a similar occurrence—viz., trees growing from seed without any protection?—FRED. WALTON, *St. Cuthbert's, Albrighton.*

NOTES ABOUT GLADIOLI.

HITHERTO we have not seen the Gladioli grown to that extent which on its merits it deserves to be. The great destruction to the corms by disease has necessitated their being sold at a price which has put them beyond the reach of many who would gladly grow them. We are told about and read of the Tulip mania which once existed, when the bulbs were purchased at fabulous prices. Fortunately things are now changed, and a common-sense price is all the public will go to. Our endeavours towards making the Gladioli still more generally the popular flower it deserves to be renders it incumbent that this disease, which so devastatingly attacks it, ought to command our closest observance. Once secure for the Gladioli a more hardy constitution, then for this noble flower we might safely predict a bright future. One day, or rather one year, we are delighted with magnificent spikes and of the finest form and colour; the time comes round again, and it may be that we may reap again, but more than probable for our much-prized beauty we look and look in vain. It has gone without so much as leaving a small offset behind.

I have frequently thought that hybridisers were running too much after flowers of high quality, and that constitution very apparently was almost if not altogether ignored. We all know how hardy is the old *Brenchleyensis*, and also that fine soft sweet flower of much better class, old *Penelope*. Were I to commence to raise seedlings, this latter crossed with others of higher colour and of the best constitution I could procure would be those I would breed from. Regarding *Penelope*, whoever yet saw a well-grown spike disgrace a stand? It shows a greater breadth of bloom than have its compeers, and I have seen ladies pick it out admiringly when staged with others at fifty times its cost. When we secure varieties of equally good quality also as hardy, then nurserymen will be able to supply bulbs at half the present average price, and the public will materially increase their purchases.

In the way of finding a remedy I ask, Where does the disease first commence its attack? Many will say in the corm. My decided opinion is that the diseased bulb is only the effect of the disease, which I contend first attacks and then destroys all or many of the roots. The first outward sign is the foliage turning to a sickly yellow. Now, as soon as you like after first noticing this, let the plant be taken up and it will be found that the points of the roots are also sickly and yellow, and soft and mushy. Certainly we have the diseased roots before we have the diseased corm, or at least I have always found it so, and for an amateur I have grown a large collection. Of grubs the wireworm is occasionally a pest by its eating through the heart of the spike just above the corm, but perhaps I suffered less this way than some by using liberally nitrate of soda.

Regarding suitable soil, a rather stiff loam I think suits them best, and after experimenting I at last used only new cow manure, both dug-in and for mulching during summer. Of varieties my practice was to grow a few of each of the best-named sorts and then to grow largely of purchased seedlings. The French seedlings were no good. I may or may not be correct in my surmising, but I have many times thought that the stock of named varieties was largely made up from seedlings; and with child so like parent, and hundreds of parents with no children raised by the ordinary way of offsets, there is all the more empty bags to select from into which a corm of an ordinary good flower can be placed, and for which a fair price can be obtained. Have you never noticed from half a dozen corms having flowers much alike but not the same? With the Messrs. Kelway's seedlings at 20s. a hundred I was much better pleased. I had from them many very good exhibition flowers. The corms and spikes generally were of good size, and with many judges size goes a great way. I daresay I have had thousands of corms raised by Mr. Banks of Deal, and without in the least colouring from many of them, but flowers of finer or better quality I never saw. A few years ago I exhibited rather largely (not these last three years), and once had the pleasure, at the International Show held at Manchester, of drawing the attention of "D., Deal," to my stand of thirty-six spikes nearly all cut from Mr. Banks's seedlings, and which very nearly contained every flower I could command. My turn was second, Messrs.

Kelway first, and a Scotch firm third. Mr. Banks, it may be well to note to save so worthy a gentleman trouble, sells none of his corms retail; he disposes of them to the trade. Those wishing to plant Gladioli in their borders, I strongly recommend them, save *Brenchleyensis*, not to buy cheap named sorts, but to buy seedlings from any of our English raisers; and those wishing in a cheap way to grow for exhibition I recommend them to follow the plan I followed.

Just another thing I would draw attention to. All flowers look best when exhibited on green; over and above some fresh green foliage of their own behind each spike, let them stand deep amidst *Asparagus* foliage stuck amongst the water in the tubes.—J. WITHERSPOON, *Red Rose Vineries, Chester-le-Street.*

PROTECTING CHERRIES.

Few who have had experience among Cherries have not at times been much concerned about how to protect them from birds. This accomplished, other difficulties come within the grasp of the experienced cultivator. Explicit and practical as "A NORTHERN GARDENER" made the espalier system in the *Journal* of 22nd ult., yet while many may have their arrangements so complete, with others the system detailed may be almost impossible; and excellent as the plan is they cannot carry it out.

In my own experience I have seen Cherries kept from the pets (for so they are here), no difficulty being in the way, only a scarcity of old herring nets. These nets can be procured from fishermen when they have done with them for a nominal price, their width being from 12 to 14 feet. I once had under my care a number of trees planted against a brick wall about 12 feet high, which were closely netted with some of the above-described nets as soon as the fruit began colouring. The nets were looped on tacks at the top, ends, and bottom. When we wanted to gather a dish we had only to remove a few loops along the bottom, go under the net, and pick away without the least inconvenience. I have seen the trees so loaded with fruit that they would have charmed the heart of any gardener who had employers who were fond of Cherries. The variety was *May Duke*.

On the other hand standards are not so easily protected from blackbirds, thrushes, and jackdaws, none of which will take any affront except shooting at them with intent. An orchardist close by here has a few very large Cherry trees, as large indeed as forest trees; just as the fruit commences colouring he makes it a point to have a watch on about 3 A.M. In the open side of the approach to the trees he has a scone erected, so as the watch can advance without being observed by the birds. Gun in hand the first enemy seen is fired at, and if not detained is so frightened is not likely to return for some time without much caution. Provision is made for the cautious birds by placing a bare branch on the top of one of the trees near the Cherries, so as the timid birds may alight first on the bare or naked branch, where it will have the best view from, and while it is looking about it the man in the scone can fire with impunity as far as the Cherries are concerned. This plan may at first sight appear a difficult one, still in the long run it is better to give a little attention when the fruit is ripening than having the dissatisfaction of seeing a crop destroyed after a whole year's care and attention.—B. G., *Co. Down.*

THE OLD ROSES.

Yes; as Mr. Witherspoon says let us have some Moss Roses. I would not say a word to damage the reputation of the beautiful Roses that we now hear and see so much of; they are worthy of all the praises lavished upon them, but by all means let us have some Moss Roses. It is to be regretted that those charming old favourites of the past have fallen into comparative obscurity, and are fast becoming "things of the past." The bards of all nations have sung their praises with all the glowing eloquence that is lavished on the present race of new Roses. I maintain that in point of beauty none can surpass our glorious old Moss Roses. What language can do justice to the plant designated the "daughter of heaven," the "glory of spring," and the "ornament of the earth?" No other hardy flower gives such beauty combined with such fragrance as the Rose.

One of the choicest of Roses (old though it be) is the *Provins*, *Rosa provincialis*, said by some to be from France, while others say Holland is its native home; others again assert that

it belongs to the vicinity of Damascus. It is also known as the Cabbage Rose. We have no certainty as to when we came in possession of it. The old Damask Rose, *Rosa damascena*, appears to be almost lost to cultivation, and yet in bud we have not a more desirable Rose. The York-and-Lancaster Rose has been referred to; it is sometimes met with, and may be restored to favour again. No Rose in the bud is more beautiful. We used to have another striped Rose in *Perle des Panachées*, also the Old Village Maid and New Village Maid, but they appear to have fallen into disuse, why I am not able to say. But to my mind the Rose of Roses is *Rosa muscosa*. There is some doubt as to its origin. Some think that it is an offspring of the Provins Rose, others attribute it to *Rosa centifolia*.

Why the Moss Roses find so little favour I am not able to say. They are not difficult to cultivate, and I think they should have a class to themselves at exhibitions. They are often seen in all their glory by the cottage homes of England.

They are best increased by layers, but they may be increased by budding on other stocks, yet they like their own roots best. They often send up strong suckers. These with care make good plants. The white varieties are a little delicate, but with care they can be successfully cultivated. There are several kinds of Moss Roses that are worthy the notice of cultivators. One of the very choicest is the Crested Provins, then we have *Rouge de Luxembourg*, *Malvina*, *Baronne de la Flèche*, *Comtesse de Murinais*, *Alice Leroy*, *Moss Lanei*, *Baronne de Wassenaeër*, and *Capt. Ingram*, with others that might be named, and which ought to be more freely cultivated.—A. LOVER OF OLD ROSES.

ECONOMY IN HEATING GREENHOUSES.

PATENT STOVES v. FLUE.

"RESPICE FINEM" (page 416) does not seem to like my saying that the cost of heating his small house was, as compared to mine, excessive. First of all he tells us that my advocating the flue is, to say the least, retrospective, and had I done so I could not do otherwise than admit the force of his argument; but the fact is I never did advocate the flue as the best means for heating. Were I to advocate any particular apparatus I should decidedly advocate that which I think every person possessing a knowledge of floriculture and its requirements for attaining success would do—namely, a boiler and hot-water pipes. "RESPICE FINEM" appears all at once to have discarded the patent stove, and in preference thereto has adopted one of his own design. Why does he not give us the particulars thereof, that others may derive some benefit from his knowledge and experience?

But to answer his queries. The question of growing any particular plant, such as *Gardenias*, *Gloxinias*, *Stephanotis*, &c., was not raised by me. All I did was to criticise his expenditure for heating a house not larger than 10 feet long by 6 wide to the extent of 50°. My house is one-third larger; it is sheltered only from the east wind. The temperature is the same; and although the plants are not the same they are such as require for their well-being a constant temperature of 50°. But has anyone ever heard of an average temperature (a term used by me in my former paper) of 50° for horticultural purposes meaning 20° at one time and 80° at another? What plants does "RESPICE FINEM" think would exist under such conditions? To my mind such an average temperature means keep as near to it as you possibly can; neither let your thermometer register many degrees below nor above it.

For many plants in a greenhouse it is exceedingly injudicious to raise the temperature above 50° during winter. If it is plants will grow weakly, and as a consequence they cannot rank amongst the number of well-grown plants, which after all is the first consideration whatever plant it may be.

Let me in conclusion tell "RESPICE FINEM" that my greenhouse is not one simply for the preservation of *Geraniums* over the winter.—L. HAKEMAN.

CAMELLIA FIMBRIATA.

I FORWARD to your notice a flowering twig of *Camellia fimbriata*. It is from a bush plant, about 6 feet in diameter, growing in a pot. You may observe that the tendency of pot culture when the plants are in good order is to give plenty of flowers. The plants do not grow so strong as those planted out, and the foliage is not so large either, consequently the flowers show rather better. It might be said that the principle that governs the flowering of the *Camellia* well is just the

same that is required for the perfection in blossom of an Apple tree, or indeed any other plant; without the wood is well ripened the same perfection is not attained. The plant from which I cut this spray is certainly not so thickly flowered all over the plant; still the buds, opening and to open, are plentiful.—R. M. A.

[The spray, although not more than 6 inches in length, contains four expanded flowers and as many unopened buds; the foliage is also glossy and healthy. We never saw a better example of culture of this beautiful *Camellia*.—EDS.]

HOW TO PLANT AND COOK POTATOES.

In the first place the land requires drainage, in the second place trenching 18 inches deep, and in December or January quicklime should be applied at the rate of 1 ton to every 10 poles; or gas lime, which will answer equally well, at the rate of 1 ton for every 10 poles of ground. When the land is dressed all over with the lime the next thing is to ridge up the ground 2 feet apart and to let the ridges remain so until the 1st of March, when the Potato planting may be commenced if dry; if not, wait for another week or two, beginning with the earlier sorts, such as the Ashleaf and Early Rose, and finishing with the late sorts, such as the Jersey Blue: that will be about the 1st of April. I am afraid it would take up too much of your valuable space to mention the different manures I have tried for the last thirty years, but I have found where the lime was put at the rate of 1 ton for every 10 poles of ground the Potatoes were good and free from disease. If anyone should doubt this let them try 1 pole with 2 cwt. of gas lime. Storing Potatoes is best done out of doors in pits with a good sprinkling of common sand, and then they can be covered up with straw and earth to the thickness of a foot or more if the weather should be severe.

For cooking Potatoes have plenty of water, salt, and a good fire, and whenever the first crack is seen pour the water off and steam them till they are ready, and they will turn out like "balls of flower."—J. G., *Lynwood*.

CANDYTUFTS.

AMONGST the many kinds of hardy plants suitable for the decoration of flower gardens in spring and summer there are few that will surpass the genus *Iberis*. The majority of the species are perennial, but some are annuals, and a few are biennial, are found in the mountainous districts of the south of Europe, and have a dwarf, shrubby, spreading habit, seldom rising in height more than 18 inches, and usually have white flowers. The most suitable position in the garden for them is a rockery, but for the mixed flower border or for an edging to beds they are also very effective.

One of the best known kinds is *I. saxatilis* (synonymous, I believe, with *corifolia*), a plant unequalled for an open rockery, and when in bloom it forms a complete mass of white; but to do it justice it should have a good soil, and if large boulders of stone are placed about it, it will spread over them, and in a few years will make a handsome plant, associating well with *Arabis alpina*, *Aubrietia purpurea*, *Alyssum saxatile*, *Saxifragas*, *Sedums*, and other alpine plants.

Iberis Garrethiana, *I. sempervirens*, *I. gibraltarica*, *I. Tenoreana* are all fine species, and are equally good (though old-fashioned) as pot plants for indoor decoration. They strike readily from cuttings taken off after flowering, inserted in sandy soil, and placed in a close frame till rooted; they may then be divided and planted in rows outdoors, and the year after may be planted where they are wanted, there to remain, as the less they are disturbed about the roots afterwards the better. The *Iberis* may also be raised either from seed sown as soon as it is well ripened, or in the spring, placing the seed pans in a close frame, and gradually hardening the young plants till June, when they may be planted out, but be taken care of till well established and sufficiently strong to take care of themselves.

The annual kinds should find a place in every garden, however small; for what is more gay when in bloom than white and crimson Candytuft? and useful for cutting as well. They may be had in bloom from June till November by successional sowings. If sown the latter end of August and protected a little from hard frost the bloom will be a little earlier than spring-sown seed; but the beginning of April is quite early enough to sow in the majority of gardens, for if the winter is very cold and wet the majority of the young plants perish.

The seed should be scattered thinly in well-pulverised soil, covering the seed slightly, and when the young plants are about an inch in height thinning them to 4 or 5 inches apart will strengthen and greatly improve those that are left; sowing annuals thick and leaving them like so much Mustard and Cress only causes poor growth and short duration of bloom. If another sowing is made the early part of June in a damp

Fig. 85.—*Iberis corifolia*.

and more shaded aspect a good supply of bloom may be had till November. The white and purple Rocket Candytuft are good and cheap kinds; and *C. Dunnettii* is a fine crimson variety with a good robust habit.—A. HARDING.

[The *Iberis* figured above is the true *corifolia*, but there is another often confounded with it from a similarity of names called *corraefolia*, that has much larger flowers and broader leaves, which is probably the sort referred to by Mr. Harding. The preferable name for *corraefolia*, which is a garden hybrid, as its synonyme *coriacea*, by using which much confusion will be prevented.—EDS.]

NATIONAL ROSE SOCIETY.

ANNUAL GENERAL MEETING, DECEMBER 6TH.

In accordance with one of the rules of this Society that the annual Meeting be held on the first Thursday in December, about twenty members assembled in the comfortable room of the Horticultural Club on the afternoon of the above date, amongst whom, besides the Hon. Secretaries—Rev. H. H. Dombrain and E. Mawley, Esq.—we noticed the Rev. C. H. Bulmer, Dr. Hogg; Messrs. Jowitt, Scott, McIntosh, Cant, W. Paul, G. Paul, Turner, Cutbush, Mayo, Dean, Hawtrej, and Corp. Mr. Jowitt, the winner of the first challenge for the fifty-guinea challenge cup offered by Messrs. Cranston & Co., was unanimously elected Chairman of the Meeting. Letters had been received from some distant members, including the President, Rev. Canon Hole, expressing regret at not being able to attend.

The minutes of the last meeting having been read, a letter was read from Rev. J. B. M. Camm tendering his resignation as additional Hon. Secretary, he being unable to continue in the position to which he had been recently elected; and Mr. G. Paul moved and Mr. Bulmer seconded a motion that Mr. Camm's resignation be accepted, which was carried *nem. con.* After a desultory conversation it was not considered necessary to appoint an additional Secretary.

The next subject brought before the meeting was the balance sheet. At a previous meeting Mr. McIntosh had kindly undertaken to audit the accounts, but as he had not received the balance sheet until Tuesday evening and had not had an opportunity of examining the vouchers he was necessarily not able

to discharge the duty he undertook in time for the meeting. The accounts, however, had been audited and signed by a professional accountant. The income of the year amounted to £417 12s. 4d., and the expenditure was returned as £417 8s. 2d. After discussing some of the items of expenditure, all of which were considered necessary, it was suggested that further discussion on the subject be deferred until the vouchers had been examined; whereupon Mr. W. Paul proposed and Mr. Mayo seconded a resolution that the balance sheet be examined and submitted to an adjourned meeting, which was passed without a dissentient.

The important question of "the future," and especially as to where the next National Rose Show should be held, led to prolonged discussion. The Hon. Secretary had been in communication with the authorities of the Agricultural Hall, the Floral Hall, the Westminster Aquarium, and the Crystal Palace. The Agricultural Hall could be had for one day for £50, or free by taking the Company into partnership, sharing the expenses and profits. The Floral Hall could be had for the same time at a rent of £100, a suggestion being made that if the Show was held at the time of an operatic performance an arrangement might be made for the audience visiting the Show. The Manager of the Crystal Palace offered the Society a hundred guineas and to provide all conveniences for the Show to be held there; and a similar offer was made by the Westminster Aquarium Company. After considering the nature of the several propositions it was eventually decided on the motion of Mr. Cant, seconded by Mr. Turner, that the offer of the Crystal Palace Company be accepted, the Secretary of the National Rose Society being directed to negotiate with the Palace authorities to obtain a day in the last week of June, if possible other than Saturday, Mr. Bulmer having strenuously urged the inconvenience of that day to clergymen, many of whom are ardent patrons of Rose shows. If a Saturday is insisted on by the Manager of the Crystal Palace, then June 29th to be the day of the Show. The chief, indeed almost the only objection to the Palace, was the inconvenience of trains from the west of England, which do not arrive in time for the exhibitors from that important district to stage their collections by the usual hour of judging; and on this account Mr. G. Paul suggested that an extra hour should be allowed in the morning for staging, so that Roses from the west, always so formidable in competition, should be fully represented. The whole matter was eventually left in the hands of the Secretary, who being in possession of the views of the meeting was desired to make the best arrangements possible for a one-day show at the Crystal Palace. In the event of the National Rose Show being held as proposed it is understood that there will not be a Rose show in addition at the Crystal Palace, thus there will be one metropolitan show the less, which was considered by most or all of the exhibitors present to be an advantage rather than otherwise, the general impression of the meeting being that there are "too many shows."

The question of a provincial show received the long and earnest consideration of the meeting. A strong and general wish prevailed to afford the northern growers an opportunity of exhibiting. It having been ascertained that Roses were included in the schedule of the Royal Horticultural Society's Show which will open at Preston on July 9th, and continue for five days, it was the general opinion of the meeting that the National Rose Show should be held prior to the Preston date. A strong feeling prevailed against the "clashing" of shows, and, as Mr. G. Paul said, "both interest and loyalty must prevent them running against that of the Royal Horticultural Society."

Attention was directed to the suitability of several places, but Manchester appeared to meet with by far the most favour as the place for holding the first provincial Show of the National Rose Society. Cheltenham, Bath, and Birmingham were also mentioned, and one or the other of them would probably have been more strongly urged as the place of meeting had not the feeling prevailed that they are beyond the radius of the northern growers. Manchester having been decided upon, the question arose and was seriously discussed as to whether the Show should be held in association with, or independent of, a local horticultural society. Mr. Bulmer was strongly disposed to go "on their own hook," and his views were promptly endorsed by Mr. Mayo. Other members were also inclined to make the "venture," but the majority deemed it advisable to adopt a safer policy for the first time and to gather experience. The "own hook" experience of the past had evidently a sobering effect on the meeting, and its advocates did not gain enthusiastic support. It was eventually decided, on the motion of Mr. G. Paul, seconded by Mr. Cant, that the Secretary communicate with the Council of the Manchester Botanical and Horticultural Society with a view to negotiating for the Show to be held under their auspices on the same principle as the Crystal Palace Show; the Manchester Show to be held for one day during the first week in July. It was further decided that in the event of arrangements not being made for holding the Show at Manchester, that Cheltenham "be tried," and should that fail also the provincial Show for 1878 to be abandoned.

The last question on the agenda paper was the appointment of the Committee. After a short discussion it was unanimously agreed that the Committee continue as at present constituted with the addition thereto of the names of Mr. Burnaby Atkins, Mr. Jowitt, Mr. Arkwright, and Messrs. Keynes, Prince, and Corp. It was admitted that while many of the members were necessarily unable to attend the meetings in London they were still able and willing to do the Society good service in the respective districts. The Secretary suggested that in addition to the large General Committee a smaller Executive Committee be appointed to transact the routine business of the Society. The suggestion was promptly agreed to, and the following amateurs and nurserymen were duly appointed—namely, Rev. Alan Cheales, Capt. Christy, Mr. Jowitt, Mr. Scott, and Mr. Hawtry, and Messrs. Cant, Cutbush, W. Paul, G. Paul, C. Turner, and the two Secretaries, this Committee to carry out all practical details of management, and to summon a General Committee meeting when they deem it desirable to do so. At a previous meeting Dr. Hogg and Rev. J. T. Boscawen were appointed Vice-Presidents of the Society, but on the minute being submitted for ratification Dr. Hogg pointed out that in consequence of his many and urgent duties he felt it incumbent not to accept any more official positions, however much his sympathies were with the objects with which his name might be proposed. He further, on reference to the rules, observed that only one Vice-President was requisite, “and where,” he added, “can you find a better than Mr. Boscawen?” “Nowhere” was the response, and that gentleman’s nomination was unanimously ratified, Rev. Canon Hole, of course, remaining the President. A proposition having been made of the desirability of appointing a Treasurer, Mr. Scott, on being requested to do so, consented to accept the position, expressing his willingness in reply to a question to “do any amount of work within his power to further the interests of the Society;” Mr. Scott thereupon was duly appointed.

Mr. Cant towards the close of the meeting expressed some sound observations on the necessity of suggesting some rules of guidance for judging; a matter so important ought not, he thought, to be left to the various fancies of different men whose tastes on some points varied so extremely. Mr. Cant’s remarks met with general acquiescence, and it was freely admitted that “something should be done in the matter”—a hint for the Executive Committee. Mr. Mayo also directed attention to the importance of some suggestions that had appeared in the *Journal of Horticulture* on the advisability of offering prizes for Roses grown within a short radius from London; also on the importance of publishing the names of the judges previous to the show. Several members concurred in the remarks of Mr. Mayo—another hint to the “executive.” Mr. George Paul then gave a broad hint to the members by purchasing a copy of the “Rosarians’ Year Book,” for the cost of which Mr. Dombrain, not the Society, is responsible. The “hint” and several copies were at once “taken.”

A cordial vote of thanks to the Chairman terminated a harmonious and united meeting.

BRITISH PLANTS WORTHY OF CULTIVATION IN GARDENS.

WILDLINGS that adorn the dewy meads, deck the moorland in beauty, spangle the swamp, and adorn the water are ever welcome; each has some peculiar beauty, every geological strata, each change of landscape has its special flowers; some are curious, others quaint, all acceptable. The wildlings of Nature combine ornament with use, each plant having some peculiar adaptation. Unlimited luxury is found in the beholding of our native gems which are attractive in spring, summer, and autumn by their blossoms, foliage, and fruit. The study of plants in Nature not only affords pleasure, but enlarges the ideas, expands the mind. Cultivated plants contribute in a higher degree to the enjoyment and comfort of man, inasmuch as they are made to afford to the fullest extent the necessities as well as luxuries of civilised life.

Wild flowers, I mean native plants, have to a greater or lesser extent been cultivated from time immemorial. Some in their original, but a greater number in improved form, are at present found in gardens. A majority of cultivated plants are, however, exotic—many very beautiful, but some it must be said pale into insignificance before our native beauties. We ransack every clime of its floral treasures; while beautiful plants growing at our doors are passed by—neglected. Some of them are common, and a few are rare; therefore the cultivator of native plants may have equal cause to be proud of his collection as one whose plants are principally exotic. The lover of the curious, choice, and rare has his wants catered for in hardy native plants as well as in tender, in exotics, which I will briefly endeavour to show.

Orchises.—Some of the loveliest of all the plants that adorn our fields and woods are found in the Orchid family, adding in no small degree to the “motley meadows glory and delight.”

Orchis mascula (Male Orchis or Early Purple Orchis) is found in moist meadows and open or only partially shaded spots in woods, in rich moist loam of medium texture, its leaves spotted black, its flowers in May bright pinkish purple, lip spotted. The flowers are deeper coloured in the open than in shade, the higher-coloured flowers not unfrequently fragrant. It attains to a height of 9 to 12 inches. This forces well, and is very handsome as a pot plant, quite charming among Hyacinths.

Orchis morio (Meadow Orchid) is profusely distributed in damp meadows in medium-textured loam. Its flowers in May form a lax spike 8 or 9 inches high, the flowers being purple, white, and green, lip marked with dark spots. This also forces readily, and is a superb pot plant. It is the commonest of our native Orchises, but is nevertheless very handsome.

Orchis maculata (Spotted Orchis) has pale purple or flesh-coloured flowers spotted or streaked with darker tint or lilac purple in June, attaining to a height of 18 inches, is one of the finest, thriving in partially-shaded moist ground in rather strong loam, but prefers moist healthy pastures. Does well in pots.

Orchis latifolia (Marsh Orchis) is found in moist meadows, having broad spotted leaves and pinkish flowers, purple-crimson spotted, in June 12 to 18 inches high. The finest plants I have seen were in dampish partially-shaded ground facing east, soil 1 to 2 inches of vegetable debris overlying strong loam. It is fine for pots.

Orchis pyramidalis (Pyramidal Orchis) is found in meadows in heavy loam overlying chalk, but I have found it in heavy loam upon the liae formation. Its fine spikes of rosy purple seen in the grass shine like amethysts set in emerald. It flowers in June and July, and is very handsome.

Gymnadenia conopsea (Gnat or Fragrant Orchis) is found in meadows on high or hilly ground in July with rose or red spikes of flowers, in heavy loam overlying chalk, but not unfrequently without a limestone stata. It is very sweetly scented and grows 1 foot high, flowering in June and July.

Gymnadenia viridis (Frog Orchis) has green flowers, and is certainly singular, 9 to 12 inches in height, and is found in meadow pastures in moderately strong loam, usually in combination with vegetable debris in June and July.

Gymnadenia albida is a pretty white-flowered kind and sweet, about 6 inches high, appearing to prefer a soil composed of a peaty loam, flowering in June and July.

Habenaria bifolia (Butterfly Orchis), white, 1 foot high, May and June, flowers sweet, partially shaded ground in woods, in loam, with vegetable debris over the loam or intermingled.

Listera ovata (Twayblade or Wood Orchis), flowers green, small, in a slender raceme about a foot high in May and June. Heavy loam and moist, covered with vegetable debris.

Epipactis latifolia, purplish spotted yellow, 18 inches high, wet ground partially shaded.

Ophrys muscifera (Fly Orchis), lilac purple, May, in heavy loam over chalk, 9 inches.

Ophrys apifera (Bee Orchis), lilac purple, with a velvety centre (bee), 9 inches, heavy loam, and rich. June and July.

The preceding all thrive in an ordinary border of rich loam free of stagnant water, for though moisture-loving it is moisture percolating through the soil in their habitats, the rich soil of our borders compensating in a measure by the humus for the apparent greater moisture of the soil where the plants grow naturally; indeed, the plants are much finer, develop wonderfully under cultivation. *Orchis mascula*, *O. morio*, *O. maculata*, *O. latifolia*, *O. pyramidalis*, *Gymnadenia conopsea*, and *Habenaria bifolia* are splendid border plants, the first-named three being very much finer under cultivation than wild. *Orchis morio*, which had spikes not over 8 inches in length gives them over a foot in length, finer alike in foliage and bloom. My only regret is that I did not in the flowering season “spot” more plants of *O. mascula*, *O. morio*, and *O. maculata*, of which there apparently are several forms, some nearly white; in fact, we collected eight apparently distinct forms of the three species, the woods being very profusely sprinkled with these plants. By spotting I mean marking where the plants grow, for I find it does not answer to lift the plants when in flower, that being best deferred until the stems fade, then lift with a ball, going deep enough to secure some soil beneath as well as around the roots. The roots are usually 2 to 3 inches beneath the surface, seldom over 4 inches deep. We merely remove the surface soil so as to free it of grass or

weeds, and pot or plant as the case may be from 2 to 3 inches deep, using rather strong fibrous loam and leaf soil. Water freely if grown in pots when in growth and until the foliage commences to decay, then plunge in ashes in a sheltered situation, the site being well drained; the rains will after this be sufficient moisture. Introduced to gentle heat in January they will come in with spring bulbs, and are truly grand, their handsome foliage and superb spikes of bloom being charming. I will note a few more that are, perhaps, more curious than ornamental, and which so far as I know do not succeed in an ordinary border.

Orchis fusca (Lady Orchis or Brown-winged Orchis).—The upper part of the flower brownish purple, lower lip white, finely spotted. Sometimes it is not over a foot high, but on a peaty loam and rather strong over chalk, is 2 to 3 feet in height, with flowers proportionately large.

Orchis ustulata (Dwarf-winged or Scorched Orchis) is found in chalky pastures. Its brown or rusty purple flowers with coarse spots, and low close growth distinguish it. Three to four inches high, flowering in May and June.

Orchis tephrosanthos (Ash-coloured flowered or Monkey Orchis).—Flowers lead-coloured, more or less variegated, on a tall spike about 18 inches high. Found on chalky hills in peaty loam, flowering in May and June.

Malaxis paludosa (Bog Orchis) is found in peat or turf bogs, having yellow and green flowers in August or September, growing 3 or 4 inches high. Does well on the margin of a pond in sandy peat.

Opherys aranifera (Spider Orchis) has green flowers in May. Very singular, growing about 9 inches high, and is found in light soil on chalk.

Opherys fucifera (Drone Orchis).—Purplish and green flowers in May and June. Nine inches to a foot in height. In chalky pastures in heavy loam.

Opherys arachnites (Cobweb Orchis).—Brown flowers tinged blue. In May and June. About 9 inches high. Heavy loam among chalk.

Neottia spiralis (Lady Tresses or Ladies' Traces) has spikes of whitish flowers in August and September, and sweet, the flowers all pointing one way. Seldom over 8 inches in height. It grows in chalky upland pastures.

Neottia nidus-avis (Bird's-nest Orchis) is found in chalky woods in loam with a surface-covering of vegetable debris, and differs from a majority of British Orchises in the roots being fibrous instead of bulbous. Its appearance is not unlike a drooping Oak leaf, the roots crossing each other like the sticks of a bird's nest.

Aceras anthropophora (Green Man Orchis) has its flowers in a lax spike, greenish yellow, with a reddish border, but is very unlike man unless it be a hung traitor. Chalky pastures in strong loam. Flowers in June, attaining to a height of 12 inches.

Cypripedium Calceolus (English Lady's Slipper).—Purplish brown, slipper (lip) clear yellow. Leafy stems 12 to 18 inches. Heavy loam and limestone.

Cephalanthera rubra.—Flowers purplish red, 18 inches or more in height, flowering in June and July in heavy loam over limestone, but not unfrequently over grit, with a little vegetable debris. Woods in partial shade.

Goodyera repens has white sweet flowers in July and August, and is found in woods at considerable elevation partially shaded, in leaf soil or decayed vegetable debris, interspersed with sand, the debris being that of moss as well as leaves. 6 to 9 inches.

All Orchises have more or less of shade; if in the meadows the grass affords protection from the scorching sun, and in woods they are more or less protected from the sun by the trees; yet the best specimens are found in partially shaded situations only. Those described as growing in loam over or among limestone or chalk should have pieces of that substance mixed with heavy loam, a good depth of limestone be placed at the bottom in good-sized lumps about 9 inches thick, and over this 9 inches depth of the loam and limestone mixed in about equal proportions, employing surface loam preferably to that taken from a depth. The site must be well drained, and the exposure facing east, with a projecting rock or bush that will shield the spot from cutting winds. The soil must be kept moist, water being given copiously during growth, pouring it between the plants and not over their foliage; and after flowering a slight mulch of cocoa refuse may be given. Those growing in woods should have shade from midday sun, the several requirements of the plants being met at the base

of rockwork having different aspects; good drainage being essential, with a thorough moisture of the soil; none of our native plants experiencing a dry season, yet the moisture they receive is percolating and thorough. The roots are not unfrequently in contact with the limestone, from which they may derive support.—A.

SCOTTISH HORTICULTURAL ASSOCIATION.

THE ordinary monthly meeting of this Association was held at 5, St. Andrew Square, on the evening of the 4th inst. There was a large attendance of members. The President (Mr. M. Dunn of Dalkeith Palace Gardens) occupied the chair. Fifteen new members were duly admitted, and seventeen new names were proposed and seconded for admission as members at the next meeting.

The subject treated was the "kitchen garden" by Mr. Lawrence Dow of Laughton Hall Gardens. At the outset he urged upon young gardeners the necessity of devoting great attention to the proper management of the kitchen garden, so as to keep up a constant supply of first-class vegetables. Some were very apt to overlook this department in their anxiety to have a fine display of bedding and greenhouse plants. He then in a practical and lucid manner described the different methods of treatment by which he had been most successful in growing Potatoes, Onions, Jerusalem Artichokes, Parsley, and Asparagus. Several members expressed concurrence with Mr. Dow's views as to the importance of the subject, and also as to the modes of culture pursued. Mr. Dow received the thanks of the meeting for his paper, and at their request agreed to continue the subject at a future time.

A communication from Mr. James Morrison, Preston Hall Gardens, was read advocating the autumn planting of the Potato, and attaching great importance to the proper ripening of the seed tubers. A vote of thanks was passed to Mr. Morrison for his excellent contribution. The subject for the next meeting was announced to be the "Phlox and Pentstemon" by Mr. James Grieve, Pilrig Park Nursery.

NEW BOOK.

The Rosarian's Year Book for 1877. Edited by the Rev. H. H. DOMBRAIN. London: William Blackwood & Sons.

THIS little volume furnishes information that must be acceptable to all Rose-growers, for it contains contributions from Rev. A. Cheales, Rev. Canon Hole, Mr. G. Paul and others.

The object of the editor, we presume, has not been to diffuse practical instruction so much as to furnish pleasant reading on a congenial topic; yet Mr. Paul's contribution on stocks, supplemented by observations by Canon Hole, is eminently useful. The opening chapter on Rose-showing by Mr. Cheales is as fresh as the blooms at 4 A.M.—the hour recommended for cutting for the show. After enumerating the delights of preparing, exhibiting, and winning, the other contingency, losing, is thus referred to—

Do not abuse the judges. They have done their best, and deserve our sincerest sympathies. Judging Roses is no bed of Roses. "Truth should be told," say the Turks, "with one foot in the saddle." But it should not be essential after judging to take the first train and get off as soon as possible! Neither, again, come down upon your unfortunate gardener. He cannot help it if somebody else's soil is better. Let us carry our Christianity even with our Rose-growing, and learn to rejoice in the gain of another, even though it involve our own disappointment. One thing more, one more delight I must mention, and that is the delight of giving away the prize Roses. Send to those who have not any. During the rest of the season help one of the flower missions. If you so much enjoy those splendid flowers about your drawing-room, think of the brightness they must shed round the sick-ward of the hospital! Let these lead them—have they led us?—to thank the Great Giver of all good things. That is to carry love of Roses beyond the world.

Rose! for the banquet gathered and the bier;
Rose! coloured now by human hope and pain;
Surely where death is not, nor change, nor fear,
Yet we may meet thee, joy's own flower, again!

NEWTON HALL.

NORTHUMBERLAND is by many regarded as a "county of coal" almost exclusively. It is pictured as honeycombed with mines and surface-strewn with black refuse. Its atmosphere is regarded as repulsive—contaminated with smoke, which obscures the light of the sun, rendering the trees stunted and the pastures barren. It is true that these conditions exist, but only to a very limited extent in comparison with the aggregate

area of the county. Some districts are black enough, and, to coin a term, are vegetably destitute, but others are both picturesque and fertile. It is true there may be mines below, but there are verdant hills and fruitful valleys above them. If there are trees black and stunted in one place there are splendid specimens green and luxuriant in others, and these largely predominate. If one locality is dismally garnitured with coal heaps, others far more numerous smile with fruits and flowers. If long rows of pitmen's cottages break the soft flowing lines of the landscape and stir not the soul of the artist and poet, they shelter many a contented, thrifty, bread-earning and wealth-winning family—wealth which is seen in many a stately mansion, many an extensive and well-wooded park, many an excellently appointed and ably managed garden. Northumberland may be a black country, but it has nevertheless a very bright side, for in few counties are the industrial classes better off or the affluent more genuine and generous. Some of the bright places of the county have from time to time been noticed, and one worthy of being added to them is Newton Hall.

It may be said at the outset that Col. Joicey is the owner of Newton Hall and an extensive tract of land surrounding it, and Mr. Wardle is the gardener. The greatest honour pertaining to the owner, an honour which commands the respect of all men, is that he has won his position by his own efforts. Laborious, persevering, and far-seeing beyond his fellows, he has risen and risen until he has found his level, and that a high one. Perhaps no county has afforded more striking instances of industrial and commercial successes than Northumberland. Instances are afforded by names that will never be forgotten, for they are indelibly engraved on the historic tablets of the nation—George Stephenson and Sir William Armstrong. Equally signal, and achieved by means not less honourable if necessarily more obscure, have been the successes of many others, and amongst them Col. Joicey. His grand inheritance is indomitable work; his reward, not vast possessions and great wealth only, but in rendering assistance to deserving objects public and private, and making those about him happy and contented.

Mr. Wardle, like his employer, is a man of ability and perseverance, and is a successful representative of his calling. Not only is he a skilful cultivator, but is a raiser of new plants, and one, of which many gardeners know the value, bears his name—*Allamanda Wardleana*; he has further considerable competency as a landscape gardener, as many recent improvements in the gardens and grounds testify. Alterations have for a considerable time been carried out on an extensive scale; indeed, the place has been entirely remodelled since Col. Joicey purchased it nine years ago.

One of the latest improvements has been the formation of a suitable approach to the mansion. This has been a work of no small magnitude, for the carriage drive is fully a mile in length, proportionally broad, and traverses an undulated park-like district. This fine road has not only been thoroughly drained and well constructed with a sufficient depth of "metal" surfaced with gravel to render it firm and clean at all times, but it has been made as level as a railway by excavation—lowering the hills and raising the valleys. The margins of the drive have been boldly treated and planted. The temptation here must have been great to have planted a formal mixed shrubbery; but correct taste would have risen in rebellion against the adoption of a gardenesque style to which the surroundings are so manifestly inappropriate. On both sides of the drive the plants and shrubs are arranged in irregular groups. Hardy Heaths have been extensively employed for forming a semi-wild carpet, also Periwinkles, dwarf Hypericums, Ivy, and low-growing plants of that nature. There are also large groups of Furze, Broom, &c., with breadths of shrubs of different kinds. Where excavations have been done the side banks are planted with such trailing plants as *Cotoneasters* and others of that nature, and even *Brambles* are not ignored. Conifers are also planted in groups at appropriate intervals and in suitable situations. Everything is planted closely in order to cover the ground quickly and to produce a semi-wild effect, which is so pleasing when, as is the case here, the position is suitable. Many thousands of trees, shrubs, and Conifers have recently been planted on the estate, and the collection of them is regarded as the most complete in the north of England.

This natural system of planting referred to is not altogether a new feature at Newton Hall, for of older drives near to the mansion the sides afford examples of the plan which may

be said to be in a matured state. The distinct groups, irregular thickets, and bold masses of shrubs (chiefly perhaps shrubs of dwarf and procumbent growth with the striking contrasting hues of foliage) produce an admirable effect—very different and much more imposing than if they had been arranged on the patched and dotted system that usually prevails. The mode of planting adopted is evidence that the teachings of Nature have not been ignored, but, on the contrary, have been followed with greater freedom and fidelity than is generally fashionable. Colonel Joicey will in a few, very few, years be the gainer by the adoption of this free and easy style, and his gardener's reputation will be proportionally enhanced.

The mansion is a much larger structure than is represented in the distant view of it as seen in the engraving. It has been considerably enlarged, and further additions to it are contemplated. Internally its fittings and decorations cannot fail to arrest the attention of the observer. The paintings alone have involved a cost of £80,000; they are incidentally alluded to because they were brought under notice by traversing the corridor leading from the conservatory which conducted us into the interior of the mansion.

The conservatory, which is partly shown on the left of the mansion (fig. 86), is noteworthy both for its size and contents, also because it was erected by Col. Joicey's own workmen under the instructions of Mr. Wardle, who supplied plans and working drawings of the several details. It is 140 feet in length, 40 feet in width, and 39 feet in height. It is encircled by a gallery, to which access is had by a spiral staircase. In appearance it is plain yet very light, being simply a large lofty span-roofed structure, the roof being supported by light pillars and braced with cross ties and girders; these are draped with climbers, which hang in festoons and contribute materially to the ornamentation of the building. The more conspicuous of the roof plants are *Cobæas*, *Passifloras*, and *Tacsonias*, *T. Van-Volxemi* being represented by a variety having flowers unusually rich in colour. The main body of the house is occupied by a large bed containing many plants which are noteworthy on account of their size, cleanliness, and luxuriant health. Only a few of the plants can be referred to. Those which chiefly arrest attention are perhaps the Tree Ferns. *Dicksonia antarctica* raised from spores by Mr. Wardle are now towering specimens having a spread of fronds of 15 to 20 feet. Equally fine is *D. squarrosa*. These are remarkable specimens considering their age, and are in exuberant health. A pair of *Cyathea dealbata* are about 11 feet high, with a spread of fronds of 18 feet. Some fine Palms also command attention, notably splendid specimens of *Chamærops Martiana* and *Fortunei*. *Camellias* are in remarkably fine condition; a plant of *Alba plena* annually produces two thousand blooms. The green-foliaged specimens are relieved by variegated *Yuccas*, *Aralia Sieboldi variegata*, and the conspicuous *Eurya latifolia*, which is 7 feet high and 3½ feet in diameter and excellently furnished in every part; it is highly effective. Some well-grown examples of *Arquearia excelsa* also show to great advantage. The specimens noticed are planted out sufficiently thinly to develop and to show their fine proportions, and their good effect is enhanced by the carpet of *Lycopodium denticulatum* which covers the ground. On a side stage specimen ornamental-foliaged and flowering plants are arranged.

At the end of the conservatory farthest from the mansion is a fernery. It represents a wild cavernous-like arrangement of rocks with rugged passages. Plants are arranged in appropriate nooks, and are thriving admirably. Conspicuous is a fine example of *Cyathea medullaris*, and *Monstera deliciosa* is growing luxuriantly and fruiting freely. *Woodwardia radicans* is growing in baskets associated with other suitable plants. It is a cool retreat—a pleasing change from the conservatory, and is made additionally enjoyable during a sultry day by the constant trickling of water into a pool at the base of the rocks. It is proposed to extend the conservatory, so that this enjoyable fernery will be under the same roof and become a part of the same structure.

Further on—travelling westwards—we arrive at a large and lofty structure devoted to stove plants. Some of the specimens would be formidable antagonists if brought into the exhibition tent. *Crotons variegatum* and *angustifolium* 10 feet high, handsomely formed and in superb health and colour, are not to be slighted. *Allamanda Wardleana*, 7 feet by 4½—the true kind—covered with flowers 8 inches in diameter, is not to be despised. *Rondeletias*, *Clerodendrons*, and other flowering plants are similarly large and fine. Palms, *Dracænas*, *Crotons*,

&c., are represented by healthy plants of recent introduction; for instance, Mr. Williams's attractive *Croton Queen Victoria* has found its way here, and Messrs. Veitch's fine golden trilobed variety *Earl of Derby*. Other plants must be passed; but one, an old one, demands notice—*Cissus discolor*. This plant, with leaves nearly a foot in length and in rich colour, is a fine feature in this house. It clothes the end wall, and for the purpose for which it is employed no plant in cultivation could produce a better effect. Adjoining the stove is a large vinery. It is 150 feet long and wide in proportion, and at the end of the vinery is a large span-roofed house devoted to Heaths and other hardwooded plants. This important range of glass, being in immediate connection with the mansion, renders the vinery somewhat incongruous, and since others are now erected in the kitchen garden this house will be taken down and its site be turned to an ornamental purpose.

At the front of this range of glass structures is the flower

garden, which in summer is occupied with bedding plants of the usual type; the modern style of carpet bedding is also well carried out. Spring bedding is also adopted, and a hundred thousand plants are annually provided. A terrace walk 200 yards in length conducts us past the mansion, and the view from this walk is most extensive. Contiguous to the walk are several acres of open lawn, which slope to the park, and this in turn has a gradual descent to the lake. Beyond the lake is a belt of woods, and beyond the woods a range of hills—bold and extremely picturesque. The west end of the terrace walk terminates in an avenue of Limes. This avenue, which is 400 yards long, merges into a wilderness walk, which extends to the woods beyond the lake.

The kitchen garden is about a quarter of a mile from the mansion. It is three acres in extent and nearly new. It slopes sharply to the south, and overlooks a fertile valley. The prospect over this valley to the distant hills is a splendid

Fig. 86.—NEWTON HALL.

one, is indeed probably unequalled by that from any kitchen garden in the kingdom. The walls are being well furnished with fruit trees, and the sides of the walks are wired for espaliers. Very substantial provision is made for protecting the fruit in this garden from birds, for permanent three-quarter-inch iron bows are affixed over the beds. These bows are 6 feet high for Gooseberries and 4 feet for Strawberries. They have a neat appearance, and nets thrown over them render the fruit safe. The south wall of this garden is covered with glass, the range being 200 feet long and devoted chiefly to the cultivation of Vines, Peaches, and Nectarines. The growth of the Vines and trees is of the most satisfactory kind, and Royal George Peaches were gathered during the summer weighing 10 ozs. Forcing pits are conveniently arranged near Mr. Wardle's residence, and are in full working order. About two miles of pipes are requisite for heating the several structures, a combined saddle and tubular boiler with water bars doing its work efficiently.

The lake has been mentioned, but it demands more particular notice. It is an artificial sheet of water seven acres in extent. It was designed with much taste by Mr. Hancock of Newcastle, who also assisted in the formation of the principal walks and drives; and the work was executed by Mr. Wardle, who was also entrusted with the planting of the estate. Although the lake is still unfinished it has the appearance of

having been formed by nature and to have existed from time immemorial, so skilfully has it been conceived and executed.

But something more remains to be said in connection with that lake. Its owner, a sturdy Northman who has fought successfully the battle of life, is naturally an admirer of those of humble birth who have, equally with the victorious warriors of noble lineage, deserved well of their country. Before him every day he has a cherished memento of an act of true heroism which of its kind is perhaps without a parallel in any country. Do you see the boat moored on the placid waters of the lake? "Yes. What about it?" Look at it again; it is but a rude little cobbie, but is worthy of a second glance. That is an historic boat, the possession of which many might be proud of owning. That boat has not always been moored on the lake at Newton; it has not always been empty; no, it has been battered by the waves of a sea as rough as ever foamed, and has been manned by a form as gentle and brave as ever breathed. It has more than once snatched precious lives from the jaws of death, and deprived the angry sea of its victims. One of the crew of that boat performed a deed—a daring benevolent deed—which excited the admiration of "England and the Isles," which gained for the humble individual who manned it the friendship of a noble duchess, and obtained a personal tribute of approbation from our present Queen. A broken plank from that boat has been divided into

mere fragments, which are preserved by the possessors of them as relics associated with an exceptionally brave and noble act. The act at the time was in all men's minds and mouths, and now it is recorded in books of story for the edification of youth. Do you yet ask "What boat is it?" or do you anticipate its name? Name! it has no name, but that does not matter, for, as many northerners know well, that boat was Grace Darling's. Yes, the veritable craft which on that eventful morning, September 7th, 1838, the intrepid girl—for she was only twenty-two years of age—against a mother's tears implored the aid of her father to rescue the remnant of the crew of the steamer *Forfarshire*, who had given up hope and were clinging in despair to a portion of the ship and the rocks of one of the Farne Islands. By a desperate effort the father was landed on the rock and the daughter was left alone and kept her cobbles afloat by rapidly pushing back from the rocks to prevent the boat being dashed to pieces against them. With much skill and true courage the whole of the wrecked, nine in number, were placed in that little boat and were eventually landed at the lighthouse—the humble but hospitable home of the Darling family. It was this brave act that rendered the boat famous which is now moored on the lake at Newton, and which raised the modest maiden from obscurity to renown. Presents were sent to her from all districts, a public subscription amounting to £700 was presented to her, and it is recorded that the managers of a London theatre offered her £800 for eight nights to sit in a boat on the stage. Her reply to this and similar offers deserves to be remembered. It is to the effect that "she doubted not that if she saw lives in jeopardy she would feel it her duty to do again what she could to save them, but she could not think of exhibiting herself for gain." Well might the public, from the Queen to the peasant, be proud of one so noble-minded, and well may her little boat be so jealously preserved. "It was," says *Arthur's Life of Grace Darling*, published by Adam & Co., Ivy Lane, Paternoster Row, London, "for a number of years in the possession of Mr. George Darling, brother of Grace, of North Sunderland, who seems to have taken some care of it, knowing that the public set a high value on it. Many persons wished to purchase it, but he always refused to sell it till a few years ago. After several applications by Major Joicey he was induced to let that gentleman have it, believing that it would be well taken care of." The sum given for this little craft was a large one. It is a prominent and interesting object in the lake during the summer, and any notice of Newton Hall would be unpardonably incomplete without a brief reference to "Grace Darling's boat."

Such is Newton Hall—its grounds, gardens, and features of interest; at least such as can be remembered of them from a two-hours visit in September, when the pouring rain rendered mental notes the chief resource. Many impressions then gained have doubtless vanished, but not those of the singular completeness of the place and its excellent order, nor of the manifest solicitude of Col. Joicey in providing for the welfare of those around him. A beautiful new church, which has been erected and liberally endowed, also a commodious parsonage and excellent schools, are remembered—a noble gift. New and well-appointed living rooms and library for the under gardeners and model cottages for the labourers are also remembered; and the house—and "home" as well as house—of Mr. Wardle and the kindly welcome met with there are not likely to be forgotten.

Newton Hall is about three miles from Stockfield station, which is reached in about half an hour by train from Newcastle.—J. WRIGHT.

CONIFERÆ AT MELS PARK, SOMERSET.

THE late Rev. J. S. H. Horner was well known as an ardent lover of trees and an enthusiastic admirer and collector of Conifers, with which he commenced forming a pinetum at his seat, Mells Park, Somerset, about the year 1845, in which he planted most of the Coniferæ then known to be hardy enough to withstand the climate of Great Britain. His son, the present worthy proprietor, is an equally enthusiastic admirer of Conifers, and is continually adding some rare or choice specimens to the already rich and extensive collection.

The pinetum occupies one of the hanging portions of the park, with a fine exposure and a good soil; but unfortunately the subsoil is one of the least favourable upon which to establish a collection of Conifers, the large proportion of lime it contains being too great for them to flourish in perfection,

the result of which is that some of the oldest specimens present a rather rusty and stunted appearance. There is a great variety of the choicest Conifers grown, as may be judged from the annexed list, some of which are rather uncommon, and decidedly merit a few remarks. *Pinus ayacahuite* is a distinct and beautiful variety, and is a healthy and thriving specimen. This tree somewhat resembles *Pinus excelsa* in its habit and the length of its leaves, but the colour of the latter is nearer to that of *P. Strobus*. It is, I believe, a very rare specimen—indeed, it is the largest and finest specimen of the kind I ever remember to have seen. *P. romana* is a distinct variety, its globular-shaped head of very dark green foliage being exceedingly striking and conspicuous. *P. monticola* is a beautifully neat and pretty-looking Conifer; it is healthy and thriving. *P. scarina*, *P. Lemmoniana*, *P. Pallasiana*, and *P. pyrenaica* are robust specimens; they are, however, to my mind coarse-growing trees of the *Pinaster* type. *Wellingtonia gigantea* is thriving beautifully in the clay of the coal measures, and the specimens exhibit healthy robust pyramids of foliage.

Probably if the pinetum had been formed on the clay instead of the conglomerate and limestone formation, the Conifers generally would have been much larger and healthier now than they are. *Picea grandis*, *P. cephalonica*, *P. Nordmanniana*, and *P. Pinsapo* are all beautiful varieties, and they are each making a clean, free, rapid growth, and promise in time to make grand specimens.

Abies Albertiana is growing freely; it is the most graceful of all the Spruce species, and it is at the same time a rapid grower and does not possess such a strong tendency to a bushy habit of growth as is exhibited by its congener the Hemlock Spruce (*Abies canadensis*); its foliage, too, is a darker and better green than the latter. *Abies orientalis* is a pretty specimen, and it is a most eligible subject with which to adorn a lawn. Its short, neat, soft green foliage and symmetrical habit of growth are its most distinct and attractive features. *Abies Douglasii* and *A. Smithiana* are of a robust habit of growth, but both are graceful and handsome specimens. *Taxodium sempervirens* is well represented by a fine vigorously grown tree. It would have been probably the tallest specimen in Britain had it not lost its leader for several years; it has, however, now formed a new leading shoot, and promises to thrive well. The three Cypresses are elegant and noteworthy specimens, each presenting a distinct and beautiful habit. The *Araucarias* are good specimens, but are not in a very healthy state. *Fitzroya patagonica* has a very graceful drooping habit, but its foliage presents a rusty appearance; indeed, I never saw a plant of *Fitzroya* otherwise, and I doubt if it is at all suited to our climate, unless in the very mildest and moist localities, with a climate approaching its native habitat on the Pacific slopes of the mountains of Patagonia. There is also a large collection of the newer kinds of recent introduction, many of which give good promise of forming beautiful specimens in the course of a few years. To all lovers of Conifers a visit to Mells Park and an inspection of its fine collection of rare and beautiful trees cannot fail to be both instructive and interesting.—GEORGE BERRY, *Forester, Longleat*.—(*Journal of Forestry*.)

CHAPTERS ON INSECTS FOR GARDENERS.

No. 20.

THE valuable but native Silkworm Moth (*Bombyx Mori*), is in some respects a fair representative of the family *Bombycidae*, sluggish both in the moth state and in the larval condition, our British species of the family generally resembling it in the former respect though not in the latter. Our species are also spinners of silken cocoons; it is not, however, found possible to make their silk available for economic purposes even by carding. That handsome but local species the Emperor Moth (*Saturnia Carpini*), is noted for producing a peculiarly-shaped cocoon, with one end formed on a modification of the lobster-trap plan, so that while the moth can get out its parasitic enemies cannot get in. Sometimes, though, by way of anticipation, they deposit eggs on the caterpillar, which then encloses its foes with itself in the cocoon and comes to an inglorious end. The moth has beautiful eye-like markings, yet one cannot perceive an appropriateness in the imperial name applied to it. Another and still larger species, the Lappet (*Lasiocampa quercifolia*), has, while a caterpillar, curious tubercles along the sides partly hidden by hairs, originating the singular name; and the cocoon, though formed of a kind of silk, assumes a black hue and leathery appearance. That of the Drinker (*Odo-*

nestis potatoria), is also leathery but yellow. The gaily adorned caterpillar is well clothed with hairs, which cover even the feet, and by which the creature bids defiance to our changeful winter, feeding on grasses at intervals from September till May, but is not in any degree prejudicial to fields or lawns, preferring as it does the growth along hedgerows. An exceptional circumstance in caterpillar history is the partiality shown by the caterpillar of *O. potatoria* for the drops of morning dew, which it will sip with pleasure, though most caterpillars evidently entertain quite different opinions about moisture. Damp weather, indeed, appears to be the cause of one of the most fatal ailments prevalent amongst caterpillars, nor do the hairy species, as a rule, escape its influence. In several of these species the moths have been called "Eggers," from the egg-like form of the cocoons; and in one species, the *Eriogaster lanestria*, notable for its gregarious caterpillars, the chrysalis condition has been observed to last two, three, or even five years. Only a single moth in the family (*Bombyx neustria*), is to be reckoned among injurious species, and the favourite food of the caterpillar is Hawthorn, though it is occasionally to be seen on Elms, and on Apple trees in orchards. Feeding when young in companies, these caterpillars scatter about after the last change of skin, and the blue head showing two dark spots with the striped body render it easily recognisable. Rennie has remarked on the circumstance, that a party of them if startled by a noise all jerk their heads in the same direction, an indication that their hearing is good. There are three if not four suppositions as to the meaning of the name "Lackey" applied to this species.

The family of the Cuspidates, also called Pseudo-Bombyces, I take next, though it is sometimes placed after the Geometers, that extensive and well-known family of moderate-sized moths with slim bodies. In appearance the moths of the Cuspidates closely resemble the Bombycids. Though some of them can fly with tolerable swiftness, their figures do not suggest rapidity of motion generally; the singular species denominated "Hook-tips," have, however, slim bodies, and prefer taking excursions by day. The caterpillars may be subdivided into two groups—those that are more or less humped or otherwise eccentric in form, often with, in addition, one or two points at the extremity of the body, of which the Puss (*Dieranura vinula*), is a handsome example; and those of the ordinary cylindrical type, less in number, like that of the Figure-of-8 (*Diloba cæruleocephala*), whose bluish-green cranium has given rise to its very resonant Latin specific name; and, dismissing it in a word, we may note that the caterpillar is one of the host that feed on the Hawthorn, being more conspicuous by the black warts even than by the head, but not abundant enough to be harmful. The small compact cocoon is curiously made-up of gnawings from the bark of the twigs mingled with bits of leaves and silk. Another caterpillar of the customary shape is that which ultimately produces the Buff Tip (*Pygæa bucephala*), an ubiquitous species, which makes itself thoroughly at home in our London suburbs, maliciously anticipating the effects of autumn upon the trees in our parks and shrubberies by baring them of their leaves during July. It is, though, almost the only species of the Cuspidates that can be deemed troublesome to mankind, and in its favour we may state that the caterpillars seldom touch fruit trees, but feed freely on Lime, Elm, Hazel, Willow, and of course Hawthorn. The dull yellow body is marked with bright orange, white, and black, and when in repose, like most Cuspidates, they like to raise the last pair of legs in the air. The head has certainly a "truculent" aspect, and the Buff-Tip caterpillars manifest an exceptional sourness of disposition, for one of them if in the least offended turns its black head sharply and attempts to seize any person or thing within reach. As the chrysalis is simply laid on the surface of the ground without any protection it is easily found by fowls, and Mr. Newman credits these with good service in reducing the number of moths. He says, "These chrysalids constitute a favourite food for poultry, and are sought for with great eagerness. Dame Partlet may often be seen scratching for them in my own neighbourhood under the Lindens." The moth, too, conspicuous by its buff tip, may be readily captured in June ere the eggs have been deposited.

The Puss (*D. vinula*), already referred to, which occasionally excites wonderment when it is seen as a caterpillar on the Poplar or Willow, is not common enough to do damage, though its menacing horns scare-off children who would otherwise remove it from its food. These horns or tentacles are really harmless, but this caterpillar has a means of defence in an acid liquor which it can eject at will from an aperture just

under the head. The tenacity with which the "Puss" and its small relatives the "Kittens" cling to the leaves or twigs is remarkable; they are seldom dislodged by the highest winds in exposed situations, though the caterpillars do not prefer such spots. So tough is the cocoon this species constructs that it will turn the edge of a knife, yet the moth manages to escape from it uninjured. Strangely shaped, again, is the "Lobster" caterpillar (*Stauropus Fagi*), the lengthened second and third pairs of legs, the singular head, the deeply-marked segments, all suggesting a creature which one would scarcely know how to class if the moth did not closely resemble in structure the rest of the family. Several of the Prominent moths have eccentric caterpillars, that of the *Notodonta Ziezæ* for example, doubles itself up in a zigzag manner, which would be prejudicial to its circulation had it any blood. The Willow, Sallow, and Poplar are trees much resorted to by the Prominents, some of which are of such rarity that collectors travel many miles in search of them. These, and others in the Bombycids also, are conclusive instances against a theory lately put forth, that most gaily-coloured caterpillars feed on poisonous plants. The largest of the Prominents (*N. trepida*), occurs in Oak woods, and sometimes flies into houses, attracted by the glare of lights. Honey or other sweets do not, however, hold out any temptation to moths in this family, as the organs of the mouth are very small, and in most species no nutriment is sought by the perfect insect. In the caterpillar of the Great Prominent the circumstance is worthy of notice that we have a display of seven oblique stripes on the sides, as in many species of the Hawk Moth family; but in this caterpillar the stripes slant in just the opposite direction to the uniform mode amongst the Hawk Moths. Each stripe is regularly divided by two tints, half being pink and half whitish yellow. There are also various additional markings on the light green ground colour, so that altogether it may bear comparison with any caterpillar as regards beauty, though to some people it may seem ludicrous to apply that word to a creature which is popularly associated with repulsive ideas.

In the month of May, and again in August, on tapping slightly one of the mixed hedgerows which give a charm to the lanes in most of our English counties, the little moth, *Cilix spinula*, either flies tardily out or falls like a snowflake on the path. This species, also known as the Chinese Character from some peculiar silvery rays on the fore wings that have been fancifully compared to Chinese letters, is the smallest of the Cuspidates, and of very delicate structure. The caterpillar keeps close under the leaves of Whitethorn or Bramble, having a head cleft on the crown, and a body curiously wrinkled and studded with warts; the anal extremity has no claspers, but instead a solitary spike or filament. One group of small moths have so puzzled naturalists that it has been debated whether they are moths or flies. These insects, the Psychids, are now generally placed next the Cuspidates, the males having stout bodies and pectinated antennæ, the wings extending from half an inch to an inch. The females are without wings, and even in the species of the genus *Psyche* minus antennæ and legs, therefore worse off than the caterpillar, for though that lives in a case it can travel about with its domicile from place to place. In or near gardens the case of *P. nitidilla* may be observed during spring on Sallow, Hawthorn, and other low shrubs, this case, however, not being formed of portions of the food plant, but of evenly-chopped bits of grass connected by silk. The moths come forth in June, the females sitting on the outside of the cases upon which they lay their eggs. In *Psyche* the females are, of course, unable to quit the larval case at all. *P. fusca*, which used to be caught at Hornsey Wood in the "good old times," makes a case of variegated appearance as fragments of leaves and grass are crossed ingeniously.—J. R. S. C.

GLAZING WITHOUT PUTTY.

IN answer to "E. W. B.," respecting glazing without putty. I did so glaze a vinery and afterwards a conservatory, and with the latter, which has been erected three years, I am perfectly satisfied. The builder spoiled the roof of the first by neglecting to carry out minutely the instructions given on one point which is absolutely essential to prevent drip. That being attended to in the conservatory the house turns rain like a bottle. The rafters may be from 15 to 20 inches apart and must be formed thus: The groove shown is to convey drip to the face-board and eaves-trough, and the outer edge of the rafter at points marked x must be clear of the glass, or drip

will run down the rafter into the house. It is difficult to make joiners see this, as it involves a little more work and appears so trivial a matter, yet neglect of it will cause all the work to be done a second time, as in my first house.

Fig. 87.

It is not essential that the glass be cut with great exactness, though better that it should be. If there be even space to thrust a knife blade between frame and pane I have found the drops of moisture travel easily from one to another, and a little top ventilation is conducive to the health of plants. Each pane is secured by small indiarubber rollers put on with screws, and three-eighths of an inch thick. The last row of sheets should not rest upon the face-board, but be raised up by a very thin wedge, just to allow the drip free access to the eaves-spouting, and the grooves of the rafters should die out upon the face-board for the same purpose. The front and doors are glazed in the same way as the roof, and a broken pane can be replaced at any time with great ease.—J. W. LAYCOCK.

TEMPERATURE AND HUMIDITY OF THE AIR AT DIFFERENT HEIGHTS.

A MEMOIR on the temperature and humidity of the air at different hours, by Dr. H. E. Hamberg, based on observations made by him during the summer of 1875, at heights varying from 2 inches to 22 feet above the ground, was published recently in the "Transactions" of the Royal Society of Sciences at Upsal. The memoir is a valuable one, and is of interest to more than the mere meteorologist, it being evident that the inquiry is so handled as to bring it into close connection with such difficult questions as convection currents in the free atmosphere and the diffusion of vapour through the air.

In clear weather the temperature of the air nearest the surface was lower than that above it, from two to three hours before sunset to at least two or three hours after sunrise. At all the six heights the temperature fell to the minimum at the same hour—viz., about 3 A.M.; but while it continued from this time to rise steadily at all the heights, the lowest temperatures continued to be observed in the strata nearest the ground till several hours after sunrise. From this remarkable result Dr. Hamberg concludes that the increase of temperature in the lower strata of the air in the early part of the forenoon is not an immediate and direct consequence of the heating of the ground, but is rather to be attributed to the absorption by the air, or more strictly by its aqueous vapour, of the heat received from the sun's rays or reflected from the ground.

Over uneven ground covered with vegetation the temperature near the surface is generally higher over those parts of the field which rise above the general level. Thus even slight elevations of only 1 or 2 feet have the air immediately resting on them often 2° higher or more, whilst on the other hand a trench or depression 1 or 2 feet below the general level has the air resting on it often 2° or more lower than the air over the level portions of the field, a result of considerable practical importance in agriculture and horticulture.

The latent heat set free on the formation of dew appears from the observations clearly to retard the lowering of the temperature, but not to the extent which might have been expected. When, on the deposition of dew, the temperature of the air near the surface has fallen below 32°, as soon as the dew is congealed into hoar frost the temperature of the lowest stratum of air in contact with the ground instantly rises to 32°; but at the same time the temperature of the air higher up steadily remains lower than 32°.

The absolute humidity of the air on clear nights on which no dew is deposited decreases from the ground upwards, just as happens during the day; but on the other hand, with dew the humidity is least nearest the ground, and increases with the height; and this influence of dew in diminishing the humidity extends upwards to at least 22 feet, the height to which the observations were carried. Since his observations clearly show that the absolute humidity begins in the evening, to diminish near the ground before any dew is observed to be

deposited, and also diminishes at all heights on those nights during which no dew whatever is formed, Dr. Hamberg is of opinion that the diminution of the humidity of the air during night is to be sought for in other physical causes than the deposition of dew.

Several of the points discussed will doubtless be made subjects of further investigation by others. In all cases it is most desirable, indeed absolutely necessary to a critical valuation of the observations, that the authors give woodcuts and descriptions of the exact position and mode of protection adopted in the case of each thermometer employed in the observations. For such refined inquiries the method of observation must necessarily be a refined one; in other words, such as will certainly secure the necessary comparability among all the instruments.—(Nature.)

NOTES AND GLEANINGS.

At a general meeting of the ROYAL HORTICULTURAL SOCIETY held on Tuesday the 4th inst., G. T. Clark, Esq., V.P., in the chair, the following candidates were duly elected Fellows—viz., Mrs. Bostock, Lady Canningham, Mrs. Going, Mrs. Robert Maxwell, Sir George Meyrick, Bart., R. J. Pettward, F. J. Smith, Mrs. D. Hall Willats. Mrs. F. Gallup and Mrs. Lewis were admitted guinea members.

THE Veitch Memorial Trustees at a meeting held on the 4th inst. confirmed their provisional resolution to place a VEITCH MEMORIAL MEDAL with a prize of £5 at the disposal of each of the under-mentioned societies for the several subjects specified, it having been ascertained that the exhibitions in 1878 of the respective societies will take place at a period of the year when these subjects can be produced.

MANCHESTER, June 7th.—For the best specimen Orchid in bloom.
YORK, June 19th—21st.—For three bunches of Black Hamburg Grapes.
CLAY CROSS, August 13th.—For a dish of Peaches and a dish of Nectarines.
HEREFORD.—For twelve cut blooms of the best new Rose sent out within the last five years.

EXETER, August 23rd.—For a collection of twelve kinds of vegetables, distinct.

BRIGHTON, in June.—For one bridal and one ball-room bouquet.

WOODBIDGE, July 11th.—For three stove or greenhouse plants in bloom, distinct.

READING, May 23rd.—For three stove or greenhouse plants in bloom, distinct.

DUBLIN, Royal Horticultural Society of Ireland, in August.—For three bunches of Muscat of Alexandria Grapes.

BELFAST.—For twelve cut blooms of the best new Rose sent out within the last five years.

The prizes are to be open to competition amongst *bona-fide* gentlemen's gardeners eligible to compete at the several shows, and the subjects exhibited are in all cases required to display superior cultivation.

AMONGST berry-bearing plants for stove and greenhouse decoration during the winter few are more effective than well-grown examples of *ARDISIA CRENULATA*. The system adopted by those who grow this plant largely and well is to raise seedlings, and, when large enough, to cut off their tops and strike them in a close well-heated frame or propagating house. When rooted the plants are grown rapidly and close to the glass, and they eventually flower profusely and produce their brilliant berries in great abundance while the plants remain in a dwarf state. They continue ornamental for many months, and are admirable for vase and room decoration.

THE new ZONAL GERANIUM DR. JOHN DENNY, raised by J. Sisley of Lyons and exhibited by Mr. Cannell, has, writes a correspondent, quite set at rest the probability of a blue or purple variety being produced, and great honour is due to its distinguished raiser. Besides its prevailing purple colour the base of each petal is bright crimson tinted with orange, which gives it a striking appearance; this, together with its fine trusses, free growth, and shape of blooms, renders it one of the best for pot or house decoration.

THE glaucous form of *PICEA NOBILIS*, as exhibited by Messrs. W. Paul & Son at the Royal Horticultural Society, is extremely ornamental. We have recently seen the same glaucous form of this fine Conifer in the collection of Mr. Richard Smith at Worcester, and of Messrs. Cranston & Co. at Hereford. The grafted specimens of this variety are very distinct, and are much more striking than the usual seedling forms of this popular Conifer: both varieties are, however, sufficiently ornamental to be included in all choice collections of ornamental trees.

It may be useful to note that the striking and floriferous examples of the old and effective *FUCHSIA DOMINIANA* which

were exhibited by Messrs. Veitch at South Kensington last week had been potted from the open ground. The cuttings had been struck in March and eventually planted out. In the autumn when the flower buds were showing the plants were potted in rich soil, and they will in all probability continue flowering throughout the winter. Since this simple mode of culture has been proved so successful, this distinct and highly ornamental variety should become very popular for decorative purposes during the late autumn and early winter months. The beauty of its bright trumpet-shaped flowers is enhanced by the rich dark foliage, which is much finer than that of most other Fuchsias.

— The great Exhibition now being held in the Agricultural Hall, Islington, is highly worthy of inspection by all who are interested in the cultivation of the soil. Besides the live stock and implements for the farm, garden, and household the remarkable collections of roots exhibited by Messrs. Suttons, Carters, Webb, Harrison, Gibbs, &c., cannot fail to possess interest to many of our readers who are more or less identified with agricultural pursuits.

— THE ADULTERATION OF SEEDS ACT is evidently not to be any longer regarded as being inoperative. A firm of seedsmen composed of Messrs. Walter Jacob Maas, James Frith, and Alexander Frith, were summoned before the Magistrate at Southwark Police Court on the 10th inst. for selling to Mr. Alexander Francis 2 cwt. of White Clover seed dyed with intent to defraud him. Evidence having been given of the purchase of the seed, Mr. Bernard Dyer, F.C.S., member of the Society of Public Analysts, proved the existence of a practice for rendering worthless seeds saleable by subjecting them to sulphur fumes, which changed the appearance of the seed. Mr. Edmund Clarke, who appeared for the defendants, contended that under the wording of the Act no illegality had been committed. Mr. Benson, the Magistrate, regretted that such appeared to be the case and felt bound to dismiss the summons, but offered to state a case for appeal to the Court of Common Pleas. It is clear that those who now tamper with seeds are playing a dangerous game, and they cannot pursue their nefarious practices with impunity. If the weakness of the Act has been pointed out it can only have one result—the Act must be amended.

— We have received a pamphlet entitled "THE POTATO DISEASE, illustrated by photo-micrography," by Robert Bell, M.D., &c. It comprehends much information. We make two brief extracts. "There can be little doubt in the fact that a great amount of Potato disease is due to bad situations being chosen for the crop, and sowing it in other instances in soil which is rendered unfit for its culture, either by being naturally too heavy or badly drained. . . . What are the means which should be adopted to preserve our Potato crops? First, it is necessary to select a light soil so that the tuber may be kept as dry as possible, a condition which is essential to the health of the Potato. When the ground is heavy, and consequently retentive of moisture, the Potato becomes watery and unhealthy, and therefore more liable to become a prey to disease. Secondly, Potatoes in a moist climate like ours ought always to be planted on an elevation, never in a hollow. Every sunbeam should be able to shed its influence on the plant, and every breath of wind ought to be able to find access to its leaves and stems. Another most important consideration which requires the Potato cultivator's most watchful care, and that is to be certain that he procures his seed from an entirely different locality from that in which he intends planting his crop. It is most essential that the seed be as new to the soil as possible, as by this means a much more vigorous plant is reared, and therefore it will be less prone to disease. Too much cannot be said upon the error of planting crop after crop from seed taken from ground in the immediate neighbourhood. It is sure to degenerate, the weakness of the parent becoming intensified in the offspring. The question is often asked, How is it if a fungus, which you maintain is ever present, be the cause of the disease, it did not manifest itself till 1836? I believe not renewing the seed sufficiently often has a most important predisposing cause, another I believe to be the overcrowding of the plants. It may be asked with equal force, How was it that certain diseases did not develop their symptoms in man before the dates which history tells us were the periods when they first unmasked themselves? A like answer may be given—the social and sanitary conditions of man had so far deteriorated that favourable conditions for the generation of the various specific diseases sprang into existence, and it is—as

far as science can prophesy—certain that if we undo all the evils which have provoked the various zymotic poisons into activity, they will recede into the passive existence which enveloped them in the past. Keeping the essentials just mentioned before us we should endeavour to plant the rows in the direction of the prevailing winds, and they should be very wide apart, at least twice the ordinary width, so that a row of Turnips could be sown alternately with a row of Potatoes. This, I am convinced, would tend very much to preserve the Potato crop. The two crops could be grown together with great advantage to each other. But suppose the disease has manifested its presence on the plant; then immediately every stem should be cut off close to the earth, and the cut surfaces sprinkled with lime or soot."

— MR. S. PARSONS, writing in the *Rural New Yorker* on WINTER PROTECTION, remarks—"A strong temptation to cover up plants for winter presents itself to the inexperienced during the first cold snaps of November. The ground is firmly frozen, and now it seems natural to suppose the time for winter covering has arrived, but there never was a greater mistake. Such early spells of cold usually last but a short time, and may be succeeded by much warm weather, thus exciting the sap of the plant under cover, and thereby exposing it to injury from a succeeding heavy frost. The hardening-off process is as necessary to the plant in the open ground as under a proper system of greenhouse culture. Several really cold periods in early winter brought to bear on the uncovered plant serve to prepare and adapt it for the endurance of subsequent hardships. Little injury, moreover, occurs from cold in December to any tolerably hardy plant. It is the proper season of rest, and the diminished power of the sun works the less damage because dawn and midday present no such violent contrasts of temperature as are wont to appear in early spring. A large majority of all plants that die from the effects of cold, die, therefore, in March and April, and hence the danger of removing covering too early in spring."

— "F. W. B." writes in "The Gardener" on VEGETABLE MARROW PRESERVE:—"When in a provision shop, a few evenings ago, I observed that several poor persons bought in small quantities a kind of mixed preserve of a questionable character, which, although flavoured with essence of Raspberry, looked as if compounded of Beetroot and molasses: this was purchased freely at 6d. per lb. Acting upon this hint, I determined to do my best to arrive at some near estimate of the cost of manufacturing fairly good Vegetable Marrow preserve. The constituents were as follows:—A good-sized Marrow, costing 3d., when peeled and freed from the seed vessels, gave 5 lbs. of usable material; to this were added 3 lbs. of loaf sugar at a cost of 1s., and a Lemon and spoonful of ground ginger at a cost of 3d., making a total cost of 1s. 6d. This mixture, boiled nearly two hours, gave us a most pleasant and wholesome preserve, just $5\frac{1}{2}$ lbs., at a cost of about $3\frac{1}{2}$ d. per lb. Of course this does not include labour or firing, but that in the present case was almost too small to be included. What I want to show, however, is this, that I can manufacture an article such as my family and friends pronounce to be excellent for $3\frac{1}{2}$ d. per lb." The Marrows should be nearly full grown for preserving.

NOTES ON VILLA AND SUBURBAN GARDENING.

CHRYSANTHEMUMS are favourite flowers of many a villa gardener, and are admirably grown by amateurs in the vicinity of the metropolis, indeed London may be said to be the head quarters of this queen of autumnal flowers. The well-known and far-famed Temple Gardens give an impetus to Chrysanthemum culture, and the numerous exhibitions springing up around us speak well for the increasing popularity of this useful flower, which is in beauty at a time when flowers are becoming scarce. It spans the passing season of outdoor bloom with the forcing season of indoor display, and makes our conservatories for six weeks exceedingly attractive; indeed there is no other flower which repays the cultivator better than the Chrysanthemum.

Now is the time to commence operations for a good display of well-formed flowers next autumn; but cuttings can be struck at any time from now till May and make useful plants, yet those taken off now while they are short and stubby, and inserted in light sandy soil around the sides of some 60-sized pots, will strike very readily. When sufficient are taken off the old plants can be either planted out or thrown away. The pots will be found useful for other plants, and the stock is reduced to the smallest possible space.

The best cuttings are those thrown up from the base of the

plant, and they can generally be attached with a small particle of root, which is an advantage. If these cuttings when inserted are placed in a cold frame they will keep quite healthy and very few will damp off. We prefer at this season of the year placing them in a cold frame rather than inciting them by fire heat, unless it be for the purpose of growing very large specimens. After the cuttings are inserted they should be kept tolerably close, but afterwards air must be given on all favourable opportunities, and on very fine days removing the lights altogether. Protection is required during frosty nights, otherwise the soil would become frozen and would injure the tender rootlets. The after-treatment of this flower will be referred to in future calendars. The following forty varieties are the best both for exhibition purposes and home decoration. *Incurved*—Antonelli, Alfred Salter, Aurea Multiflora, †Barbara, Beethoven, Bronze Jardin des Plantes, Beauty of Stoke Newington, Cherub, †Eve, †Empress of India, †General Bainbrigge, Guernsey Nugget, Gloria Mundi, †Golden Beverley, †Golden Empress of India, †Golden Eagle, Golden John Salter, Doctor Brock, †Isabella Bost, †Jardin des Plantes, †John Salter, †Lady Hardinge, Lady Talfourd, Lady Slade, Miss Mary Morgan, Mr. Brunlees, Mr. Gladstone, †George Glenny, †Mrs. G. Rundle, †Mrs. Dixon, †Mrs. Heale, †Mrs. Haliburton, †Prince Alfred, †Prince of Wales, †Princess of Wales, †Princess of Teck, †Queen of England, Venus, †White Venus, †White Globe, and †White Beverley. The best twenty-four are those marked by a dagger (†). Of the reflexed varieties *Triomphe de Nord*, *Progne*, *Alma*, *Hereward*, *Dr. Sharp*, *Cloth of Gold*, *Christine*, *Crimson Velvet*, and *Julie Lagravère* are all worth growing, and the following will be found the best of the large-flowering *Anemone* varieties:—*Acquisition*, *Bijou*, *Empress*, *Fleur de Marie*, *Prince of Anemones*, *Lady Margaret*, *Gluck*, *Mrs. Pethers*, *George Sand*, and *Louis Bonamy*.

The Japanese section is increasing in favour, and for house decoration and cutting purposes they surpass the incurved varieties. A very good and useful selection is as follows:—†*Elaine*, †*James Salter*, †*Fair Maid of Guernsey*, †*Gloire de Toulouse*, †*Red Dragon*, †*Bronze Dragon*, †*Yellow Dragon*, *The Sultan*, †*The Mikado*, *Garnet*, *Chang*, *Baronne de Prailly*, *Magnum Bonum*, †*Fulton*, †*Fulgore*, *La Nymph*, *Nuit d'Hiver*, *Laciniatum*, *Cry Kung*, *Bismarck*, *Oracle*, †*Meg Merrilees*, *Peter the Great*, †*Grandiflora*, and *The Wizard*. The best twelve varieties are denoted by a dagger (†).

Of Pompons *Antonius*, *Cedo Nulli*, *Golden Cedo Nulli*, *Bob*, *Madame Eugène Domage*, *Marabout*, *Mdlle. Marthe*, *Madame Montels*, *Model of Perfection*, *Miss Nightingale*, *Mr. Astie*, *Marie Stuart*, *Firefly*, *Dick Turpin*, *Miss Julia*, *St. Michael*, *Calliope*, and *White Trevenna* are varieties of proved excellence. —J. W. MOORMAN.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

HARDY FRUIT GARDEN.

We are still working amongst standards and dwarf-trained trees and bushes, pruning them and digging amongst Raspberry bushes after dressing the ground with good manure. Digging amongst the roots of fruit trees requires to be done with care; a careless workman will probably do more harm than good, and one not acquainted with the nature and requirements of the trees or bushes should not be trusted amongst them. Take Raspberry bushes, for instance. A good dressing of manure has been spread over the surface. The rows are 4 feet apart, but round each plant there is a mass of fibrous roots quite close to the surface. Our plan is to take an opening out at one end of the row, and the centre 2 feet is dug out one spit deep, merely stirring up the soil round the plants and mixing it with a little good manure, the largest portion of the manure being buried in the centre. Gooseberry and Currant bushes also require a good supply of manure, and it ought to be dug in much in the same way. If the Gooseberry bushes were infested with the caterpillar during the growing season it will be necessary to pare off about 3 inches of the surface of the soil under the bushes, and bury it about a foot deep in the centre of the rows. The soil from the bottom ought to be spread under the bushes, and this, of course, will be free from eggs of the caterpillars.

When the weather is favourable the work ought to be proceeded with on walls. A man may be able to prune with a pair of gloves when the weather is cold, but nailing should not be proceeded with when the thermometer falls below the freezing point. Plum, Pear, and Cherry trees are done first. It is best to attend to such work as soon as possible; indeed all sorts of work require to be brought forward, whether it is nailing, pruning, or digging; severe weather may set in and put a stop to the whole until February or March.

PEACH HOUSES.

The late houses may be prepared for starting by taking the trees down from the trelliswork and tying the growths up in bundles. This is done purposely to prevent the flower buds from being rubbed off when the glass and woodwork are being

cleaned with weak soapy water. We have seen gardeners doing such work with old shading or other rags that come first to hand; this is not economy even, and the work cannot be well done. The best material to use is washleather, and the wood or glass can be rubbed clean and dry with this as the work proceeds. The walls should first be well scrubbed with clean water and then be done over with limewash. We have used for this two parts of lime fresh from the kiln and one part of flowers of sulphur; it should be laid on while hot, as in this state it is sure to effectually destroy eggs of insects or the insects themselves, which find a lurking place in the crevices. After the house has been made clean the trees must be dressed, and it may even be necessary to wash them carefully first, especially if there has been any scale upon the young wood. This pest can easily be removed by washing it off with a sponge. The mixture that we use to dress the trees is composed of sulphur dissolved in soapy water, and to it is added a little tobacco water; a large wineglassful to a quart is sufficient, as the stuff is strong. In applying it to the main branches it should be scrubbed well into the interstices of the bark; the small branches containing buds should be done carefully, as the buds are easily rubbed off.

The border next claims attention, and our experience goes to prove that a hard surface is better for the trees than a loose one, but it depends something on the character of the soil whether it becomes firm or not. In a loose soil no roots will be found close to the surface, while a firm surface composed of good clayey loam will be found interlaced with healthy roots. If there are plenty of healthy roots near the surface we remove as much of the soil as possible without doing them any injury, then place a layer of rich decayed manure about 2 inches over the surface, and over this some good turfy loam. We have previously alluded to the danger of allowing the borders to become too dry, as the blossoms will probably drop. Another cause of the flowers falling off instead of setting is the mixture with which the trees are dressed being too strong. What would not cause the least injury to Vines would utterly ruin the prospects of a crop of Peaches.

GREENHOUSE AND CONSERVATORY.

The *Chrysanthemums* are still beautifully in flower, and they will probably keep the house gay until the new year. They were later to flower, and the blooms are lasting longer in beauty this year than usual. The usual time to take cuttings is in the spring, when they are growing freely; the succulent tops are cut off and the cuttings inserted in small pots; they will be rooted plants in a few days if the pots are placed in a frame with a brisk bottom heat. Another plan is to place the cuttings in cold frames, merely plunging the pots in cocoa-nut fibre refuse. We have seen many good flowers in the neighbourhood of London during the last dozen years, but we are not sure that they have been superior if equal to those grown in Scotland twenty years ago by Mr. Laing of Dysart, Fifeshire, now of Stanstead Park, Forest Hill. Mr. Laing's plan was to insert the cuttings in December and strike them in cold frames; he placed one cutting in the centre of a 60-sized pot, and when they were well rooted, say in April, he potted three plants in a 15-inch pot and took about three flowers from each plant. His compost was good turfy loam and decayed stable manure with pounded oyster shells, which kept the compost open; it is also a good plan to drain the pots with oyster shells.

Hardwooded plants that flower at this season are very valuable. Camellias, of course, are in all collections of greenhouse plants, and if they have been treated as recommended in summer there will now be plenty of flowers. The Double White and Fimbriata are the finest and most useful of all, but many of the coloured sorts are used where the white would not answer. It may be necessary to look over the plants to wash the leaves if they are black on the upper sides with a gummy substance, caused by scale; this is easily removed by a sponge and soapy water.

Epacris of sorts are extremely useful from now till March, and even to midsummer, but by that time other flowers are plentiful, and they are not held in so much esteem. We have *E. miniata splendens* and *E. Eclipse* in flower now, and they have produced occasional sprays since midsummer. The rose and white-flowered varieties of *E. hyacinthiflora* are our most valued flowers in winter; but there are many others, each distinct and good in their several varieties. The winter-flowering Heaths comprise the section *E. hyemalis* and the very pretty *E. melanthera*, its graceful sprays of small white flowers are very pretty in small glasses. When time can be spared we are training hardwooded specimens of Cape Heaths and New Holland plants, and no one can attain to success in this who does not study the natural habit of the plants themselves. Our large exhibitions ought to be one place where this could be done, but it is not so; even the first-prize collections have contained plants far too severely trained to show anything like the natural habit of the plants. A good rule to go by is to use as few sticks and ties as possible, and if the plants can be trained into shape without them it will be much more satisfactory.

Stage Pelargoniums are growing freely since they were potted into the blooming pots. We have fastened a string under the

rim of the pots and tied down the growths to this. Where they were too thickly placed they have been thinned out.

FLORIST FLOWERS.

The damp muggy weather is very unfavourable to the growth of Auriculas. The season of rest has come, and the lights are removed on every favourable occasion, and air is also admitted at night. What we want now is a succession of frosts to bring on that natural rest required by the plants. It is necessary to look over the plants once a-week at least and remove the decaying leaves. Now is the time to get rid of green fly, either by fumigating with tobacco smoke or brushing them off with a small camel-hair pencil. Carnations and Picotees require very similar attention, and, like the Auriculas, the plants are making rather too much growth. Occasionally we stir the surface soil of the pots and remove the dead leaves. Considerable care is necessary as regards watering. The plants suffer if allowed to become too dry, and on the other hand if they are saturated with wet the leaves become yellow and the plants will not produce good flowers. Injury is also caused by drip. If this cannot be stopped the plants must be removed from underneath the place, else they will be much injured, probably killed. Pinks and Pansies in beds are growing very freely, and, the ground being saturated with wet, a sharp frost setting in would throw many of them out of the ground, but a mulching of manure prevents this. Choice Hollyhocks in frames are apt to be injured by damp. Mould gathers on the injured portions and spreads rapidly if it is not removed and the decayed part dusted with lime. Dahlias should also be examined to see if there is any damp or mould near the base of the old stem, which sometimes spreads to the tubers. A vigilant eye is required to look over all classes of these plants. Admit air freely on all occasions, and do not allow decay to remain on any plants, nor weeds or green mould on the pots or surface of the soil.—J. DOUGLAS.

TRADE CATALOGUES RECEIVED.

James Dickson & Sons, Newton Nurseries, Chester.—*Catalogue of Forest Trees, Covert and Underwood Plants, Ornamental Trees, Evergreens, &c.*

W. Lovel, Weaverthorpe, York.—*List of Strawberry Plants.* Dicksons & Co., 1, Waterloo Place, Edinburgh.—*Catalogue of Forest and Ornamental Trees and Shrubs, Conifera, Rhododendrons, &c.*

Ant. Roosen & Son, Overveen, near Haarlem, Holland.—*Catalogue of New Gladioli and Dahlias, with list of Miscellaneous Plants and Bulbs.*

Ernest Benary, Erfurt, Germany.—*General Trade Catalogue of Vegetable, Agricultural, Flower, and Tree Seeds.*

Putz & Roes (successors of Ferdinand Jühlke), Erfurt, Germany, and 50, Great Russell Street, London.—*Annual List of Flower, Shrub, and Tree Seeds.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

FRUIT MANUAL (*Rus in Urbe*).—It does not contain the classification.

CHRYSANTHEMUMS (*H. A. L.*).—A list is detailed on page 428.

PEAR LA QUINTINIE (*F. J.*).—We have had no experience of this variety in this country.

CUCUMBERS DISEASED (*G. P., Devon*).—There was not the least trace of disease on the leaves sent. Portions of them seemed to be scorched. We have seen the same appearance on the leaves in winter when the atmosphere was overmoist. If you follow directions in "Doings of the Last Week" you will succeed. Also omit the "weeds and garden refuse" from your compost. The temperature at night should be from 65° to 70°.

CULTURE OF OUTDOOR GRAPES (*G. C.*).—The plan you have adopted is an excellent one. We have seen your plan before, and highly approve of it. Follow it out and let us know how you succeed.

PEARS FOR WALL FACING NORTH-WEST (*Amateur*).—In your district Pears might succeed. Louise Bonne of Jersey and Marie Louise would be the best. The best Grapes for your purpose would be Royal Muscadine and Black Hamburgs.

CULTURE OF BOUTARDIAS (*G. S.*).—These plants are as easily grown as Pelargoniums, and they do well in the cold compost as Pelargoniums are usually potted in. We grow them in cold frames all the summer and remove them to the greenhouse in September. Ours are now in fine flower.

PRIVET HEDGE PRUNING (*M. B.*).—The best time for pruning this hedge is early in the spring.

PINE APPLE CULTURE (*P. A.*).—"The Pine Apple Manual." You can have it free by post from our office if you enclose thirty-two postage stamps with your address.

NAMES OF ROSES (*W. S.*).—It would be of no avail to spell the names phonetically. The only practical mode of ascertaining the proper pronunciation is to apply to an educated cultivator of the flower.

NAMES OF CHRYSANTHEMUMS (*Constant Reader*).—See "Notes on Villa Gardening" on page 461.

MUSHROOM HOUSE MANAGEMENT (*J. L.*).—A steady temperature of 55° is quite enough for Mushrooms in winter, 5° higher is a maximum which we should not much like to reach—certainly not to exceed, and you are probably right in attributing the loss of your young Mushrooms to the parching effects of excessive heat. There are, however, other causes of failure which may or may not have some bearing on your case; neglecting to water till the surface becomes so dry as to throw off the water when it is given; using water of a lower temperature than that of the bed; watering with warm water and letting in a cutting draught of air immediately afterwards, are all fertile causes of failure, especially at this season of the year.

WINTERING SEDUMS (*S. H.*).—The Sedums in your list are quite hardy, and in well-drained, light, gritty soil they may be left fully exposed throughout the year, but in low-lying, damp, heavy soils they are often killed by a few degrees of frost, continued cold and wet being fatal to them. Let this be your guide, and if you have any doubts as to the nature of your soil, give the Sedums the benefit of it by taking them up and planting thickly in coal ashes in a cold frame from which the glass lights are withdrawn except in very wet and frosty weather.

WATERING AZALEAS (*A. A. M.*).—By all means water your Azaleas regularly or you will lose the flower buds, but do not syringe at this dull season of the year. Soot may be used upon the surface of the soil. Cow-dung water does most good if given when the plants are growing freely, and especially when the flower buds start into growth in spring. Now, while the plants are comparatively quiescent, clear water is best.

LIQUID MANURE FOR STRAWBERRIES (*Idem*).—Any rich fertiliser in a liquid state may be given advantageously to Strawberries in pots during the process of forcing till the fruit shows colour, when it must be discontinued. House sewage is one of our best manures, and if enough of it can be had we should really regard an outlay for guano or any similar prepared substances quite unnecessary.

CHILD OF HALE GRAPE (*R. C.*).—It is not a Grape worth growing under glass in this country whatever it may be abroad.

NAMES OF FRUITS (*B. A. H.*).—1, Wyken Pippin; 2, Flat Nonpareil; 3, Yellow Ingestria. (*Edward Sheerman*).—1, Beauchampwell; 2, Hanwell Souring; 5, Hanthouse; 6, Bedfordshire Foundling; 7, Greaves' Pippin.

NAMES OF PLANTS (*F. B. H.*).—It is impossible to name your plant from the specimen sent. (*P. P.*).—1, *Dufoutania spinosa*; other specimens insufficient. (*T. Cleary*).—Apparently *Tradescantia discolor*. (*Suzzer Gardener*).—1, *Adiantum cuneatum*; 2, *Lomaria* sp.; 4, *Peperomia arifolia*, var. *argyrea* (*Bot. Mag.*, t. 5634); 6, *Justicia* sp. (*Stirling*).—*Tricyrtis hirta*. (*Mrs. Day*).—*Lygodium scandens*. It is a native of the East Indies.

POULTRY, BEE, AND PIGEON CHRONICLE.

GUILDFORD POULTRY SHOW.

This Show opened on the 10th inst., and was held in the Green Market. It was a capital meeting, and the quality of the birds was good all round. The pens were Turner's, and the chaff in them, with the feeding arrangements, were all good.

Dorkings opened the list, as in Surrey they should do, and twenty-three pens of more than average quality competed. The cup went to a fine pair of Coloured chickens, good in bone, claws, and comb; second were fine Silver-Greys. In the next class a pair of large Coloured Rose-combs were first; second and third were good Coloured chickens. In Whites the winners were excellent, the cockerel being, we believe, the bird first at Oakham, with a great square-bodied hen. In Cuckoos the first-prize pen was the only pen really Cuckoo-coloured all over, and we do not think they had a white feather in them, while the remainder of the class, though large birds, had a great deal of white in parts of their bodies. In *Cochins* a good pen of Whites were first and pretty Buffs second, while Partridges had third place. Dark *Brahmas* were only moderate, and the Lights, though few, were of fair quality. Of *Spanish* only one pen appeared, which were but of average merit. The Game made a large class, and to the first-prize pen was awarded the section cup. They were smart and stylish Black Red chickens, and cheap at catalogue price of £5 5s. Second were also good Black Reds, and third Brown Reds. In the *French* class a good pair of Crêves were first and moderate Houdans second. The Golden-pencilled *Hamburgs* were excellent, and the winning cockerel of Mr. Cresswell's was of that beautiful bright colour we so much admire, and was mated with a Birmingham winner, and they ran the Game closely for second section cup. In the Variety class Gold Polands were first and Silbies second. The Game Bantams were good. A pretty pen of Brown Reds won first, and Black Reds were second, Piles being third; while in the variety Bantam class Blacks were first and a pretty pen of Nankins second, the cockerel one of the best we ever saw of the breed.

The *Waterfowl* were only of average quality, but the *Geese* and *Turkeys* were excellent. The first adult *Turkeys* weighed 48 lbs., and the second 42 lbs., while in poults the first were 38 lbs. in weight and the second 35 lbs.

The *Pigeons* were all in a mixed class; the quality was extremely good, and forty pens competed. First went to capital White Fantails, the Weymouth winners we heard; second were Yellow Turbids, third lustrous Archangels, fourth Black Barbs, fifth Black Barbs, sixth Black Carriers, and seventh Black Trumpeters, while many other good pens came in for cards.

We thought it an excellent county Show, and hope the attendance on the second day was good.

POULTRY.—DORKINGS.—Coloured and Silver.—1 and 3, O. E. Cresswell. 2,

The Judge was the Rev. R. S. S. Woodgate.

WATFORD POULTRY SHOW.

THE annual poultry Show in connection with the West Herts Agricultural Society was held on the 10th and 11th inst. in the Agricultural Hall at Watford. Few buildings equal this noble Hall for exhibition purposes, and we were glad to notice that the public appreciated the poultry as well as the larger animals, particularly as the quality of the birds shown was decidedly in advance of previous years.

In the *Dorkings* classes the cup for the best pen went to the Rev. E. Bartum; his second-prize birds were said to be those that divided the cup and second prize with Mr. Taylor at the recent Dorking Show; the beautiful condition and fine carriage of the cockerel in the cup pen probably telling with the Judge. In the *Partridge Cochins* classes the first and second-prize birds were very fair, the third-prize poor. In Any other variety the prizes all went to moderate Buffs. A pen of White highly commended were, as we thought, better than the third. The awards among *Dark Brahmas* seemed very satisfactory; in this class some excellent birds were shown. The *Light Brahmas* were a good class, old birds taking the prizes; but Mr. How's pen, No. 32, should have taken second, they being a capital pen of young birds. The *Game* were only moderate, excepting the second-prize birds, which showed the best style. Although not in full plumage, to our mind this pen far surpassed the cup-winners. The *Hamburgh* classes contained some good birds, and the judging was unexceptionable. We could not see, however, why the Judge awarded the champion cup of an agricultural show to a moderate pen of Golden-spangled *Hamburghs* when Mr. Bartum's *Dorkings* were far ahead of them. In such a show *Dorkings* or *Asiaties* should have the preference. The *Bantam* cup went to a pair of White Booted in good condition, but as regards quality we preferred either the first-prize Black Red or second-prize Golden Laced. The remaining classes were fairly filled with good specimens, particularly the *Turkeys*.

The number of entries was 173, seven pens were empty, and, strange to say, no less than 143 were noticed!

POULTRY.—*DORKINGS*.—*Coloured*.—1, Cup, and 2, Rev. E. Bartum. 3, Lord Chesham. *White or Silver*.—1, C. Shewing. 2, Rev. H. Peel. *Cochins*.—*Partridge*.—1, Cup, and 3, G. B. C. Breese. 3, Lord Chesham. *Any other variety*.—1, G. B. C. Breese. 2, J. Long. 3, J. Allen. *Brahmas*.—*Dark*.—1, G. B. C. Breese. 2, J. Long. 3, W. J. Jervis. *Light*.—1 and Cup, G. B. C. Breese. 2, H. Mitchell. 3, J. Long. *Game*.—1 and Cup, G. Bentley. 2, H. How. 3, Lord Grimston. *Hamburghs*.—*Spangled*.—1, Cup, and 3, J. Long. 2, G. Bentley. *Pencilled*.—1, J. Long. 2, S. Robins. 3, Lord Grimston. *Bantams*.—*Game*.—1 and 3, W. Boucher. 2, J. Long. *Any other variety*.—1 and Cup, G. Bentley. 2, H. How. 3, Lord Chesham. *CRAY-COCHINS* or *HOUDANS*.—1, J. Day. 2, J. H. Brooks. 3, S. Humbert. *ANY OTHER BRED*.—1, J. Long. 2, J. Palmer. 3, P. Clutterbuck. 3, F. J. Perry. *Ducks*.—*Aylesbury*.—1, Lord Chesham. 2, P. Clutterbuck. *Rouen*.—1, P. Clutterbuck. 2 and 3, W. T. Eley. *Any other variety*.—Cup, W. J. Lloyd. 2, H. Allen. 3, H. How. *vhc*, P. Clutterbuck. *Geese*.—Cup, J. Long. 2, Mrs. T. Clutterbuck. 3, J. Thurham. *TURKEYS*.—*Norfolk and Cambridge*.—1 and Cup, Mrs. T. Clutterbuck. 2, R. Dickinson. 3, H. How. *Any other variety*.—1, W. J. Lloyd. 2, Lord Chesham. *SELLING CLASSES*.—*Pair of Hens*.—1, G. Bentley. 2, Rev. E. Bartum. 3, G. B. C. Breese. *Cock*.—1, A. Langford. 2, G. Bentley. 3, G. Heap. *Pair of Ducks*.—1, G. Bentley. 2, Lord Chesham. 3, W. J. Jervis. *Drake*.—1, Lord Chesham. 2, G. Bentley. 3, P. Clutterbuck.

The Judge was Mr. E. Hutton of Pudsey, Leeds.

CANTERBURY POULTRY SHOW.

THE annual Show of poultry, Pigeons, and Rabbits was held in the Kent County Pavilion on the 6th inst. and following days. The entries amounted to upwards of one thousand. The prize cards were very promptly placed upon the pens, and the general arrangements, thanks to a thorough business Secretary and to a most indefatigable Committee, were all that could be desired.

Dorkings, Coloured, cock and hen, only four entries. A fine pen, both birds large and well on the feet; they could have sustained their position in a much stronger competition. Second a good pair. *Cockerels*.—First a large-framed bird, but rather leggy and very crooked in the breast; second a compact bird, but behind in size. *Pullets* a fair lot. *Silver-Grey*, cock and hen.—First cock a large bird, good in colour, but bad on the feet. *Cockerels*.—Twenty-four entries. The number surprised us. First a very pretty well-grown bird, a little too long on the legs; second smaller. *Pullets* a good class. Any other colour.

—Good Whites first and second. *Cochins*, cock and hen.—First in some respects a good pen; the hen we thought a little mealy. *Cockerels* and *pullets* moderate classes. Any other variety.—First a beautiful pair of Whites, very pure in colour, but with feathers in great disorder. Second *Partridge* cock, a fair bird; the hen good in size, but behind the modern standard of pencilling. Third rather creamy Whites. *Brahmas*, cock and hen.—First an easy victory, cock grand in shape and colour, and hen well pencilled; next we preferred 122, third, but the cock had an ugly white patch on his breast, which doubtless had its weight with the Judge; second we did not like, the cock was very coarse in the head, and the hen, though well pencilled, was not quite the proper colour. Pen 117, highly commended, we fancied better. *Cockerels*.—First good in shape, well feathered in the leg and beautiful in colour; second in some points equal to the first, but he was a trifle longer on the leg, and upon close inspection we found a shade of yellow in the saddle. *Pullets*.—First good size and well pencilled; second a little light in colour; third darker and well marked, but her neck was heavy in moulting, which gave her the appearance of a twisted hackle. *Lights*, cock and hen, a moderate class. *Cockerels*.—First a good-coloured neat bird, but small; second a similar bird. *Pullets*.—First fair in size and colour, but a little hocked; second will improve. Pen 178, good in many points, but creamy. *Houdans*.—This class disappointed us very much. We have on former occasions seen classes of French fowls at Canterbury equal almost to the Crystal Palace and Birmingham, but since the death of Mr. Dring French fowls, and more particularly *Houdans*, appear to have considerably declined, and it was never more noticeable than at Canterbury; we could not find one good well-matched pen of any size or pretensions. The largest were bad on the feet or had a Dark cock mated with a Light hen. *Créves*.—Only three entries, but better than the *Houdans*. *Spanish*, old birds.—Only five entries, all badly shown, but very even in quality, and had a little trouble been taken in washing the faces of either pen the Judge's decision might have been reversed in its favour. *Cockerels* and *Pullets*.—First, both birds had a good quality of white and were shown in good condition. Our remarks with regard to the former class will apply equally to the remaining birds here. *Game*, cocks.—We did not like the winner—a Black; we thought him a coarse bird, and he appeared very crooked in the neck; second a neat stylish Brown; third very light in the eye. We preferred the second and pens 226 and 227 to any in the class. The latter pen belonged to the owner of the winners, and we think he must have been very much surprised at the choice of the Judge. *Hens*.—First a good Brown, a little rusty on the wing. *Cock* or *cockerel*, Red, bred in 1877, a moderate lot. *Cock* or *cockerel*, any other variety.—First a stylish bird, but a little coarse in tail. *Hamburghs*.—Both good classes. *Bantams*, Black Red.—First a very smart pen. Any other variety.—Fair Piles first, but we liked the third much better; the cock was neater, closer in feather, better head, and finer sickles; the hen was quite as superior. In the Any other variety nicely laced *Sebrights* were first and second, and a good pair of Japanese third. The *Rouen Duck* class was well filled, and the classes for *Turkeys* above the average in quality.

Pigeons.—*Carriers*.—In the cock class the winner had a large eye and plenty of wattle. *Hens*.—A promising young bird obtained the first place. In the class for birds bred in 1877, first a pretty bird, but we hardly thought he had sufficient stuff about him to take the cup over the winning Owl and Dragon. *Pouters* were well represented, Mr. Gill contributing some good specimens. *Barbs* were a poor lot, and the Judge might have with justice withheld all the prizes. *Almond Tumblers* almost as poor as the *Barbs*. *Jacobins* an improvement. *Dragoons*.—Winner a splendid bird, good head, and very grand colour. This with the winning hen were the only *Dragoons* worth notice. *Owls* a capital class. The winner a well-known bird of Mr. Barnes; second and third two capital-headed birds. *Foreign Owls*.—*Charming Whites* were first and second, the former very short in head. *Turbits* were a fair lot, and we thought pen 668 deserved a card. *Fantails* were also a good class. The winners were beautiful in colour and in magnificent condition. The class for *Homing Antwerp* cocks obtained fifty-four entries.

POULTRY.—*DORKINGS*.—*Coloured*.—1, E. Bartrum. 2, E. Rice. *Cockerel*.—1 and Cup, H. Brown. 2, E. Rice. 3, A. Burch. *Pullet*.—1, E. Rice. 2, W. B. T. Pattenson. 3, Rev. J. G. A. Baker. *Silver-Grey*.—1, J. Boulting. 2, Mrs. Wachter. 3, Major W. Plummer. *Cockerel*.—1, J. Boulting. 2, F. Cheesman. 3, Mrs. Wachter. *Pullet*.—1, E. A. Boissier. 2 and 3, Mrs. Wachter. *ANY OTHER VARIETY*.—1, R. A. Boissier. 2, Major W. Plummer. *COCHINS*.—*Buff*.—Cup, Mrs. A. Christy. 2, F. M. Cobb. 3, T. L. Colard. *Cockerel*.—1, E. Burrell. 2, A. Todd. 3, Mrs. W. Paxon. *Pullet*.—1, Mrs. A. Christy. 2, C. M. Stickings. 3, G. Dowker. *Any other colour*.—1, A. E. W. Darby. 2, F. W. Anns. 3, A. Todd. *Brahmas*.—*Dark*.—1 and Cup, H. "B. & W." finds fault with my answers to the questions of "A KILKENNY BEE-KEEPER." He says that "Mr. Pettigrew dismisses the subject with an answer which is by no means complete, and which in fact deals slightly with the whole subject." I am quite certain that the Editors of this Journal, who are the most competent judges in this matter, will not blame me for treating slightly any question they ever sent me for answer, and the "KILKENNY BEE-KEEPER" himself has sent a letter to the Editors in which he very warmly expresses his thanks for the answers. "B. & W." does his best in answering the questions sent to him, and I do my best with those sent to me; but when all is done that we can do there is much left undone, for in every question of bee-management there are

manifold and multiform points and aspects which cannot be compressed in the limited space allowed for our answers and letters. "B. & W." says that I have frequently admitted that I do not understand the management of bar-frame hives. Surely he has misunderstood some statement of mine, and, therefore, unwittingly misrepresented my meaning. For fifteen years I have believed that there is nothing of importance connected with bar-framers which I do not understand.

One point or statement in "B. & W.'s" letter I will now notice rather prominently, for it is of great importance to bee-keepers generally. He says, "Where, as in my own case, the pasturage is scanty and unproductive, such large hives as Mr. Pettigrew's are worse than useless. I have abundantly proved it to be true." In my opinion this statement is made in a reckless manner, and is about as misleading as any statement that ever fell from the pen of a teacher, for hundreds of enlightened apirians in all parts have found that wherever honey can be obtained, large strong hives gather it faster than strong small hives.

Clever and experienced men in the bar-frame school are moving in the right direction by adopting larger sizes of hives. Their intelligence and experience will lead them onwards and upwards. If a large good hive were sent down to the worst district of Somersetshire, and there placed beside one of "B. & W.'s" smaller hives, not one of these enlightened men would believe that the large hive there "would be worse than useless." Fifty reapers can cut and gather together a poor crop of oats much sooner than twenty-five reapers can, and likewise a hive containing 50,000 bees can gather honey in any district faster than a hive containing only 30,000. I repeat what I said before, that wherever large hives are introduced and fairly managed small hives go into disrepute. Many other advocates of small hives at one time have outlived their ancient notions and prejudices, and now keep hives of larger dimensions. Probably "B. & W." will do the same some day. At any rate it is rather late in the day to convince bee-keepers that large hives are worse than useless anywhere. In the bee world there is ample scope for all teachers, for every school of thought and practice. "B. & W." has lessons to give, and I have some to give. Surely we can give those lessons without squabbling.—A. PETTIGREW.

ENLARGEMENTS OF HIVES—TAKE OF HONEY.

I HAVE to tender my thanks to Mr. Pettigrew for kindly answering my questions. His doing so was doubly interesting to me, as I have invented a system of bee-keeping rather similar to his, the main difference between them being, I work mine with frame hives of my own invention. As I am not well versed in the technicalities of bee language, I would feel obliged if Mr. Pettigrew would explain in detail what he means by eking and nadiring. I am also very anxious to know the size of his honey hives, and how many pounds of honey he would expect to get from a strong hive and its swarms in a good season.—A. KILKENNY BEE-KEEPER.

[In my answers to this gentleman's first letter the size of hives was stated. Some are 16, some 18, and some 20 inches wide, and not less than 12 inches deep. Some are deeper than 12 inches. The sizes I prefer are 16 and 18 inches wide and 14 deep. The earliest and best swarms are hived in the larger sizes, and the later swarms in the smaller. In fine seasons for honey the bees require more room, which is provided and given to them in supers, ekes, and nadirs. A nadir is simply an empty hive with a hole in its crown placed beneath a full one. The door of the full one is closed, and the bees soon commence filling the nadir with combs and brood; meanwhile almost all the store honey goes to the top hive, filling the brood cells as fast as they are emptied. By the end of good seasons the nadirs have honey enough stored in them to keep the bees through the winter. In this way both a stock and a honey hive are obtained. If your Kilkenny correspondent will put one of his own frame hives beneath a full one next spring, say about the beginning of May, he will see for himself what nadiring is; and if he put another empty frame hive on the top of both about the beginning of June, he will learn that a hive may be both nadired and supered in a season on the non-swarming system of management. Thus the nadir becomes the stock hive, while the middle hive is taken for honey and the top one for honeycomb.]

Eking is the simplest and most natural because least complicated of all modes of enlarging hives. By eking we enlarge or elongate hives, making them 4 or 6 inches deeper at a time. Riddle rims made the same width of the hives and placed beneath them is eking. Eking in Cheshire is generally called "raising," which is a very descriptive term.

In good seasons good first swarms rise in weight to 120, 130, and 150 lbs. each. Old stocks to 80 lbs. and 90 lbs. each. Second swarms to 60 lbs. and 70 lbs. each. The average weight of a hive, board, and bees, is about 20 lbs., and in estimating the quan-

tity or weight of honey in hives we not only deduct the weight of hives, board, and bees, but allow about 30 per cent. for refuse of the combs. A hive weighing 120 lbs. gross will thus yield 70 lbs. of pure honey, and the 30 lbs. of refuse will yield about 3 lbs. of wax. From 30 lbs. to 40 lbs. of honey from either stock or second swarm we consider a fair average take of honey in good seasons, and about 2 lbs. of wax.

Instead of eking our first swarms in June and July we generally super them, and in this way get about 40 lbs. of honey and a super of 30 lbs. of comb in a honey season from a first swarm. Your correspondent will now see how difficult it is to keep an apiary full of large hives, for in good seasons they become too heavy for stocks—hence they are put down for honey and run into cash. All our hives containing 30 lbs. of honey in autumn are run into cash, and the bees are housed in smaller hives, and fed into stocks at an expense per stock of 5s. each. The average annual profits of an apiary well managed is about £2 per hive.—A. PETTIGREW.]

OUR LETTER BOX.

CANARIES HIGH-COLOURED (E. W.).—Cayenne pepper mixed with their food heightens the colour of the feathers.

PIG MANAGEMENT.—An Old Subscriber would be much obliged by full directions how best to breed the pig, what sort to keep, and how to fatten.

REMARKS.

- 5th.—Damp day, sky a little clearer at times, but rain at night.
6th.—Dark wet morning, finer after 11 A.M., with sunshine; clear starlight night.
7th.—Fine fresh morning, but dull and rainy after 3 P.M.
8th.—Fine dry day, with several hours' sunshine.
9th.—Fine and bright throughout.
10th.—Foggy in morning, dry pleasant day, but no sunshine; clear night.
11th.—Very foggy early, and slightly thick during the day.
Drier, finer, and slightly cooler than previous weeks.—G. J. SYMONS.

COVENT GARDEN MARKET.—DECEMBER 12.

OUR market is now very bare of Pears. The supply of foreign fruit having considerably fallen off we are now feeling the effects of the light crop of home produce. Late-keeping Apples, such as Blenheim, Wellingtons, and Kings, though light, are only making average prices, but late sorts bid fair to fetch their value owing to the indifferent supply of American fruit this year. Late Grapes—such as Alicante, Lady Downe's, and Gros Colman—are in good supply, but Black Hamburgs are nearly out of our market.

From observations taken near London during forty-three years, the average day temperature of the week is 43.9°; and its night temperature 33.4°.

KITCHEN-GARDEN NOTES.

EXCEPTIONALLY cold and prolonged wet weather has not been without its effect upon kitchen-garden crops, all of which have suffered more or less from the inclemency of the weather.

POTATOES were late. The early crops were not particularly large, but good in quality, and free from disease up to the middle of August, after which the murrain became very virulent both in the earlies and second early varieties, they with the late kinds being fully three-quarters diseased, and in some instances, particularly in rich and moist soil, scarcely affording the quantity of sound tubers equal to the seed. The best early was Veitch's Ashleaf, good alike for forcing or outdoors. Early White Kidney (Fenn) is a capital sort, forcing well and cropping heavily. I have tried most early round sorts, but have not found one at all equal to the kidney kinds either in earliness, quality, or productiveness. The best second early was the old Lapstone, it cropped heavily, and was of superior quality. In second early round kinds Rector of Woodstock bore-off the palm, and Snowflake was excellent both as to quality and produce. Those were the best out of over twenty kinds which had been selected from that number multiplied by ten. The kinds named are the very cream of garden Potatoes, quality and productiveness considered.

PEAS.—Late, but excellent up to September. We did not gather until June 28th from William I., an excellent sort, and from Shah, which is a wrinkled Marrow, a few days later. It is a good cropping variety, about 2½ feet high, and of superior quality. First and Best proved very good, and is one of the hardiest and most useful of the first earlies, though for quality I prefer William I. Alpha did not do so well as usual; it, as Mr. Taylor states, is not so hardy as some of the first and second earlies. Dr. Hogg far excelled Alpha as a second early, and proved first-rate. Dr. Maclean did the best of any Pea grown this year, and I esteem it the best of all Peas for quality and crop. Standard gave a heavy crop of well-filled pods of peas of exquisite flavour; but its constitution does not appear of the hardiest. Marvel had a superior crop of the highest quality. That good old sort Veitch's Perfection showed what it could do in a wet cold season; it cropped well and continued bearing for a long time. It is still one of the very best Peas grown. Fillbasket produced an immense crop, but the peas were said to be old when in reality they were not so old as Dr. Maclean and Veitch's Perfection by several days. It does not boil well, and is sure to be rejected when the wrinkled peas of the same age are pitted against it. Prince of Wales (Dwarf Prolific) yielded to none in profusion and quality. G. F. Wilson was not good this cold wet season; its pods were short and badly filled; and Omega was little better. Premier, preceded by Best-of-All, were both excellent. Supplanter produced its immense pods sparingly, and they were not very well filled. Of the above, which

vary from 3 to 4 feet in height, I should select, were I stunted to three kinds, William I., Dr. Maclean, and Omega or Veitch's Perfection, the first two named being the best for producing early and successive crops throughout the season if only two kinds are required. Amongst taller-growing sorts Culverwell's Prolific Marrow grew 8 to 9 feet high, and gave a quantity of its rather short well-filled pods of very large peas of unsurpassed quality. Ne Plus Ultra grew rank; the wet was too much for this very excellent late kind, which was not so good as usual; indeed we ceased gathering peas daily after the 16th of September, and the last dish was obtained on October 12th. The parallel between this year and last as to late Peas was very marked, both summers having been cold and wet.

BROAD BEANS were tardy in growth, and blanks prevailed in the early crops in consequence of the weak germinating power of the seed. The late crops that should have come in in September were failures owing to excessive wet which prevailed at the flowering period. Seville Long-pod must be pronounced a failure in the north; it is a scanty cropper, and its long pods tell very little as compared for productiveness with Early Long-pod, which is quite as early. Monarch is a very superior kind, and a true stock of the Improved Windsor is not yet surpassed.

DWARF KIDNEY BEANS.—With too much wet and without warmth they came to little. Osborn's New Forcing was the best; but when forced, and also for the early crops outdoors, Williams's Early Prolific was good, and produced longer pods. Negro Long-podded fully sustained its character as a good main and late sort, as did Canadian Wonder; but all were very much below an average yield.

RUNNER BEANS were not equal to a quarter of their usual productiveness. Scarlet Champion was surpassed by a new kind which I had for trial with white flowers and white ripe seed. Premier Runner I have grown during several years, and though it is very prolific it is not in favour at table. Mont d'Or Butter Beans have failed; they require a warmer season than has this year been experienced in the north.

CAULIFLOWERS have been superb, none surpassing Walcheren; indeed none other need be grown for affording a succession from June to December inclusive. Veitch's Self-protecting Autumn Broccoli is, however, a hardier and excellent late kind.

CABBAGES.—It has been a good season for all these. They started slowly, but afterwards grew luxuriantly. Heartwell Cabbage sown in spring has given and is giving grand heads now, very tender and deliciously flavoured. There will be no scarcity of Winter Greens, and though Savoys may be somewhat small in size they are very firm. Hill's Incomparable, and Wheeler's Cocoa-nut, with Heartwell (Carter), I consider the best of Cabbages for spring, summer, or autumn. In Savoys Drumhead is good, but not so hardy as Green Curled. Brussels Sprouts are shorter than usual, but the sprouts are unusually compact. The kind grown is Scrymger's Giant. I sow

late in March or early in April where the plants are to remain, thinning them out to the required distances. The plan answers equally well also for Savoys, the plants being much sturdier from the first, and receive no check by transplanting.

BROCCOLI.—The heads were poorer last spring than we ever had them; they were also late and came in "a glut." I have abandoned the culture of "winter" Broccoli, not having had a head but what was damaged by frost for years, for the early winter sorts do not head with me until late winter, and with Cauliflower or autumn Broccoli, Veitch's Self-protecting being first-rate if lifted when the heads are 3 or 4 inches in diameter and planted in frames and protected from frost, continuing until very nearly the time the spring Broccolis come in. The kinds grown are Veitch's Spring White, a capital kind, having very compact medium-sized pure white heads, followed by Cooling's Matchless, Leamington, Lauder's Goshen, and Sutton's Perfection, all first-class. I should not like to dispense with any of these, but Leamington is perhaps the least satisfactory. The plants are this year not strong. I have not laid the plants for many years. None have been "legged" by frost, which may be due to the saline manures applied—nitrate of soda, which is also a powerful agent against slugs; 1 lb. is a sufficient application to a square rod—80½ square yards.

CARROTS.—These have, as they have ever done with me, grubbed, though I have used wood ashes, and soot and lime plentifully, and have also grown Onions in the Carrot beds. They are usually attacked at thinning time, when I usually dress with soot, evidently too late, as the eggs of the fly are then deposited, the grub being at work shortly afterwards. The wood ashes are placed in the drills at sowing time. A wineglassful of paraffin well stirred into three gallons of water, let stand forty-eight hours, and then having the oil skimmed off, I find to be a good preventive both of grub in Onions and Carrots, applying the water with a rose watering-pot when the plants have two blades or two leaves besides the seed leaves, and again just before or immediately after thinning. The French Forcing Carrot is the best for frames, Early Horn for use in summer, and Intermediate Scarlet for autumn and winter. Red Surrey is first-rate for deep soils.

PARSNIPS and BEET.—Both crops are fine. There is no better Parsnip than a good stock of Hollow-crowned. Of Beet Dewar's Dwarf Red is early and of good form, size, colour, and quality. Some others are higher-coloured, but they are not so uniformly good. Salsafy and Scorzonera are smaller than usual and much forked. Jerusalem Artichokes are very uneven in form. Turnips are excellent, especially Early Snowball, Early White Stone or Six-weeks, and Golden Ball. Vegetable Marrows were practically a failure. Long White was no better than the Custard. The season has been too cold and wet for them.

CELERY is shorter and smaller than might have been expected, but the quality is good. Sandringham or Incomparable Dwarf White is the best white, and remains longer in use than any other sort. Leicester Red (Major Clarke's) is the best red, but it is not so good a keeper as Williams's Matchless Red.

LETTUCES were probably never finer. Early Paris Market is a first-rate Cabbage Lettuce for frames and for early use, coming in before any other by several days, and appears to be not only earlier but hardier. Neapolitan is the finest of all the Cabbage kinds for summer. Stanstead Park is the best Cabbage sort for standing the winter. Of Cos varieties the old Bath or Brown Sugarloaf is good, and for frames is unequalled, also for early summer use. Hicks' Hardy White is a good kind for either summer or winter, but is surpassed in summer by the Alexandra White Cos, which is simply a good stock of Paris White.

ENDIVE.—This is not so fine as usual. The Round-leaved Batavian and Green Curled are the best. The plants have often given so much trouble in covering and uncovering with protecting material that we now plant in frames and cover with dry leaves, which excludes frost and light. The lights are used to throw off wet. A foot thickness of leaves will keep off any amount of frost and cause the Endive to blanch perfectly.

CHICORY.—I find it better to leave the roots in the ground until wanted, as when they are taken up and stored in sand growth takes place in mild weather, whereas by leaving them in the ground we take up as wanted without any loss, and plant in rich soil in a dark place. In a Mushroom house the heads are fit to cut in about three weeks. Witloof is the same as Large-rooted Chicory; in fact we have both sorts, and no one can tell any difference between them. The well-blanchd heads are admirable for winter salad.

Of **RADISHES** none are more esteemed than French Breakfast, which is excellent for forcing; so also is the White Forcing Turnip (Sutton's). Wood's Early Frame is all that need be grown of the long short-tops for frames and early produce, but in summer it is superseded by Long Scarlet.

TOMATOES.—Plants out of doors have entirely failed. Some in cold pits had the disease badly, and others in a cool house were also infected, but others, again, in a warmer and drier house were not contaminated, though the plants were placed in contact with fruit blackened by the disease. Orangefield Dwarf is fine for pots, and Hathaway's Excelsior for planting out against walls. Carter's Greengage is the best of the yellow-fruited sorts.

ONIONS have been a good crop and are keeping well, except Danver's Yellow, which does not keep well with me, nor does it crop so well as Reading, which, with White Spanish, are the best whites. There is no difference in appearance between Brown Globe and James's Keeping, yet the latter will keep much longer than the former, though both are good keepers. Leeks have done grandly. Carentan is the best; it is an improved Musselburgh.

ASPARAGUS came up very weakly. Some of the heads were damaged by frost, the supply having been not only scant but of short duration. Connover's Colossal was very much better than the old variety, which will soon be superseded by it. Artichokes (Globe) have been excellent. The old plants continued producing heads late in November. The spring-planted suckers were not profitable. Summer Spinach was good. The winter crop is very thin and not at all promising. Seakale has made good growth and ripened off well. After two seasons' experience of Fern-leaved Parsley I find it superior to any of the curled sorts both for culinary and for garnishing purposes. Mushrooms, as regards fields, have been a blank. Beds in the Mushroom house are cropping well and are producing very fleshy Mushrooms. Rhubarb excellent; that now forced is very strong for the time of year. St. Martin's is the best for forcing and early. Monarch is the largest sort and is of very good quality.—YORKSHIRE GARDENER.

CHRISTMAS DECORATIONS.

GLADLY do I sit down to pen a few hints on Christmas decorations in response to an appeal from a correspondent who has annually to decorate a dining-room and a church, for it is a subject to which the heart warms, beset as it is with pleasant associations and cheerful reminiscences; not, alas! without a tinge of sadness, the mind involuntarily taking a retrospective glance to scenes of brightness long since passed away and dear friends gone to the "land of the leal." How the sad roll of the departed lengthens with every year of one's life! Christmas come again? So it is. Soon will the little folks be declaring that it is quite the best Christmas they have known, and no doubt it will bring with it its own peculiar delights. Let me therefore not stay to moralise, but turn forthwith to the assistance of "S.," who in the dining-room appears to have hitherto confined his efforts to wreathing the pictures with evergreens, and who this year wishes to take a somewhat higher flight.

Now, let us suppose we have such a room having pictures hanging upon its walls with certain intermediate spaces, and to which we wish to impart a festive appearance with simple and inexpensive materials, and we might treat it very successfully in this way: Between each pair of pictures exactly midway we would fasten to the wall a bracket a few inches higher than the bottoms of the picture-frames, placing upon the bracket a vase filled with foliage of Iris foetidissima intermingled with pods of its scarlet berries drooping down from the long flexible stalks. Wreaths of Ivy should then be made to sweep downwards from each side of the bracket in a bold graceful curve, meeting another wreath from the next bracket in the centre of the bottom of the picture-frame, where three or four shoots of Ivy should hang down in the manner of a tassel. Plants in pots could of course be used instead of vases, and such other evergreens for the wreaths instead of the Ivy as taste or fancy may suggest. Failing the brackets a cluster of berried Holly might be used, but the effect would be neither so light nor elegant.

Church decoration should, I think, be confined to the embellishment of the pulpit, reading desk, altar, font, pillars, lamps, window-sills, and perhaps some portion of the walls. The seats should be left untouched, as also should memorial tablets and monumental tombs. I am fully aware that here

I am upon a delicate and vexed subject, and will only say generally that it appears to me desirable in this matter to strive for a happy medium between the florid embellishments of an extreme ritualism and the vulgarity of a certain old sexton, whose highest efforts never reached beyond sticking branches of Holly into holes made in the tops of the partitions and doors of certain old-fashioned square pews, and in throwing a few pieces more Holly upon the window-sills.

Most pulpits are panelled, and I know of no better way of treating them than to put a neat wreath of evergreens around each panel with a sacred symbol or monogram upon the panel itself. I have seen some very pretty wreaths composed of Holly, Laurustinus, sprays of Conifers, various berries, and white and yellow Everlasting Flowers. The best shrubs for really choice wreaths are berried Holly and the rich golden yellow variegated variety Golden Queen, *Cotoneaster Simondsii*, *Garrya elliptica*, *Laurustinus*, *Arbutus*, Ivy, *Berberis*, sprays of the scarlet Dogwood, *Osmanthus*, *Skimmia japonica*, *Pernettia angustifolia*, *Euonymus radicans variegatus*, and Box. Moss may also be used and Fern fronds, such as *Blechnum boreale* and the common Oak Polypody, so pretty at this season of the year with its yellow fructification, and *Iris foetidissima* may also be turned to account for this purpose. There is an indescribable charm about a well-made and skilfully-arranged wreath which can only be imparted when the makers possess refined and cultivated tastes; and I would counsel those who are sensible of a deficiency in this respect to avoid all ambitious attempts at startling effects or elaborate embellishments. Rather let your materials be few and simple, and also let that be the characteristic of your decorations, for then you will probably succeed in pleasing in a matter wherein you cannot reasonably hope to do more.—EDWARD LUCKHURST.

JUDGING ROSES.

In the peculiarly interesting report of the meeting of the National Rose Association on December 6th allusion is made to the desirableness of formulating rules for the guidance of judges. It is much to be desired. Every man fancies he is a judge of wine, a judge of theology, and able to judge Roses.

Judging from complaints in print, the office is sometimes accepted somewhat lightly and unadvisedly. At the large shows, however, and where well-known names are in office, it is more than foolish to make any question. I do not write as a judge. "I am not the Rose," as the French proverb says, "but I have lived near it." I have often been adjudicated upon, and I can only recollect two or three instances in which my partial opinion and that of two or three friends differed from the decision, and then the doubt was at once removed on asking for an explanation. After a certain time the faculty becomes almost an instinct. It is not often that boxes run each other very close; if so, I have observed one way is to pick out the weak points first of all. Whoever has fewest inferior flowers wins. Another plan is to give marks, and this I apprehend, in connection with the other, is the one generally adopted.

Mr. Shirley Hibberd, in his "Amateur's Rose Book," lays down the canon, "No new Rose ought to be certificated unless it is 1st, distinct; 2nd, of perfect form; 3rd, of good substance of petal; 4th, each petal shell-shaped and egg-shaped." The same principle will apply when compared in close competition. Form, colour, size, are the three necessary qualities according to Mr. Michel. Canon Hole, in his royal "Rose Book" decrees much the same. "Show Roses require beauty of form, beauty of colour, and that the Rose having both these qualities shall be exhibited in the most perfect phase of its beauty and in the fullest development to which skill and care can bring it." "An exhibition Rose should have," writes Mr. A. H. Kent (a name which many have misread of late from the Rose pages of our Journal)—"1, Richness or delicacy of colour; 2, Symmetry in form; 3, Size, in connection with 4, Vigorous habit; 5, Free-blooming qualities."

But perhaps Mr. T. Moore, F.L.S., in an interesting paper "On Judging New Plants" has given the fullest directions of all. Taking one hundred marks as indicating the highest degree of excellence, he would assign: 1, Form, 15 points; 2, Substance, 15; 3, Smoothness, 15; 4, Colour, 10; 5, Fixity of colour, 10; 6, Proportion, 10; 7, Size, 10; 8, Distinctness, 10; 9, Novelty, 5.

I do not myself attach much importance to the idea that even first-class judges have their hobbies and sometimes ride them rather fast. There are three judges in most cases, and

two may be always trusted to keep the third straight. The suggestion is certainly good that the National Rose Society's Committee should be asked to codify some rules on the subject. Lord's lays down laws for cricket; croquet and lawn tennis have both their national club rules; how much more should that which is rapidly becoming one of the fine arts? Only let those most competent consult together. As Sidney Smith said to the London Corporation when doubting about putting down the first wood pavement, though far be it from me to apply it in his irreverent spirit, "Gentlemen, you have only to put your heads together and the thing is done."—A. C.

IBERISES.

MR. HARDING's remarks on page 453 and the note appended thereto are opportune, as undoubtedly much confusion exists regarding the nomenclature of these attractive spring-flowering plants. Iberises are yearly increasing in popularity, and

Fig. 88.—*Iberis Tenoreana*.

certainly few plants have a more cheering effect on rocks and in borders in spring and early summer. Their bold yet chaste masses of snowy whiteness are extremely conspicuous, and when the flowers have faded and the plants are neatly trimmed they are yet even attractive by their fresh cushions of green.

There can be little doubt but that the plant alluded to by Mr. Harding is *I. coriacea*, a synonyme of *coriæfolia*; but the synonyme ought certainly to be accepted as the name of this very fine variety, and much confusion would be avoided by two names so similar as *corifolia* and *coriæfolia* being attached to two such dissimilar plants. The name of *coriacea* is with the more appropriate of the two, for the foliage of the plant to which it is applied is decidedly coriaceous, and its flowers are less flimsy than those of most others of the family. The foliage of the plant certainly bears a resemblance to that of some of the *Correas*, but it is not particularly striking, and no harm would be done, but, on the contrary, mistakes would be avoided, by accepting *coriacea* as the distinguishing name for the fine *Iberis* that Mr. Harding doubtless alludes to.

A few years ago a well-known correspondent of the Journal sent me plants named *I. corifolia*. These were greatly admired,

and some visitors on purchasing as they thought the same variety very naturally had plants of the species figured in your last issue sent to them. I afterwards ascertained that my stock was misnamed. Had the name of *coriacea* been generally adopted no such mistake could have arisen.

Mr. Harding is, I think, quite right that *I. saxatilis* and *I. corifolia* are synonymous; but *I. coriacea* is much finer than the species grown under either of those names. It has very large round flowers and handsome flower heads, resembling somewhat those of Tenore's *Iberis*, *I. Tenoreana*. The last-named is a very fine sort, especially for pot culture. Its foliage is very distinct, on account of the lower leaves being smooth and entire, those of the upper portion of the stem being toothed or crenated. The plant is well adapted for rock-work, and, as suggested, it is well worthy of being cultivated in pots. The flowers continue for a long time in beauty, and are very attractive in the greenhouse in spring. For cultivation in borders *I. coriacea* is, I think, the finest of all the *Iberises*.—A. N. G.

A SELECTION OF THE BEST HARDY FRUITS.

LIKE all gardeners who have undergone a thorough training to their profession, when an under gardener I had opportunities of gaining knowledge from many clever masters in large and small places, and in widely different localities, both in north and south. Amongst our evening amusements in the "bothy" particular attention was given to noting down all the work that had been done in each department during the day; when everything was started into growth how long it took the produce to mature, which varieties of fruits were the best bearers, the kinds which hardly ever bore, and those which seldom missed producing a crop. At that time all this kind of information seemed scarcely worth the paper on which it was scribbled, but now I often find it handy as a reference; and as many are now wishing to know which varieties of fruit trees they should plant to insure the greatest amount of success, I have thought that the following selections from my old calendars of sorts that rarely failed to produce a crop under varied conditions might be found to suit their requirements. At the same time I may state the lists are not "old-fashioned," because many of the sorts therein named have ripened very heavy crops this season when fruit crops were a failure generally.

APPLES.—Dessert.—Margaret, the earliest of all Apples; Kerry Pippin; Cox's Orange Pippin, exceedingly good, the very best of all the Pippins; Golden Winter Pearmain, nearly as good, suitable for both dessert and kitchen; Pitmaston Nonpareil, Golden Pippin, Golden Harvey, and Winter Peach. **Kitchen.**—At the Apple election Keswick Codlin headed my list, and I must give it the same preference here. It has only one fault—it will not keep late, but for a sure cropper there is none to equal it, and it is ready for use at a time when few Apples are ripe. Lord Suffield, very large; Hawthornden, very certain; Cox's Pomona, Stirling Castle, Blenheim Orange, Bess Pool, Northern Greening, Norfolk Beefin, and Scarlet Nonpareil. All these will do as standards.

PEARS.—Williams's Bon Chrétien, Beurré d'Amanlis, Autumn Bergamot, Beurré Diel, Louise Bonne of Jersey, Seckle, Passe Colmar, Glou Morçeau, Winter Nelis, and Easter Beurré. Excepting in very cold exposed localities all these succeed as standards.

PLUMS.—Dessert.—Green Gage, Coe's Golden Drop, Jefferson's, Kirke's, Late Orleans, Reine Claude de Bavay. **Kitchen.** What Keswick Codlin is amongst Apples the Victoria is amongst Plums, it bears prodigiously either on a wall or as a bush; Early Orleans, Goliath, Washington, White Magnum Bonum, and Winesour. It is advantageous to place the most of these against a wall. The Damson so excellent for preserving may be grown as a bush in either kitchen garden, pleasure grounds, or orchard. I find this variety requires root-pruning oftener than any other to keep it in good bearing condition.

PEACHES.—Early York, Hale's Early, Noblesse, Royal George, Barrington, Late Admirable, and Walburton Admirable. All these must be grown against a south wall. During some seasons Peaches do not ripen well in the open air. Many err in planting sorts which are late in ripening, whereas by planting early kinds they have a much better chance of ripening their fruit before the bad weather sets in in autumn. The two last-named Peaches are very late.

NECTARINES.—Lord Napier, the earliest and excellent; Elruge, very fine; Violette Hâtive, just about as good; Pine

Apple, Victoria, and Pitmaston Orange. These must all have the support of a south wall.

APRICOTS.—Moorpark and Oullin's Early. These are the most uncertain of all fruit trees in cropping, and I must confess that they are the only varieties in this selection not strictly what they are represented to be—namely, annual bearers. Where the two named fail others will not succeed.

CHEERRIES.—Knight's Early Black, Black Eagle, Late Duke, May Duke, and Morello. Unlike any of the other fruits named these will all succeed admirably against a north wall.

FIGS.—Brunswick, Brown Turkey, Brown Ischia, Bourjasotte Grise. Figs are not so often grown in the open air against walls as they should be. It is very rarely that those named fail, and the heavy crops of fruit they ripen in the autumn are always appreciated. The finest Figs I ever saw were grown on an open wall in a garden in East Lothian.

MEDLARS.—Broad-leaved Dutch, Small-fruited. As these are so much inclined to spread and are not unornamental they are more suited to pleasure grounds or fields than the kitchen garden.

NUTS.—Cosford, Kentish Cob, and Pearson's Prolific may be planted with the Medlars.

GOOSEBERRIES.—Red.—Champion, Ironmonger, Crown Bob, Champagne, Lord Derby, Rifleman, and Warrington. **Yellow.**—Broom Girl, Pilot, Yellow Ball, and Yellow Sulphur. **Green.**—Green Gage, Green Overall, Jolly Angler, and Pitmaston. **White.**—Champagne, Queen Anne, and Whitesmith.

CURRENTS.—Red.—La Fertile, Knight's Large Red, Cherry, Ruby Castle, and Red Dutch. **White.**—Transparent White and White Dutch. **Black.**—Lee's Prolific and Ogden's Black.

RASPBERRIES.—Carter's Prolific, Fastolf, Filbasket, Yellow Globe, and White Antwerp.

STRAWBERRIES.—President, Keens' Seedling, Dr. Hogg, an improvement on British Queen; Elton Pine, late; Lucas, Sir Charles Napier, and Vicomtesse Hericart de Thury.

Just a word to purchasers of fruit trees. Always buy the very healthiest and best-grown examples that can be procured. Stunted weakly-grown trees are very liable to canker, and even if they escape that disease they will not by the time they are fairly into bearing produce half so much fruit as they would have done had they been healthy trees to begin with.—A KITCHEN GARDENER.

EARLY-FLOWERING CHRYSANTHEMUMS.

I HAVE for some years been trying to get a collection of early-flowering Chrysanthemums. I have fairly succeeded, and beg to give your readers a description of the best.

1. *Precocité.*—A beautiful jonquil yellow, 2 inches across. This is in my opinion one of the best both as to form, colour, and for continuous blooming. In flower from the end of August to end of November.

2. *Frederic Pelé.*—Bronze red. Very like the last variety in form, growth, and size of flower. Bloomed from August to end of November.

3. *Nanum.*—Creamy blush. Flowers 2½ inches across. Bloomed in August. Very pretty and desirable.

4. *Durham.*—Pretty primrose. Flowers of good size. Blooms from August to end of October. Last year a plant of this variety had five hundred blooms.

5. *Illustration.*—Colour light pink, changes to almost white. Blooms from August to December.

6. *Adrastus.*—Colour a pleasing crimson. Bloomed in October. This will bloom much earlier under more favourable circumstances. The plant was raised from a late cutting.

7. *Aigle d'Or.*—Pretty yellow, of a large size. Bloomed in October. A very good variety.

8, 9, 10. *Jardin des Plantes.*—Yellow, pink and white, and white. All exactly the same in form and growth, dwarf in habit, profuse in flowers. In bloom from August to the end of October. The yellow variety also known by the name of Golden Madame Damage.

11. *Madame Bachoux.*—White, shaded light purple. Blooms in August. Flowers of good size.

12. *Madame Pecoul.*—There are two varieties of this, light and dark rose. Blooms in August. Very desirable.

13. *Sour Melanie.*—French white. Flowers large. This should bloom in September; with me it was much later this year. It is an exceedingly beautiful variety.

14. *Madame Alphons.*—French white. Very like the preceding variety.

15. *Lucinda.*—Very light pink, in the way of Illustration.

16. *Golden Button*.—Small flower of a rich candy yellow; centre tipped red. Very floriferous. Flowers from September to December. Hardy and desirable.

17. *Delphine Caboché*.—Small flowers of a light reddish mauve colour. Blooms from August to December.

18. *Little Bob*.—Small flowers produced in great numbers, of a dark crimson colour. Very dwarf.

19. *Cassy*.—Small flowers of a pink and white colour. Bloomed in October. Habit good.

20. *Chromatella*.—Orange, tipped red. Bloomed in October. Small flowers.

21. *Ann Mitchell*.—Bloomed in October. Flowers small, of a reddish brown colour. Habit good.

22. *Mrs. Atkinson*.—White, shaded pink. Bloomed in October.

23. *La Vogue*.—Small yellow flowers; centre orange. Bloomed November 10th.

24. *Esther Emans*.—Bloomed in November, of a dark pink colour.

25. *Salamon*.—Bloomed November 7th. Dark rosy carmine. Very pretty indeed.

26. *Argentine*.—Small pure white flowers. This should bloom in September.

27. *Jane Elizabeth*.—Flowers of the button size, of a pale sulphur colour. This should bloom in September.

28. *Lizzie Holmes*.—Yellow. Should bloom in September.

29. *General Canrobert*.—Button shape; colour pure yellow. Bloomed October 25th.

30. *Mrs. Hutt*.—Reddish brown; erect habit. Bloomed November 5th.

The above thirty may all be called early-blooming varieties for the garden borders. The latest of them will bloom, in a good season, not later than the beginning of October. Most of them have flowers of a good size, and are handsome, showy, and of compact habit. They are, too, of easy culture, and they cannot fail to make our borders very gay and attractive during the months of September and October, and, if the weather should be favourable, to the end of November.

I hope to still further increase and improve my collection. I shall be pleased to exchange cuttings with anyone or to know where other varieties are to be purchased.—F. FREEMAN, Middleton Vicarage, Leeds.

AN AMATEUR'S GARDEN AND GREENHOUSE.

I HAVE much pleasure in contributing to the Journal a few notes on my garden and greenhouse experience. Before, however, relating my successes and failures (as a beginner I of course had some of the latter, and gladly accepted them because they taught me how to do things better in future) I ought, perhaps, to state that my garden is not a large one, yet it is of such a size as to keep me fully employed in all my spare time, of which friends tell me I have plenty; but then I rise very early in the morning, which is a great thing. For gardening, like other work, there is no time so valuable and enjoyable as the early morn.

I have no gardener living on my premises. I employ one to do some of the very rough outdoor work and to keep the lawns mowed; but I like to do without him as much as possible, for the reason that apparently very few of the hired men of this locality are competent gardeners. With the exception named I may say that I do all my own work both in and out of doors. Nearly all persons are fond of flowers, but there are some among them who do not care to do any work in order to produce them—they like to have them made like many other things, and look at them without any trouble to themselves. To my mind, in acting thus the real pleasure of having flowers in our gardens and conservatories is lost, and, speaking for myself, I certainly prefer to rear them, watch them, and attend to them, and so have all the pleasures and delight appertaining to floriculture. In this delightful pursuit I regret to say I have not had a very long experience.

Until about two years back I was living in town, and there much gardening cannot be done; still I had a friend in the country who would send me annually a large hamper of bedding plants, and with these I made my "town garden" look cheerful. When I had left town for my present residence I gladly accepted another hamper of plants from my friend for the first summer, but I felt that, having now a good garden and pure air, that was not, as our brethren across the Atlantic term it, the "O. K." thing to do. The plants so sent me were not now sufficient for me; my love for flowers was increasing,

and I must have more of them. Meantime in the spring I had amused myself by making a couple of garden frames in which to raise seedling plants. Although late I sowed some *Pyrethrum*, *Ten-week Stock*, *Indian Pink*, *Phlox Drummondii*, *Balsam*, and others: these with the contents of the hamper afforded me in due season a good display of flowers; but my chief flowers during the summer and autumn were and always will be *Roses*, the queen of flowers. Of these I have nearly a hundred standards and sundry climbers against walls and fences. The standards are planted on either side of the paths, thus forming avenues; they are of a great variety, and when in the months of June and July all are in full bloom they are a very pleasing sight indeed.

The soil here is not a good one for *Roses*, being of a very light character; still with a good mulching of old stable manure in the autumn and an occasional watering with liquid manure when fresh growth commences in the spring and throughout the summer, with careful pruning and the heads frequently played upon with clear water through the garden hose to keep off green fly, I have not only had some excellent blooms, but a profusion of them. Taking them all round they gave me great satisfaction. The following are a few which, perhaps, did the best—viz., *Jules Margottin*, *Duc de Cazes*, *Comtesse de Chabillant*, *Duke of Edinburgh*, *John Hopper*, *Exposition de Brie*, *Alfred Colomb*, *Gloire de Dijon*, *Général Jacqueminot*, *Comtesse d'Oxford*, *Victor Verdier*, *Madame Charles Wood*, *Madame Jules Margottin*, *Baronne de Rothschild*, &c.

These notes comprise my doings, shortly given, for the first year of my gardening; it is purely that of an amateur, and though from the nature of the plants I possessed this year no great skill was necessary for their well-being, they, notwithstanding, required considerable attention in order to make the best of them. The great stumbling-block to my hobby for flowers, and indeed gardening generally, was that I had no place in which to preserve old plants and to propagate for next year's display. This was a great trouble to me. My small garden frames which I had made were all very well to raise a few plants from seeds, but that did not cover my ambition. I must have a greenhouse somehow or other. I had taken my dwelling-house only for a few years, time was fleeing fast, and I did not care to go to the expense of erecting a greenhouse wholly myself, for the reason that in a portable house there is not that facility for heating as in a permanent fixture, therefore I placed myself in communication with my landlady's representative, and after several months' delay we came to terms, which I need not here particularise. This brings me to late in October; meantime there were great doubts as to the success of my negotiation, and I felt somewhat reluctant to make any serious preparation for stocking a house. However, I struck some ten to twelve dozen zonal *Pelargoniums*, in the manner so often laid down in these pages, in anticipation of a house being ultimately erected. It was in due course completed, but I think I had better defer my doings therein for publication in your Journal on some later occasion.—L. HAKEMAN.

GLADIOLI.

I WAS interested in your correspondent's notes about *Gladioli* on page 451, because he is in the same position as I was myself at one time. He seems to believe that there is disease inherent in the *Gladioli*. I freely admit that up to the present year I also laboured under the impression that the mysterious dying-away of the *Gladioli* was attributable to disease; but having last spring improved my system of culture by thoroughly preparing a bed of soil and by what I saw at the Messrs. Kelway's nurseries last September, where there was not the slightest symptom of disease amongst the hundreds of thousands of corms which they grow spread over six acres of land, and the perfect immunity from any losses in my own case when I gave them the soil that suited them, quite satisfies me that there is no real disease. The mysterious losses so common in them arise, I believe, solely from an unsuitable soil or position or an insufficiency of water. For several years I grew the *Gladioli* in the common soil of the garden here and in beds with a portion of the soil removed and good soil added to supply its place; but I met with indifferent success. At last I determined to make one more effort, and I planted them in a well-drained warm border with 2 feet of good loamy rich soil, and the result was all that I could desire. In this spot I planted over three hundred corms last spring, and I

never lost a corm from any cause whatever, and until the end of November the foliage kept in a fresh healthy condition.—J. C. CLARKE, *Gardener, Cothelstone, Taunton.*

A FEW MORE REMARKS ABOUT ROSES.

ALTHOUGH only an amateur I have for years taken great interest in the cultivation of this lovely flower, and mostly work my own plants. I reside in the North Riding of Yorkshire on the verge of the Hambleton Hills, and cultivate the Rose for the pure love of the flower. I have been therefore much struck with the remarks of some of your correspondents relative to individual varieties of this charming flower. Doubtless much is to be gained from the opinions of those who study and cultivate for the intrinsic worth of the plant itself, and the experience of growers situated in different parts of our fickle climate with regard to certain Roses which do or not do well in different districts and situations ought to be estimated as it deserves.

In your Journal of the 29th of November the Rev. W. F. Radclyffe gives his advice as to what Roses he would recommend the public to buy. After giving an excellent list, selected from a former correspondent, he goes on to recommend some Roses as an addition, and among the rest mentions Edward Morren. After long experience in this part of the country I cannot agree with his recommendation of this Rose; although it grows well, it obstinately refuses to open with me, and I have never seen a satisfactory bloom of it in this part of the country. I have therefore discarded it from my collection. I am also much surprised to find that two other favourite Roses here—viz., *Maréchal Niel* and *Marie Baumann*, are classed, the former as one of the "not generally recommendable for the public," and the latter as one of the "generally bad growers."

Were I asked to recommend a Rose as a wall Rose in this part of the country my recommendation would be, *Plant Maréchal Niel*, worked on the Dog Rose, against a south wall. My opinion is that the wild Briar is the stock *par excellence* for *Maréchal Niel*. So vigorous is this grand Rose on this stock here that it grows like a Willow and speedily covers a large wall, and in due course beautifies it with its attractive and numerous blooms. I have been the means of its extended distribution in this neighbourhood, and have not found one to regret having planted it. With regard to *Marie Baumann*, the other unfortunate in your correspondent's list, it is somewhat singular that Mr. Witherspoon, hailing from a quarter farther north than myself, should in the same number of the Journal corroborate what Mr. Radclyffe says as to the bad-growing qualities of this Rose. On the Briar stock this is the best grower and the best bloomer of any Rose I possess, and I have numerous varieties. At the present moment I have a standard of it in an open and exposed situation which is a mass of half-expanded blooms, and it is one of the most satisfactory Roses I possess.

I cordially agree with the advice of Mr. Radclyffe to go and see Roses in a nursery or large collection and you will be able to judge for yourself. Although your correspondent says that the election of Roses, as given from year to year in the pages of the Journal, would deceive the elect, I wish to remark that I have not often been deceived by it, as I have purchased varieties of Roses entirely through their position in the election, and the result has been that I have seldom been disappointed.—GEORGE WHITFIELD, *Thirsk.*

SPRING GARDENING.

THE following paper, abridged from the *Darlington and Richmond Herald*, was read in the Darlington Gardeners' Institute on November 29th by Mr. Atkinson, from Messrs. Fisher, Holmes, & Co.:—

I have been requested to say a few words to-night upon spring gardening. I divide my subject into four classes—first, shrubs; second, annuals; third, herbaceous plants; and lastly, bulbs. I first mention some varieties of shrubs I think suitable, and of which a stock can be procured at any respectable nurseryman's. Amongst the tree varieties of Ivy, *Silver Queen* is most effective; Gold-blotched and *Regneriana* are very fine. There are two very pretty scarlet-berried plants—viz., *Skimmia oblata* and *japonica*. *Eunonymus japonica variegata* and *radicans variegata* are useful plants, and also Gold and *Silver Queen* Hollies. The *Cupressus* tribe affords good varieties, such as *glaucia* and *minima viridis*. The best golden variety

is undisputably *Lawsonia lutea*, as it retains its beautiful golden hue throughout the winter months, the absence of that enduring quality being but too common amongst the golden Conifers. We would also select from the *Junipers chinensis aurea*, *hispanica*, and *excelsa striata*. *Retinosporas* are from their graceful and compact habit of growth very useful for spring gardens, and I would choose from them *plumosa aurea* (a very beautiful plant), *aequalis*, and *ericoides*. We would also recommend *Thuopsis dolabrata*, *laevigata*, and *Standishi*. Amongst Yews, *elegantissima*, *pyramidalis variegata*, and the Golden Irish. In green varieties, *espacioides* and *japonica*. Box, *minima*, *argentea nova*, *chinensis*, and the *Handsworth*, a broad-leaved variety, distinct and fine. The *Berberis*, a graceful type of shrubs, give us *Hookeri*, *japonica*, and *Fortunei*. Yuccas are very effective in the centre of shrubs, and *plicata*, *recurva*, and *stricta* are hardy, cheap, and remain a long time at a manageable size. Many other plants of a kindred nature might be added, but I think the varieties already enumerated are sufficient for most gardens, and, combined with the classes of plants I am about to mention, give a warmth and appearance to the spring garden it would be difficult to attain without them.

I now come to the hardy annuals, a class within the reach of the humblest cultivator, and suitable for the smallest garden. The following, which are of easy cultivation, will be found effective, especially when judiciously arranged as to colour and height:—*Silene pendula compacta*, pink and also white; *Myosotis sylvatica*, *sylvatica alba*, *azorica* and *palustris*, the last being the most valued in the south of England. *Limnanthes Douglasii*, yellow; *Saponaria calabrica*, white and also pink; and for edging *Nemophila insignis*, beautiful blue. The *Nemophila* forms a charming edging to the other annuals. In addition to the annuals I have already named I would recommend a few biennials, such as the Brompton Stocks and the Belvoir Castle red and dwarf yellow Wallflowers.

I will now deal with the third division—viz., herbaceous plants, such as *Ajuga reptans*, *Arabis lurida variegata* and *albida*, *Aubrietia græca* and *variegata*, *Iberis gibraltaria*, *Primulas* in both single and double varieties. *Polyanthuses*, *Saxifrages*, and *Daisies* are useful and pretty; among the latter *Victoria*, white, dwarf red, large-striped, and *ancutifolia* are good—the last especially for edging. The *Dactylis glomerata variegata* is a most useful Grass. I now draw your attention to those most useful spring bedders the *Violas* and *Pansies*. The Great Eastern and Golden Bedder *Pansies* have proved themselves best for that purpose. In *Violas*, *Mulberry Queen*, *The Tory*, *Admiration*, and *Sensation* are conspicuous for their beauty and free blooming among a long list of others.

Our last division is that most esteemed and brilliant tribe—the bulb, which comprises the most beautiful flowers that adorn the spring parterre, the showy Tulip, the stately Hyacinth and *Narcissus*, and the *Crocus* being most used. There are also the several varieties of *Scillas*, *Anemones*, *Jonquils*, *Snowdrops*, and *Ranunculuses*.

I will now describe a bed that I saw last spring at an establishment where spring gardening is much fostered, as it affords an useful hint on arrangement. It was a circle 20 feet wide, and the centre plant was a splendid specimen of *Retinospora plumosa* 2 feet high. The first circle which surrounded it was composed of *Cupressus minima glauca*. Between each plant was a double scarlet Van Thol Tulip. Next came dark blue Hyacinths, followed by a circle of scarlet ones. Then came *Silver Queen* Ivy, with a groundwork of single Van Thol Tulips. Between this line and the centre the bed was covered thickly with *Myosotis palustris* in beautiful bloom. Next outside came *Charles Dickens* Hyacinth, porcelain, followed by *Sultan's Blush*, surrounded by a row of white Hyacinths. The next circle was *Eunonymus radicans variegata*, alternately with single Van Thol Tulips, carpeted with *Golden Thyme*. Following were separate circles of *Mauve Queen* Viola, *Ajuga reptans*, *Golden Bedder* Pansy, and *Saponaria calabrica*. The outer line was composed of the *Aucuba*-leaved Daisy, the whole forming as charming a combination of spring gardening as I have ever had the pleasure of seeing.

DECEMBER FLOWERS AT VEITCH'S.

HAVING recently had a day at my disposal for visiting a London nursery I elected to have a look round Veitch's. My object was to ascertain what plants were "in" at this dull period of the year when the *Chrysanthemums* are fading, when *Camellias*, *Azaleas*, and forced shrubs are yet flowerless,

and when bulbs, except Roman Hyacinths and a few early Tulips, have not awakened from their summer's sleep.

December is proverbially a dull month. The weather is often dull, trade is often dull, and gardens are generally dull during the few weeks preceding the great national festival of Christmas. The country I know is dull at that time, and I did not find the town particularly lively. The streets were greasy and the atmosphere was murky; even that dull structure, Temple Bar, looked duller than usual, for I found the preparations for its demolition, or at least removal, had just commenced. I found too, of course, a crowd watching the proceedings—a real London crowd that is notorious for good humour; but the crowd even was not true to its character, for not a joke did I hear, not a smile did I see, as I elbowed my way through the solemn or sullen multitude. I arrived at "the office;" here at any rate it was not dull, for publishing happened to be in progress, and boy-loads, and man-loads, and truck-loads, and van-loads of Journals were being dispatched. "Holloa!" was the greeting. "What! you here! A dull time for visiting London." "But I'm off to Veitch's; it isn't dull there, is it?" "No; at least they came out well at Kensington the other day. But go and see for yourself and let us know what's going on." I went. The greeting was again pleasant, yet—shall I write it?—dull, for the first words of the courteous official were half apologetic. "Come in, but I'm afraid we have not much to show you; it's a dull time, you know." I began to think the dullness was chronic, and that December had not its name for nought. But dullness after all is a relative term. What Mr. Taylor, who lives amidst flowers, may consider dull others may deem cheerful, and certainly I found sufficient to cheer at Veitch's.

The collection of Orchids was first inspected. Here, summer or winter, there is always something to attract notice. I saw the grand *Cattleya exoniensis*, of which I had read such glowing accounts, and found it more beautiful than I anticipated; brilliancy and chasteness are combined in this remarkable variety. Its flowers, however, are now fading. A few other *Cattleyas* are also flowering, including a fine variety of *C. Mossiae*, but none of them are equal to *C. exoniensis*. Wherever such plants are grown there this *Cattleya* should be. Very conspicuous are the Butterfly Orchids, *Phalaenopsis grandiflora* and *amabilis*. Their large pure white flowers are exceedingly beautiful, and are among the choicest of the choice for Christmas decorations. *P. Schilleriana* is showing strongly; even without the flowers the plant is attractive by its handsome marbled leaves, with them it is superb. In contrast with the larger forms of this genus the smaller-flowered *P. Parishii* is noticeable. Where sufficient heat can be afforded these plants are highly worthy of a good share of it. No Orchids are more free, for even tiny plants in thumb pots throw up their spikes readily. That remarkable Orchid *Angraecum sesquipedale* is in fine condition, and is showing several flowers. It is one of the plants of which the firm cannot get enough of. In remarkable contrast is the still more rare *A. citrinum*. No wreath can be imagined more perfect than that formed of the two rows of small creamy white pink-suffused flowers arranged with the greatest exactitude on the slightly arching stem. Those who have this plant will treasure it, those who have it not may be excused for coveting it. Another white-flowered Orchid now in beauty is *Cymbidium eburneum*. The massive texture of this flower and its great purity places it very high in the scale of beauty; indeed, Mr. Denning places it in the highest position, for I once heard that well-known cultivator remark that if he was compelled to name what he considered to be the most beautiful flower in creation it would be *Cymbidium eburneum*. The Australian *Dendrobium Johannis* is flowering, but it is more curious than beautiful, yet its dark twisted sepals render it distinct. Really and unquestionably beautiful, however, is *Laelia autumnalis*. This is a most valuable December flower. It is represented by several varieties, ranging in colour from pale lilac to purplish violet. It grows and flowers freely, and must be ranked as one of the finest of its season. Somewhat of the same pleasing colour, and in growth and flowers resembling a miniature *Gladiolus*, is *Bletia hyacinthina*, half a dozen plants of which in a 7 or 8-inch pot produce an attractive effect. *Vanda tricolor* commands notice by the health of the plant, the size of its spikes, and the beauty of its flowers; it is very fine. Attractive also are the elegant racemes of *Saccolabium giganteum*. A few *Oncidiums* contribute their deeper and brighter colours to the general display. *O. varicosum* is fading, but the more persistent *O. Barkeri* continues fresh and cheerful. It has a

fine spike and numerous flowers, the predominating colour being pale primrose. In contrast with it is the deep cinnamon-brown *O. crispum* and the still brighter and finer *O. Forbesi*, the yellow fringe of which renders it very gay; and erect and stately is the darker-flowered *O. purpuratum*. The good old Orchid *Zygopetalum Mackayi* is in excellent condition, having luxuriant spikes of its finely marked flowers. It is a valuable "back-row" plant for this period of the year. *Epidendrum ciliarum* is noticeable, not however so much on account of its beauty as for its remarkable lip, which is fringed like delicate-textured lace.

In the "cool houses" a few plants assert their winter decorative value. The well known and deservedly popular *Odontoglossum Alexandrae* is showing freely, and the plants are remarkably fresh and sturdy. So popular is this *Odontoglossum* that it has to be grown by the thousand to meet the great demand. *O. Rossi majus* is also flowering; it is dwarf and attractive. More stately is *O. Pescatorei*; and finer still, indeed exceedingly beautiful, is *O. cirrhosum*. A more valuable and important Orchid than this has not been introduced for many years past. It possesses every quality to render it popular. It grows and flowers freely in a moderate temperature, producing fine branching spikes and flowers of remarkable beauty. It has been imported, too, in such large numbers that it can be distributed at a cheap rate, and now that it is within the reach of so many who possess houses in which it can be grown satisfactorily I would suggest that, if possible, it be figured, for although it has been distributed so largely and is well known to Orchid growers generally there are yet many lovers of December flowers who are as yet unacquainted with this, one of the very best of them. Another Orchid—more lowly than those named, yet much more bright, perhaps even the brightest of all—is also flowering, *Sophranitis grandiflora*. This dwarf epiphyte is growing on cork, but only a few of the plants are in beauty; their rich scarlet flowers are extremely telling. *Masdevallias* are cool Orchids of great value and easy culture. *M. tovarensis*, the distinct and charming Columbian species, is highly attractive. The habit of the plant is dwarf and compact, and the flowers are of the purest white and continue fresh for a long time. Equally distinct is the bright golden yellow *M. Davisii*, which is about expanding. Other fine sorts are *M. Lindeni*, magenta purple; *M. Harryana*, rich violet crimson; and *M. Veitchiana*, orange scarlet shot with purple. These dwarf and beautiful Orchids cannot be too "highly commended."

A notice of this class of plants would be incomplete without allusion being made to the *Calanthes*. No "December flowers" are more useful than these. Although destitute of foliage during the flowering period they are yet valuable for associating with other plants—convenient too, for they can be placed amongst "foliage" plants without crowding. They are extremely cheerful; indeed one cannot be dull even in "dull December" where well-grown *Calanthes* are. They are very serviceable too for cutting, the spikes having an excellent effect in vases, while the individual flowers are the "very things" for button holes. The new variety recently noticed in your Journal, *C. Sedeni*, is now fading. It represents a lucky cross by Mr. Seden, who has been fortunate in transferring the rich blotch of *C. vestita* to the centre of *M. Veitchii*. It is a remarkable example of the potency of artificial fertilisation. Besides the two useful *Calanthes* named—*vestita* and *Veitchii*, white with a chocolate blotch, and rosy purple respectively—*C. vestita lutea*, white with a yellow blotch, and *C. vestita alba*, pure spotless white, are flowering freely. The last-named variety is particularly chaste; the flowers are of excellent form and very attractive. These valuable and easily-grown plants are yearly increasing in public favour, and it is necessary to increase them largely to provide an adequate supply.

Yet another family of Orchidaceous plants merit special attention as "December flowers"—namely, *Cypripediums*. These plants flower freely at other periods, but they never show to greater advantage than now. The skill of the hybridiser has been richly rewarded by a succession of new and distinct varieties, some of which are not yet in commerce. Amongst those flowering now are *C. Harrisianum*, a fine dark flower; *C. Arthurianum*, brighter and much spotted; *C. marmorophyllum*, distinct by a suffusion of mauve, rosy stripes, and fine marbled foliage; *C. Schlimii*, a lovely light variety; *C. pardinum*, heavily spotted sepals; *C. venustum*, a similar yet darker flower; and the valuable and luxuriant *C. Sedeni*. The last named is an established favourite. Another variety of sterling merit is *C. insigne Maulei*. The typical species is

a good old plant, but is far surpassed in beauty by the improved variety—improved by its larger flower and by the clear white corona on its upper sepal, which renders it so attractive. Few plants are more easily cultivated than these; given efficient

drainage, light rough open soil, water as required, and moderate heat, and they will grow freely and flower with certainty at a time when their flowers are welcome; they, moreover, last longer when cut and placed in water than most other flowers—

FIG. 89.—*ODONOGLOSSUM CIRRHOSUM*.

lasting, indeed, fully three weeks. Thus *Cypripediums* are plants of considerable importance for winter decoration. It is not only the Orchids in flower that merit the approval of visitors; the great number of plants of all sizes and their health and cleanliness have a large share in sustaining the interest, especially of those who inspect the collection for the first time.

Among other plants now flowering in the nursery *Cyclamens*, as may be expected, are largely represented. A houseful of these plants produces quite a cheerful effect, and the perfume is delightful. Another large house is almost entirely occupied with "tree" or perpetual-flowering [Carnations, and so admired

are the flowers that they are cut almost as fast as they expand. Many of the varieties flower freely in 4 or 5-inch pots, and such plants are very valuable for various decorative purposes. The sorts chiefly in demand are Miss Joliffe, flesh colour; La Belle, white; Czar, mottled scarlet; Rose Perfection, bright rose; and Mons. Baumann, bright glowing scarlet. There is also a stock of the good old *Souvenir de Malmaison*, which produces such ponderous blooms. A white *Dianthus*—a variety of the Mule Pink, *D. hybridus*—is flowering in small pots, and is very pretty. In the Carnation house a *Veronica* of great merit is flowering freely—*V. Hendersonii*. It is a short-jointed rather small-leaved sort, yet not so small as Blue Gem, and has dark

blue flowers which are sweet-scented. It is an excellent December flower of the easiest culture. *Bouvardias* are indispensable for December, especially for affording bouquet flowers, and are largely grown. The most popular varieties are *Vreelandii*, *Hogarth*, *Longiflora*, *Flammula*, *Reine des Roses*, and a new dwarf bright-coloured sort named *Leeiantha*. *Abutilons* are nearly always in flower, and perhaps none are more useful than the white *Boule de Neige*. The new yellow *Boule d'Or* is distinct and bright, and *Rosæflorum* is a pleasing variety. *Fuchsia Dominiana*, which has almost been forgotten for years, is well to the fore. Since it has been seen how easily it can be grown and how bright and effective it is in December there has been "quite a run" on it. Heaths—especially *Ericas byemalis*, *gracilis*, and *cafra*—are December flowers of recognised merit, and cannot well be dispensed with, as also are

Statice Holfordi and *profusa*, and *Lasiandra macrantha floribunda*. The new rosy scarlet *Poinsettia* has fine heads and bracts. It is quite distinct from the "old sort," and affords an acceptable change. The double variety is not yet in beauty. Such plants as *Euphorbia jacquiniæflora*, *Centropogons*, *Plumbago rosea*, *Eranthemums*, *Amarylliseæ*, double *Primulas*, and *Epiphyllum violaceum* and *tricolor*, contribute to the general display. In one of the stoves the fine *Ipomœa Horsfalliæ* is flowering profusely. Besides the handsome flowers the black glossy flower buds of this plant are effective. Several small plants of *Ixoras* are yielding bright trusses. *I. Williamsii* and *I. Fraserii* are very free, and flower attractively in 4 and 5-inch pots. In the stove also a number of plants of the brilliant *Abelandra Roezli* are showing; also *Gesneras*, which are not much less bright, and are of easy culture. A shelf in a stove

Fig. 90.—*ADIANTUM LÜDDEMANNIANUM*.

will accommodate these plants during their season of growth, and when flowering they are worthy of the most prominent positions. *G. exoniensis*, *G. refulgens*, and *G. cinnabarina* combine handsome foliage with beautiful flowers. Perhaps the last named sort is as useful as any for general decorative purposes.

Of greater intrinsic value than many of the plants named for producing high-class flowers during the winter—indeed, nearly at all seasons of the year, are the *jasminiflora-javanica* type of *Rhododendrons*. One of the parents of the type, *R. jasminiflorum*, is yielding beautiful white flowers now, while other colours, also better foliage and habit of growth, are provided by the newer varieties. A beautiful trio are the following:—*Taylori*, bright rose, white tube; *Duchess of Edinburgh*, scarlet; and *Princess Alexandra*, white faintly suffused with rose. A smaller and new plant which must not be overlooked for winter decoration is *Col. Trevor Clarke's Begonia Moonlight*. It has the dwarf habit and rich dark foliage of *Pearcei*, with a profusion of round flowers neither

white nor yellow, but "moonlight" colour. It is very free and attractive. There is a remnant of *Lapagerias*—a few blooms of the lovely *L. alba*, which is quite one of the most charming flowers in creation. Of Pitcher-plants there is a considerable display. The flowers enumerated are not grouped together to produce an imposing effect, but are scattered over a great number of structures according to the requirements of the several plants.

Ornamental-foliaged plants—*Crotons*, *Dracænas*, *Palms*, *Aralias*, *Tillandsias*, *Marantas*, *Alocasias*, and *Palms*—are very numerous, and are as beautiful in their way as flowers, and cannot be dispensed with for winter decoration. Ferns also are ever charming. The crested Maidenhair (fig. 90), *Adiantum Lüddemannianum*, is both curious and elegant, and its dwarf habit of growth renders it suitable as a fringe plant in prominent positions.

Camellias are swelling their buds; they are mentioned, however, for the purpose of directing attention to the examples of handsome specimen plants in tubs, which illustrate in a

striking manner the importance of severe pruning and high culture. The plants have at some time or other apparently been cut down much after the manner of pruning Pelargoniums, and they are now well-furnished specimens, glossy and vigorous. A few—only a few—Azaleas are flowering; but many houses are required to accommodate the stock of these plants, so popular are they for spring embellishment.

And now a word—not on flowers nor ornamental-foliage plants, but on trees. Christmas is drawing near, and Christmas trees are an institution. Not a word shall be said against the familiar and homely Spruce Fir, for it will aid in making glad homes innumerable during the festive season; but for a Christmas tree more rare and more choice, what can equal a fresh, handsome, young specimen of *Arancaria excelsa*? Of this beautiful tree it is necessary to provide largely at Chelsea, and propagation of it is constantly going on. Not alone in the conservatory is it handsome in the form of a large specimen, but in a small state it is excellent for vases, and it is not more suitable for a Christmas tree and for decorating rooms in winter than it is ornamental as a "subtropical" plunged on lawns in summer. On inspecting a large collection many varieties are apparent; some light in appearance, some massive, but all pleasing. One of the more sturdy and dense in the leaflets is named after a noted continental nurseryman—Napoleon Baumann. A. Cunninghami is more slender in habit than *excelsa*, and A. Ruiei is much more robust, and, to use a nursery phrase, it is full of "character."

I have now told you, Messrs. Editors, what is going on at Veitch's, and have satisfied myself that it is not dull there.—A COUNTRYMAN.

NOTES FROM CORNISH GARDENS.

ROSEMUNDY HOUSE, ST. AGNES.

CORNWALL abounds with odd nooks and corners of which the world knows little or nothing, lying, as most of them do, away from its beaten tracks and busy haunts—unknown to fame, unnoticed in guide books, and yet so beautiful with beauty of a high degree and peculiar order as well rewards an explorer for his pains in finding them. My readers have already been made acquainted with one such nook in my description of Lamorran. Let me now take them to what is literally a corner—Rosemundy House, the residence of W. Naylor Carne, Esq., near St. Agnes Head, a rocky promontory on the north coast, about as unlikely a situation for a good garden as—well, as was the site of the beautiful grounds at Battersea Park in its original form of a low flat damp piece of waste land.

It was by an early train that we set out from Truro, for that day we had three gardens to visit in the mining districts, but situated at a considerable distance apart, so there was nothing better than taking time by the forelock in order to get through a long day's work satisfactorily. At the little station of Chacewater we found Mr. Carne had come to meet us, and glad enough were we, for without his kindly assurance that better things were in store for us we might have been tempted to turn back from the melancholy aspect of the bare and rugged surface among the tin mines through which our road lay. The mines are soon passed, and we actually revel in our enjoyment of a natural transformation scene so lovely as to be worthy of a special journey to see it alone. A minute ago we were driving through a district apparently blasted and death-stricken without a vestige of vegetation, and now we are in a flower garden brilliant with full rich summer beauty, for the road is fringed on both sides with broad margins of wild Heath that are just one dense mass of blossom running outwards to and clothing the face and top of raised-wall-like banks on either hand—a mingled growth of various kinds, all alike laden with crimson, pink, and purple bells, those on one patch especially being so large in size and brilliant in colour that we were constrained to pause for a closer inspection. For part of the way belts of trees behind the Heath enhanced its beauty, the varied greenery of foliage forming a charming foil to the cushion-like clusters of gay flowers, and then the country opened out into a vast level expanse—bare of trees, but with a pleasant air of brightness and animation imparted by the glistening waters of the Atlantic, visible on either hand, betokening our nearness to our destination, of which we have still stronger evidence in the sight of St. Agnes Beacon, a conical hill having an altitude of upwards of 600 feet, and not far from the foot of which lays Rosemundy in a valley running from north to south, and therefore not parallel to the coast, which here runs in a westerly direction to St. Agnes Head.

Snug and cosy is Rosemundy, nestling down among the trees, out of sight and sound of the sea; but it was not so naturally—the trees had been planted, banks had been thrown up and planted too with hardy shrubs to screen both house and garden from the south-western gales that frequently sweep inland from the vast ocean which lies so near, and the flourishing condition of the garden afforded ample proof how thoroughly these simple means of shelter had been applied and how well they answered.

"Mine is not a fine garden, but it contains a few choice plants," said Mr. Carne, as he led the way into it. A few plants! save the mark. It is a regular storehouse of floral gems, all growing in such rude health and crowded together in such profusion as to be absolutely bewildering. To catalogue them all would have been a work of two or three days, and as my visit hardly extended to as many hours I could only note some of the more conspicuous and such as appeared likely to answer in other gardens.

We first entered a small sunken panel lawn adjoining the house, snugly enclosed by walls and banks on the other sides. Many rare climbing plants clothed the walls—the glossy Chilean *Escallonia illinita* with white flowers; a handsome evergreen *Elæagnus*, which Mr. Carne called *E. japonica*; *Garrya elliptica* femina, also remarkable for handsome foliage; *Elæagnus pungens* variegata, very curious; and to these I may here add *Solanum jasminoides*, very lovely and perfectly hardy; and *Magnolia Lenne*, with very handsome foliage. Of other notable plants in beds and borders here there were grand clumps of New Zealand Flax; large tufts of *Plumbago Larpentæ*, gay with pretty pale blue flowers, an old but valuable perennial not often met with; *Hydrangea paniculata grandiflora*, a curious and lovely form with flowers opening white but quickly becoming suffused and blotched with deep pink. This must take a leading position among dwarf flowering shrubs as well as in the perennial border from the great beauty of its flower clusters. *Acanthus spinosus*, bold and effective, having deeply-serrated spinous leaves and tall flower spikes bristling with spines. It is easily raised from seed, which is not expensive. Then there was the Double White Bramble (*Rubus flore albo-pleno*) in great beauty, and also the Double Pink variety *R. roseo-pleno*, both fine trailing plants growing into large bushes, so ornamental that it is matter for regret they are not more common. *Cornus mascula* variegata, one of our best variegated shrubs, was also good here, and of *Pittosporum undulatum* there was a wonderful example 7 feet high and nearly as much in diameter, the black-stemmed branches and handsome glossy foliage being even more striking than the fine form of the shrub, which was in excellent health, as was a still more extraordinary example of the Blue Fiddle Wood—*Citharexylum cyanocarpum*, usually regarded as a denizen of the stove, but growing freely enough here in the open garden, the Myrtle-like foliage curiously alternating with spines. *Colletia cruciata* was also growing freely, and was apparently quite established. I was not surprised at this, having heard of its answering tolerably well in some other gardens.

The shrub most used to clothe the banks of this and other enclosures was the Japanese Privet—*Ligustrum japonicum*, a handsome shrub much in favour in the public gardens of London, and which Mr. Carne has found to grow vigorously in exposed situations, apparently revelling in the sweeping winds that prove fatal to so many other shrubs. Certainly nothing could be more satisfactory than the deep green glossy hue of its broad handsome foliage, which forms such an admirable foil to its bold white flower spikes.

Among other enclosures we found whole banks of *Cyclamen* and curious lawns composed of a mingled growth of grass and Primroses of all sorts of colours. Several magnificent specimens of *Gunnera scabra*, with leaves upwards of 4 feet in diameter and numerous spikes of yellow flowers and seeds. Hard by there was a fernery, the Ferns being planted among some rocks in large numbers, comprising, I should think, all known, and perhaps many unknown, varieties—certainly unknown to me. Among them I was glad to see a conspicuous position given to *Lastrea recurva*, not very common, but one of our best hardy Ferns, always beautiful, but especially so in winter, when its pretty bright green fronds stand out so conspicuous while most other varieties of its species have lost all beauty. A charming little Alpine plant, *Mentha corsica*, was clothing many of the rocks with dense cushions of tiny green foliage. The Cornish Moneywort, *Sibthorpia europæa*, also found a suitable home among the rocks, and I must not forget

to mention that the true Cornish variety of Maidenhair Fern was well represented.

The garden abounds in snug little nooks and cosy enclosures, every one of them turned to account to test the merit and hardiness of plants, shrubs, and even trees collected from distant sources, widespread as the world itself. Near the large fernery we pause to admire a curious and very beautiful species of Bramble from Australia—*Rubus australis*, with hardly any leaves, the green flexible branches being thickly set with little white spines. Further on we find an example of the "Omboo," the only tree found on the South American Pampas. Then we come upon an irregular heap of rocks turned to account for a collection of Alpine plants, a Prostrate Willow brought from the High Alps being pointed out as worthy of notice for its pretty spreading growth. Near the rocks some Fig trees heavily laden with fruit were worthy of special notice, the fine crop being attributed to careful manipulation of the growth the previous season, every strong shoot having had its tip nipped off when it was a few inches long, inducing it to put forth three or four other shoots, Mr. Carne having thus in his culture followed the lead of Nature; for as the Fig bears its fruit near the tips of the shoots made a year before, so "the more shoots the more fruit" was the guiding principle in his treatment. Of other rare shrubs I may add the Japanese *Desmodium penduliflorum* laden with lovely bright purple flowers, quite hardy here, as indeed it is also in the neighbourhood of London; the Silvery-variegated Bramble was also bright-looking and attractive; *Arundo conspicua*, too, was in full beauty. I note this from a desire to see this fine Grass more frequently; it throws up its elegant plumes quite two months before the Pampas Grass, and is highly ornamental.

Many other choice plants and shrubs must be left unnoticed, for the garden is literally crammed with botanical rarities, affording convincing evidence of a devotion to and success in collecting and cultivating them that is rarely met with. Mr. Carne is emphatically a pioneer, so thoroughly in earnest as to propagate and offer plants of his choicest novelties to his friends and neighbours, for his is no selfish love. "Add to my pleasure by sharing it with me," says he; and thus wisely and well does he strive to foster and render popular a science which he loves and understands so well.

The glass houses contained plants of a similarly uncommon character. A collection of such succulents as *Opuntias*, *Stapelias*, *Cacti*, and others remarkable for the quaint guise of their growth and the beauty of their flowers were there in considerable numbers. The most tender sorts of exotic Ferns, too, have a house specially devoted to them. All were thriving; not a sickly plant did I see. And this is perhaps the most extraordinary thing about this garden where everything is extraordinary—that although the whole of the plants were new, rare, or uncommon, yet the healthy vigorous appearance of every one of them showed that each received the treatment best suited to its requirements, and my only regret was that my hurried visit prevented me from learning more of skill so well applied and work so thoroughly well done.—EDWARD LUCKHURST.

PREPARING FOR CHRISTMAS.

SCENE Covent Garden Market; date December 18th; time 5 A.M. Weather delightful, as clear and mild as a May morning. Produce enormous, visitors numerous, vendors noisy, purchasers active. No time and no place could probably have afforded such evidence of the magnitude of preparations for the coming festival, at least so far as garden products are concerned. The most striking feature of the Market were the mountains of Holly, richly berried and brilliant in the gaslight.

Those who have not seen this year's Holly harvest as garnered at Covent Garden can form no conception of its enormous extent. For some days past small donkey carts, large horse vans, and railway trucks have been conveying their loads of Holly to the metropolis. The streets contiguous to the Market were almost blocked with Holly, which the "costers" scrambled for and distributed over the thousands of homes of the city and environs. But there was enough for all and to spare, for the supply was as bountiful as it was brilliant. Mistletoe was much less plentiful, and was quickly "collared." Christmas Trees—young Spruce Firs—were represented by many thousands. Laurel and other evergreens were not in great request; the trade in these was spoiled by the extraordinary plethora of Holly.

FLOWERS.—Dear at all times to Londoners are flowers, but at Christmas they are indispensable. The immense resources of the market growers and their cultural skill were admirably displayed. Primulas sturdy in growth, rich in foliage, and remarkable for the high "strain" of the flowers, were there in "loads." Lilies of the Valley, Dutch Hyacinths, and early Tulips were in charming profusion; *Ericas*, *hyemalis* being excellently grown; *Veronicas*, *Cyclamens*, *Poinsettias*, *Epiphyllums*, a few *Azaleas*, *Echeveria retusa*, and *Solanums* were the staple floral products offered, and quickly purchased, at this great mart in preparation for the coming festival. Bouquets were composed chiefly of white Roses, pink *Geraniums*, *Camellias*, *Eucharis*, *Azaleas*, *Bouvardias*, and Ferns; feathery Grasses in divers colours and Everlastings formed in tasteful devices were attractively displayed; and, as if these were not sufficient, artificial flowers and sprays were almost as "loud" in their extravagant colours as their vendors were in shouting their charms.

FRUIT.—How deficient is the supply of British-grown fruit for the Christmas requirements of the head quarters of the nation was evidenced by the tons of Apples sent from America and the Continent. Pears are large in size but limited, and Grapes somewhat disappointing. The finest were *Gros Colmans* and *Alicantes*; the largest bunches were of *Gros Guillaume* at Mr. Webber's, who also sustains his fame as an importer of Pine Apples. Bananas, Shaddocks, and Tomatoes were represented, while Nuts and Oranges were apparently sufficient to supply a nation, much more a city.

VEGETABLES.—Immense and superior was the supply. Roots of all kinds, from the thousands of sacks of Potatoes, piled-uploads of Turnips, Carrots, and Parsnips, to the hampers of Onions and Beet and bundles of Horseradish were provided for the million of a quality equal to that at the disposal of the aristocracy. Savoy, Coleworts, and Kale composed the bulk of green vegetables; but Brussels Sprouts were plentiful and excellent, and Broccoli was also well represented. Rhubarb and Seakale, all kinds of salads, Cucumbers, Mushrooms, and Truffles were provided to meet the demands of a populace preparing for a feast. Herbs also, especially Parsley and Sage, were provided on the same scale of prodigality. Yet enormous as was the display of garden products it was only an instalment, and at least two more similar markets will be held before the preparations are completed.

The immense provision cannot be contemplated without recognising how great is the industry of horticulture; how necessary it is in ministering to the wants and comforts of life; how important it is as being the sole means of livelihood of thousands who are engaged in it; and how great, natural, and intimate is the alliance between city and country—between homes and gardens, lords and labourers! Let us hope this dependance on each other may be more and more recognised, and the interchange of good wishes incidental to Christmas will not be peculiar to that period alone. Covent Garden tells how much of benefit and pleasure gardens afford, and how worthy they are of the best efforts of all who are engaged in their cultivation.—A CITY MAN.

COMPARATIVE MERITS OF PEAS.

DURING the past season I had the opportunity of testing about sixteen varieties of Peas, and possibly a few remarks on their respective merits may be of service to some who limit their seed bill, and consequently the introduction of novelties also.

The past season was, and in this district often is, very unfavourable to the growth of Peas. Cold easterly winds were very prevalent till late in May, and from that time till the middle of September we had not a good soaking rain. Ours is rich soil on a clayey loam subsoil, and autumn sowings are generally failures. None of the Peas were sown on shallow soil. Preference was given to double-dug ground, and from these sowings we obtained our best and most prolonged pickings. The second earlies and very late sorts were sown on the ridges between the Celery trenches. They thus obtained two spits of soil, as the spaces between the trenches were previously dug. The remainder were sown in trenches prepared as for Celery. This plan is very well where there is plenty of water at hand, but such was not the case with us. The soil in the trench shrank from the sides, and a poor crop was the result. In consequence of continued wet weather we were unable to sow the earlies till the end of February, and even then had to cut out the drills with the spade and replace

with drier soil. I will now briefly describe the varieties grown:—

Dickson's First-and-Best was first by a few days, and is a good early, equalling any of the Ringleader type; William I. is, however, decidedly the best yet tried here for early work. This variety is strongly recommended for late sowing by a well-known vegetable grower, and I was informed by a gentleman who had tasted this Pea in October that it equalled in flavour any Pea he had tasted through the season. Next spring I intend sowing this variety on turves under glass to be subsequently planted in the open border, and seed saved from the produce will be sown for late work. Early Matty, an old variety sent me by a friend who had grown it for thirty years, closely followed William I. for earliness. It is remarkably vigorous and productive and of fair flavour.

Dickson's Favourite was grown this season as a second early, but will in future be discarded in favour of Dr. Maclean. This variety has become very popular, especially as an exhibition variety. It is a very useful Pea, being dwarf (2 feet 6 inches), and very prolific, the pod long and well filled, but with us not quite so well flavoured as expected. Hair's Dwarf Mammoth is not unlike Dr. Maclean, but not so good. It is very useful as a second early, and also for late work, but will be discarded in favour of the Doctor. Huntingdonian is an excellent second early, height 4 feet, a good cropper, and the flavour unsurpassed. It is a type of the Champion of England, but it is in every way superior to and will be grown in preference to it. G. F. Wilson for flavour and size of Peas was unsurpassed, but both this and Laxton's Fillbasket could not stand the dry weather, coming into bearing prematurely. I shall give them another trial. Veitch's Perfection still ranks as a first-class Pea either for main or late crop. Giant Emerald Marrow (Sutton) is a very distinct and fine Pea. It is very vigorous and productive, but as the Duchess of Edinburgh (Sutton) comes into bearing about the same time, and is a better quality Pea, it will be grown in preference to it. The last-mentioned Pea is decidedly a fine Pea, and may be described as an improved and early Ne Plus Ultra. Williams' Emperor of the Marrows is another excellent Pea, and both this and Culverwell's Prolific Marrow ought to be grown for late work. The former is the earliest, but for quality and appearance I give the preference to the latter. Ne Plus Ultra completes the list, and is the best for very late work. All five of the last-mentioned Peas are tall; some of them, notably Williams' Emperor, reached 7 feet.

Many acres of Peas are annually grown for market in this neighbourhood. The crop sometimes proves very remunerative, and, what is still better, the picking gives employment to numbers of women and children. The varieties grown for early picking are principally Sangster's No. 1 and Caractacus, the latter being considered the best. Laxton's Supreme, Veitch's Perfection, Yorkshire Hero, and Blue Scimitar are all largely grown, and some of the more enterprising growers are raising a stock of Dr. Maclean and other new varieties.—W. IGGULDEN, Orsett Hall, Essex.

PORTRAITS OF PLANTS AND FLOWERS.

LILUM NEILGHERRENSE. *Nat. ord.*, Liliacæ. *Linn.*, Hexandria Monogynia.—“This is the only Lily of the mountains of Southern India. It inhabits the Neilgherries and Pulnies at an elevation of about 8000 feet above sea level. It is closely allied to *L. Walliechianum* of the Himalayas, *L. philippinense* of the Philippine Islands, and *L. longiflorum*, japonicum, and Brownii of China and Japan. It was introduced by Mr. Thomas Lobb in 1862, but failed to become established, and has lately been imported again in considerable quantity by Messrs. Veitch and others.”—(*Bot. Mag.*, t. 6332.)

ALLOPLECTUS PELTATUS.—“Introduced by Messrs. Veitch from Costa Rica, where it was collected by the late Mr. Endres, and flowers from July to the present month (November) in our stoves. This is another of those Gesneriads remarkable in having one leaf of each pair permanently rudimentary.”—(*Ibid.*, t. 6333.)

STENOSPERMATUM WALLISII. *Nat. ord.*, Aroidæ. *Linn.*, Icosandria Monogynia.—“One of Mr. Wallis's important discoveries in tropical America, introduced to cultivation by Messrs. Veitch; exhibited two years ago in flower, and described, together with an excellent woodcut and detailed analysis, by Dr. Masters in the *Gardeners' Chronicle* about the same time. The pure ivory-white nodding spathes freely developed amongst the clustered dark shining green leaves render this plant one of the most valuable of our stove Aroids for ornamental cul-

ture. It belongs to a small genus consisting altogether of but four or five species peculiar to Columbia, Peru, and northern Brazil.”—(*Ibid.* t., 6334.)

GLADIOLUS ECKLONI. *Nat. ord.*, Iridacæ. *Linn.*, Triandria Monogynia.—“This is a most distinct and beautiful species of *Gladiolus*, marked by its comparatively dwarf habit, ensiform leaves, and, as compared with the best-known Cape species, small flowers, with innumerable minute spots of bright red-purple on a pale groundwork. It is widely spread in South Africa, extending from Uitenhage northward through Kaffraria to Natal, and inland to Basutaland and the Transvaal. As it ascends to a height of 3000 or 4000 feet on the Katberg we may fairly expect it to be as hardy in England as any of the Cape species. For the specimen figured we are indebted to Mr. Elwes, who flowered it at Cirencester in October. He procured it from Mr. Wilson Saunders, who had it from Mr. Thomas Cooper from the Drakensberg. We confidently expect it will prove a popular favourite.”—(*Ibid.*, t. 6335.)

ERANTHEMUM LAXIFLORUM. *Nat. ord.*, Acanthacæ. *Linn.*, Diandria Monogynia.—“For this very desirable addition to our autumn-flowering Acanthads we are indebted to Messrs. Veitch, for whom it was introduced from the New Hebrides. Specimens are also in the Kew Herbarium from the Fiji Islands, collected by the late Dr. Seemann, where, he states, that it is frequently cultivated by the European settlers as an ornamental plant. It is a shrub or half-shrub, attaining from 2 to 4 feet in height, wholly glabrous.”—(*Ibid.*, t. 6336.)

NOTES AND GLEANINGS.

THE ANNUAL DINNER OF THE DURHAM, NORTHUMBERLAND, AND NEWCASTLE HORTICULTURAL AND BOTANICAL SOCIETY was held at the Alexandra Hotel, Newcastle, on the 17th inst. The chair was occupied by the Mayor, Mr. Thomas Robinson, in the absence of Col. Joicey, the new elected President for the forthcoming year. This Society had for some years only a feeble existence, but it has suddenly increased to prodigious dimensions, chiefly through the indomitable exertions of the Hon. Secs., Messrs. Taylor and French: The members now number about four thousand, while the income has been for the last year nearly £2200; during preceding years it scarcely ever exceeded £300. The Society has made window gardening a chief feature, and has assisted the flower-missions in the district. It was a successful meeting of a flourishing Society.

—We are glad to observe from an advertisement in another column that the Council of the Royal Horticultural Society have decided to appoint an ASSISTANT SECRETARY, and we trust they will be successful in securing the services of a gentleman possessing the necessary technical qualifications together with the business aptitude requisite for the efficient performance of the important duties pertaining to the office.

—How valuable ORCHIDS are for winter decoration, writes a correspondent “L.” the fine display in Mr. B. S. Williams' nursery at Holloway affords sufficient evidence. Amongst those now in beauty are *Calanthes Veitchii*, *vestita luteo-oculata*, and *rubro-oculata*. *Cypripediums* comprise *Dayanum*, *venustum spectabilis*, *Crossianum*, *Harrisianum*, and *insigne*. *Odontoglossums* are represented by *Inseleyi*, *Alexandra*, *rubescens*, *Andersonianum*, *luteo-purpureum*, *Rossii*, and *Rossii majus*; *Oncidium*s by *ornithorhynchum*, *tigrinum*, and *papilio*; *Vandas* by *tricolor flava*, *tricolor superba*, and *tricolor insignis*; *Lælias* by *autumnalis* and *præstans*; and *Dendrobiums* by *nobile* and *bigibbum*. *Cymbidium Mastersi*, *Zygopetalon Mackayi*, *Saccolabium giganteum*, *Rodriguezia secunda*, *Maxillaria picta grandiflora*, and *Masdevallias ignea* and *polysticha* also contribute to the display. *Griffinia hyacinthina* is also flowering, and is extremely attractive. Amongst the ornamental-foliaged plants *Croton falcatum* is highly effective by its fine leaves, which are nearly 2 feet in length and brilliantly coloured.

—A CHESHIRE correspondent states that *AGERATUMS* are still uninjured by frost in his garden, and he has potted a number of plants, which will yield flowers for cutting for the next two months. Scarcely any plants “lift” better than *Ageratums*, and few flowers are more valuable during the winter months for vase decoration.

—THE HON. and REV. J. T. BOSCAWEN states that the INDIAN STRAWBERRY (*Fragaria indica*) has become naturalised in Cornwall. It is a distinct species, with pretty yellow flowers, and was introduced to this country in 1805.

—“W. P. J., Mortlake,” writes approvingly of Williams'

MATCHLESS RED CELERY. He describes it as being not only one of the most hardy sorts grown, but very solid, crisp, and of unsurpassable quality. It resists both wet and frost, he says, better than any sort he has cultivated.

— A "GROOM AND GARDENER," writing to us on CHRISTMAS FLOWERS, states that he neither regrets the decay of the beautiful white *Anemone Honorine Jobert* nor envies his neighbour at the Hall the possession of the aristocratic *Eucharis* so long as he has half a dozen large clumps of the Christmas Rose, similar to those recently alluded to by Mr. Robson, and as many large hand-lights to place over them. With a supply of these beautiful hardy winter flowers, a few spikes of the scarlet *Schizostylus*, protected in the same way, a few sprays of the bright yellow *Jasmine* from a south wall, a dozen expanding buds of the old Monthly China Rose gathered from a bush in a sheltered corner, a little Holly, sprays of Conifer, and a few fronds of Ferns, he can furnish a vase for Christmas decoration in such a manner that, as he says, "no one need be ashamed of." The vase, he suggests, should be filled with very moist and clean silver sand, in which the flowers, &c., can be arranged more artistically than in water, and they continue fresh equally long as if placed in water.

— ANOTHER case of SEED-DYEING has been the subject of magisterial inquiry, and with results that will commend themselves not only to purchasers but to all honest vendors of seeds; indeed, it is gratifying to observe that it is by the action of seed merchants that the law is being enforced against dishonest practices in connection with the important trade in which they are engaged. Mr. W. G. Harley, Guy's Granaries, Mermaid Street, Borough, was on the 15th inst. fined £5 and the cost of the summons for selling one cwt. of Alsike Clover seed, which Mr. Bernard Dyer, F.C.S., had analysed and found to contain 8 to 10 per cent. of foreign seeds dyed with indigo. He produced specimens of dyed seeds which he had separated, including Trefoil, Timothy Ribbed Grass, Thistles, &c. Notwithstanding the defence submitted, Mr. Partridge, the Magistrate, took a common-sense view of the matter, and ruled that "a purchaser who asked for Alsike was entitled to that particular species of Clover and no other"—hence the conviction, which deals a death blow to "dyers" and "doctors" of seeds.

— It is not necessary to visit gardens and shrubberies in the country to obtain evidence of the great crop of HOLLY BERRIES that is produced this year. The streets of London have recently borne ample testimony on the subject, for piled-up loads of Holly glistening with myriads of scarlet bead-like fruits have daily arrived to deck the shops and homes of the great metropolis during Christmastide. The contrast between this year and last in the "commerce" of Holly is very striking. Last year the sprays were nearly fruitless, this year they are much more thickly clustered with the coveted berries than we ever remember to have seen them during many years' observation.

— We are informed that the spring Show of the READING HORTICULTURAL SOCIETY will be held on May 23rd, and the summer Show on August 22nd.

— THE RAINFALL for last November at the gardens, Nannau Park, upwards of 700 feet above the sea level, was 11.56 inches. Rain fell on twenty-six days; 1.77 inch fell on the 11th alone!

— We recently recorded that Mr. Cannell was awarded a first-class certificate by the Floral Committee of the Royal Horticultural Society for White Vesuvius Zonal Pelargonium. We have seen flowers of another sport which Mr. Cannell has obtained from Vesuvius, which gives a new colour for bedding purposes. As near as its colour can be described it is a very high-toned salmon, or, in other words, salmon suffused with scarlet, with a white eye; it is quite different to other salmon zonals. In habit of growth and freeness of bloom it is identical with the original, and is a very promising variety.

— We are informed that eight prizes were gained at the Birmingham Show for Potatoes grown with AMIES' MANURE. Fine samples of produce were exhibited as having been grown by the manure on soil which those who have seen the land describe as naturally poor and "worn-out." It produced average crops the first year, and ever since the produce has been good.

— We recently incidentally alluded to *EUCARIS AMAZONICA* as grown by Mr. Denning in Lord Lonsborough's garden at Norbiton. We never saw such a display of this charming

flower in December as is there produced; and the mode of culture is of the simplest. The plants are planted-out in a well-heated pit; they have grown like Rhubarb, and are now yielding such a crop of flowers as we have never seen equalled in number nor surpassed in quality. Mr. Denning has assuredly made a great "hit" in thus easily providing a supply of this esteemed flower in such profusion for Christmastide decoration.

— THE AMERICAN DODDER recently noticed as having attached itself to a plant of *Forsythia suspensa* at Glasnevin is not, according to a closer subsequent examination of it by Dr. Moore, *Cuscuta cephalanthi*, but *C. reflexa*.

— FEW plants are more worthy of culture for conservatory decoration during the winter months than *DAPHNE INDICA RUBRA*. The glossy green foliage and rich rosy flowers are alike attractive; but the chief claim of this plant to notice is its powerful and delightful perfume. The flowers are also remarkable for their lasting quality, continuing fresh and enjoyable for three months. Small plants in 4 and 5-inch pots are particularly valuable for various purposes of decorations in rooms and greenhouses during the months of December, January, and February. This variety is not only the best in colour, but is the most free in growth of the somewhat slow-growing section of the genus to which it belongs.

— A SELECTION of flowers of seedling *POLYANTHUSES* from Mr. Cauldwell, florist, Wantage, suggests how useful these flowers are for winter decoration. Their vigour and freshness also affords evidence of the mildness of the weather in Berkshire. Many of the flowers are good, some excellent, and all gay. A crimson self Pansy in the same box is a promising variety; the colour is distinct and rich, and the petals are of great substance.

— We have received from Mr. Henry Hooper, Vine Nursery, Widcomb Hill, Bath, a number of *PANSIES* of remarkable beauty. For size, form, substance, and well-defined colours combined we regard them as amongst the most meritorious blooms that have come under our notice. The colours range from pure white with violet-purple blotch to rich crimson maroon. The yellow grounds and selfs are also very rich. The fancy varieties are particularly showy; the blooms are well formed and the lacings well defined. It is clear that Pansies are not exclusively northern flowers, but are hardy flowers for all gardens; and such varieties as those now before us cannot fail to please when they are well cultivated. We have not received a brighter "Christmas-box" than the one composed of these Bath Pansies.

— For bright appearance and excellent quality combined "A VILLA GARDENER" writes that no variety of Cabbage equals Sutton's GOLDEN BALL SAVOY. It is as bright in colour, he says, as Golden Feather, and is particularly tender when cooked and delicate in flavour.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

KITCHEN GARDEN.

THERE is not much difference in the details of our work from what has been previously given. The last two seasons have shown the importance of an efficient system of drainage, especially on heavy wet soils, and when other work cannot be proceeded with this may be done, and it ought to be done well. A main drain should be laid at the lowest part of the grounds, and the smaller drains, about 16 or 20 feet apart, should have their outfall into this. The outfall of the main drain should always be kept clear, and not be choked with any accumulation for some distance from its mouth. In heavy wet soils, which are most retentive of moisture, there will be a continuous flow of clear water all the winter in such seasons as this. When a new garden is formed on such soils the first step towards laying it out is to begin at the drainage. It may cost a trifle more to do it thoroughly, but this extra outlay is more than compensated by the satisfaction of knowing that the work will not have to be done again after the walks are formed and the trees just established in the borders.

It has been our lot to work in gardens composed of the heaviest soil, such as when it was dug it clung to the spade in wet weather like marl. We have also had to do with soil of the lightest description, and where the gravel cropped up to within a few inches of the surface. We certainly prefer the heavy soil, as it can be much improved by judicious trenching and manuring. If the ground has not been worked to a greater depth than 10 or 12 inches it is not wise to go down more than 3 inches more the first time of trenching it, and this can be done

By digging it two spits deep, placing two layers of half-decayed stable manure in the trench, one layer at the bottom, and the other after the first spit has been placed over it. If this is done now, so that the weather can act upon the surface for two or three months, the ground may be brought into excellent order for cropping; it will merely be necessary to fork over the surface to a depth of 3 inches. Half-decayed leaves are useful for keeping the soil porous. Road scrapings are also useful for this purpose. Of course the very opposite treatment is pursued with regard to light soil; and heavy loam, if it can be obtained readily, may be laid on the surface to the depth of 6 inches or more, and be dug in. We advise seeds to be sown rather thickly on heavy soil, as on such soil they are likely to be injured. The plants will not grow so freely at first, but they will do so much better afterwards, especially if the weather is dry.

Young Cabbage plants are blown about by the high gales we have had, so much so that the plants work round in a basin formed by the swaying of the stem. This is easily set right by drawing the soil round the stem with a hoe. Slugs are also troublesome, but we kill them by dusting the plants with quicklime at night. Lettuces suffer most from their attacks.

CUCUMBER HOUSE.

The plants are making very little growth, but they produce as many fruits as we require. We still hold to Tender-and-True to produce fruit both in summer and winter. We lost our old stock, but the seedlings obtained from seed sent by Messrs. Veitch vary but little from the original stock. Mr. C. Turner of Slough sent a single seed of a variety that promises well for winter work. We have propagated it by cuttings, and it has borne fruit earlier than any other sort planted with it. This may be owing to the difference in size of the plants when they were put out; still it is very free in bearing. It resembles Telegraph in the size and shape of the fruit, but it is darker in the skin than that sort, and has black spines. Every year there are numbers of Cucumbers reputed to be new exhibited at South Kensington. A large proportion of them are merely variations of Telegraph; but this good old sort has stood the test of many years' trial, and if by careful selection it can be improved or kept up to its own standard we shall not be in want of a good winter Cucumber. Small fruit about 9 inches or a foot long are the most useful for winter, as two may be produced instead of one. Thrips are very troublesome when the house has to be kept close and the leaves dry. We do not know any better way to destroy this pest than by fumigating with tobacco smoke. This must be done with great caution, as the young tender leaves are very apt to suffer from the effects of it when it is applied too strong. Red spider, another terrible enemy, can only be removed by syringing.

VINERIES.

The temperature in the early house started last week has not been increased beyond 45° during cold nights. Our object is gradually to increase the heat until in two weeks more it is about 50°, and not going higher than 55° until the buds are started. When they have pushed a few inches the temperature may be run up a few degrees higher. We do not syringe at all after the buds are fairly started. Before this the stems are merely kept moist by gently dewing them with a very fine rose. If the water is applied with force it washes off the mixture, which is not desirable. We keep up the moisture by fermenting material, and that best adapted for this purpose is composed of equal parts of leaves and fresh stable manure. A bed of this will throw off a large quantity of steam, and its rankness will have gone by the time any buds are started. The steam from fresh manure even in a small quantity is dangerous to the tender young leaves. We cannot obtain leaves, but we use manure in small quantities, adding about two barrowloads at a time to keep up the heat when it shows symptoms of declining. We also place some fermenting material on the outside borders, and cover it with shutters to keep the wet and frost from it. For early forcing the shutters are indispensable, not only to retain the heat in the fermenting material, but to keep the autumn rains from saturating the soil before forcing is commenced.

We have cut all the Grapes in one of the late houses, and placed the stems removed with the bunches in bottles of water in the fruit room. They are not cut from the house containing Lady Downe's, but from a Muscat house where Muscat of Alexandria, Gros Guillaume, and Mrs. Pince are cultivated.

PLANT STOVE.

In one of our houses there is a bed filled with tan. Some of the plants are merely placed on the surface of the bed and others are plunged in the tan. This is according to the character of the plants. If they are healthy and the pots well filled with roots we do not plunge, but a little bottom heat excites root-action in plants that are newly potted or that do not start freely. In a few weeks we shall sift the spent tan, retaining the rough portion and wheeling out the fine, mixing the rough with some new material. The heat from tan is the most lasting; it does not heat very strongly, so that it does not wear out so rapidly as the more violent heat of stable manure. Oak leaves,

if they can be obtained in quantity sufficient for the purpose, are excellent for bottom heat.

Clerodendron Balfourii is certainly one of the most useful plants we have either for training up to cover the rafters or back stage of the stove or as large or small specimen plants. It can be recommended, too, for another reason: While some other climbing plants are very subject to the attacks of red spider, thrips, or mealy bug—the last the most dreaded enemy gardeners have to contend with in the stove—the Clerodendron is never attacked; insect pests cannot live on it. Our summer-flowering plants have now thoroughly completed their growth and we shall remove them into a cool house. Stephanotis floribunda has also made very good growth. The plants in pots will be kept rather dry at the roots; they will have just enough water to prevent their flagging. There is no need to sing the praises of Dipladenias as useful decorative plants. The large showy flowers of D. Brearleyana are esteemed by everyone. D. boliviensis, pure white with yellow throat, is very useful for cutting, and its freedom in producing flowers is not the least point in its favour. Our plants are at present making vigorous growth. We have tried them by allowing them a season of rest all through the winter months, resting them in a temperature of 55° and keeping the soil rather dry, in fact not giving them any water for six weeks at midwinter; but they do not succeed so well with this treatment. They have now a temperature of 65°, and we water them carefully, as Dipladenias do not require very large supplies. They should not receive any water at the roots, especially in winter, until the soil in the pots is drier than most plants would like it. These plants, as well as the Stephanotis, are subject to the attacks of mealy bug, and if this pest is not destroyed now by careful handwashing it is unlikely that the plants will do well in summer. Ixoras should also be carefully examined and all traces of bug be removed. Specimen plants intended to flower in June should now be cut down and be kept in a heat of 65° as a minimum, increasing it to 70° in six weeks from now. It will be difficult to keep up a supply of flowering plants in the stove without Orchids, but we have on previous occasions alluded to the easy manner in which some of the different species may be grown, and the low price at which Calanthes and some others may be purchased permits no excuse to be without them.—J. DOUGLAS.

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

NOTICE OF LEAVING (*A Gardener*).—The most correct mode of proceeding is to give notice of your intention before seeking for another place.

REMOVING ROSE TREES (*O. Z.*).—Legally a tenant has no right to remove the trees he has planted, unless he has the landlord's permission to remove them.

STOVE IN PLANT HOUSE (*E. S.*).—We know of no stove that has no chimney to carry the smoke or gases emitted into the open air which is not injurious to the plants in the house.

BLACK MANURE (*J. Davis*).—Not knowing of what it is composed we cannot give an opinion. Quicklime dissolved in water and applied by a brush will kill the moss on the trunks of trees.

APPLES (*H. S. Fraser*).—Write to Messrs. Webber, Central Avenue, Covent Garden Market, for the information.

EVERGREEN SHRUBS NEWLY PLANTED (*H. B.*).—Manure spread on the surface would not injure them.

GREEN ON WALL (*A. Braid*).—The green on the greenhouse wall is caused by the damp air. Quicklime and water applied with a brush will remove it.

PEACH TREES FOR ORCHARD HOUSE (*W. H. B.*).—We only know one of the three you name—viz., Double Montagne. It may do for the orchard house, but we have not tried it, as there are so many better. Maltese (Malta?) is a good Peach and succeeds in an orchard house.

FORCING RHUBARB (*F. J.*).—Place the Rhubarb roots in the bottom of the barrels with the crowns upwards, adding sufficient soil just to cover the crowns, that is all. Dress your border of herbaceous plants with decayed manure, and let the rains wash it in.

ROOT-PRUNING FRUIT TREES (*Inquisitive*).—Dig a half-circle round the trees at the distance of 3 or 6 feet from the stem, according to the size of trees. The largest trees require the greatest distance to be allowed. Cut all the roots by digging a trench 2 or 3 feet deep, then work towards the tree with a fork and lift the roots up, cutting off all that descend. You must not remove the tree entirely, as it will receive too great a check. Place some fresh loam amongst the roots.

HEATING GREENHOUSE (*D. H. W.*).—As it is not convenient to place the pipes side by side, place one above another. It is of no consequence which way in your case. We cannot recommend the valves of one firm more than

another. Use the wash for the Vines that has been recommended in "Doings of the Last Week."

FORCING IMPORTED LILY OF THE VALLEY (Inquirer).—It is not unusual for imported clumps to remain dormant if placed, immediately after potting, in a high temperature. Pot and plunge them in a bottom heat of 75° and not exceeding 90°, and cover with inverted flower pots, taking care that the soil does not become dry. Every crown will grow, and when the spikes are about 5 or 6 inches high then withdraw the pots from the hotbed and place them in a house with a temperature of 65° by day and 55° at night, in which they will expand the flowers and develop the foliage. In the new year they will succeed admirably in ainery started at that time; but the plants must be brought on gradually with the Vines or they will remain dormant or go "blind," which is obviated by bottom heat or a rising temperature, commencing from a low one. If we understand you aright, however, your crowns potted last year never started into growth; if so the same crowns cannot be relied on for forcing now.

POTTING LILIAM AURATUM AND LANCIFOLIUM (Idem).—The roots at the base of the bulbs must not be removed, but the stem roots above the bulbs, also the stems of last year, should be removed. The soil employed for potting being moist, as it ought, no water should be given until the shoots appear, when it should be given so as to maintain the plants in a healthy growing state, increasing the supply with the growth. Plunge the pots in ashes in a cold pit or frame, though they will do outdoors buried in that material until March or early April, when they must be placed in a light airy position in a greenhouse or other structure of moderate temperature.

DRESSING LAWN WITH QUICKLIME (Idem).—The lime must be slacked before placing it upon the grass, as lumps or heaps of lime unslacked will in slacking be so heated as to destroy the grass it rests on. About eighty bushels will be sufficient for an acre, spreading it evenly over the surface, and after a thorough rain remove any stones, rolling well. It will destroy the worms, also moss, but they will again infest the ground after the lime becomes converted into chalk.

BEGONIAS (Inquirer).—There are hundreds of varieties too nearly alike to enable their being named from single leaves.

EARTHWORM (Country Vicar).—It does not eat the roots of plants. It draws worms into the mouth of its hole in the earth to exclude intruders.

ASPARAGUS NEGLECTED (A Subscriber, Freshfield).—Your best plan will be to prepare a piece of ground by trenching and enriching with manure. This to be done as soon as possible, so that it can be exposed to the action of frost, and early in the spring, when sufficiently dry to work cleanly, fork it well over again so as to bring it into a loose friable condition. Immediately you perceive the Asparagus above ground fork up the roots carefully by undermining them, and plant them again in the new bed. This work must be done with as little exposure as possible to the roots. If they are transferred without being dried during the process of removal, and are planted in drills or trenches sufficiently wide so that the roots can be spread out without being doubled, and an inch or two of light soil, such as decayed leaves or vegetable soil, is worked amongst them, levelling in with the ordinary soil and watering with tepid water, they will grow. They will not grow with certainty if removed when in a dormant state, and you cannot eradicate the weeds you name without digging up the Asparagus.

CINERARIAS NOT EXPANDING (E. S. L.).—As you say the plants are healthy we think the flowers will open as the season advances. Keep the roots active, and the plants in a temperature ranging between 40° and 50°. You have perhaps been trying to force them.

INSIDE VINE BORDERS (Puzzled).—Good crops of Grapes have been and are grown when the Vine roots are wholly in inside borders, and at the same time many failures have occurred, chiefly through imperfect waterings. Inside borders are often kept too dry, not only in summer but in winter.

WHITE CAMELLIA (Villa Garden).—For freedom of growth and flowering we do not think any surpasses the old Double White, Alba plena. Fimbriata is very beautiful, but we think a little more delicate than the other.

RAISING CUCUMBER PLANTS (Amateur).—As you only require three plants we advise you to purchase them, or you might secure the friendly aid of a neighbouring gardener who has heat at his command. The most difficult part of Cucumber culture at this early period of the year is in raising strong plants for planting out. You will require as much heat to raise three plants as three hundred.

CLEANING VINES (W. P. Leeds).—As your Vines were infested with thrips we should simply wash the rods with a strong solution of soft soap or Gishurst compound, dissolving 5 or 6 ozs. in a gallon of water. Let the washing be thorough. You will find an old spoke brush useful for the purpose, and the solution may be used at a temperature of 150° immediately the Vines are pruned.

NAMES OF FRUITS (Young Botanist).—The Apple is Hanwell Souring. The Lycopodium is denticulatum. (G. L.).—Old Colmar.

NAMES OF PLANTS (J. W. L.).—We cannot name from such fragments. (Devonian).—1, Plantain (Plantago major); 2, Hypericum Androsæmum. (Sir Astley).—Adiantum cuneatum and Oncidium flexuosum? (T. G.).—1, Justicia speciosa; 6, Santolina, probably S. Chamæcyparissus; the others are florists' varieties.

POULTRY, BEE, AND PIGEON CHRONICLE.

THE POULTRY CLUB.

MEETINGS having been held at the Crystal Palace and Birmingham, during the time of the late shows, of those interested in the formation of a Poultry Club, with the object of placing the exhibition of poultry on a more honourable basis than it has of late held, the following code of rules has been agreed upon as a starting point:—

1. That the Club be called The Poultry Club.
2. That the objects of the Club be—1, The promotion of the breeding and exhibition of poultry; 2, The suppression of fraud and dishonourable conduct therein; 3, The advancement and protection of the interests of poultry breeders and exhibitors.
3. That the Club consist of Members whose annual subscrip-

tion shall be a guinea, and Associate Members whose annual subscription shall be 5s.; that such subscription be payable in advance.

4. That in case the subscription of any Member or Associate Member shall be in arrear for three calendar months his or her name shall be removed from the books of the Club, unless some satisfactory reason be given for the non-payment.

5. That the officers of the Club be a President, a Vice-President, two Treasurers, and a Secretary.

6. That the Committee consist of the officers of the Club, who shall be *ex-officio* members thereof, and eight other members, who shall manage all the affairs of the Club; that three of their number (one at least of whom shall be an officer) form a quorum.

7. That the officers and committeemen be elected annually on the 1st of January by the whole body of members; that half of their number shall annually retire, but be eligible for re-election.

8. That the voting for the election of officers and committeemen be conducted by means of voting papers, which shall be sent by the Secretary to every member.

9. That Associate Members have like privileges with Members save in the election of officers and committeemen, in which they shall have no vote.

10. That a general meeting of the Club be held annually at the Crystal Palace at 3.30 P.M. on the second day of the Show for the discussion of all matters connected with the Club, and that it be in the power of the Committee to convene extraordinary general meetings.

11. That the Members and Associate Members be elected by the Committee.

12. That candidates for election send their names to the Secretary, and that the Secretary forward a list of candidates for election to all the members of the Committee.

13. That if any Member or Associate Member be proved to the satisfaction of the Committee to have acted dishonourably, he or she shall be forthwith expelled from the Club and forfeit all interest in it.

14. That any Member or Associate Member so expelled have the right of appeal to a general meeting of the Club specially convened for the purpose.

15. That the Committee be empowered, *inter alia*—1, To employ a solicitor for the purpose of advising or otherwise assisting its Members and Associate Members; 2, To prosecute defaulting committees of shows; 3, To prosecute railway companies and others for cruelty or other offences; 4, To assist Members and Associate Members in obtaining the solution of legal questions of interest to breeders and exhibitors of poultry.

16. That a list of Officers, Committee, Members, and Associate Members, as well as a balance sheet and report, be annually printed and sent to every Member and Associate Member, to all exhibitors at the last Birmingham and Crystal Palace Shows, and to any other person applying for the same.

17. That the names of original Members be published in the poultry newspapers, and that the names of additional Members be published from time to time.

18. That none of these rules shall be altered except at the annual general meeting, or at an extraordinary general meeting convened for the purpose. That notice of any intended alteration be sent to the Secretary at least two months before the meeting, who shall give notice to the members of the proposed alteration.

The Committee chosen to start the Club are the Hon. and Rev. F. G. Dutton, Hon. and Rev. A. Baillie Hamilton, Rev. Hans F. Hamilton, Rev. W. Serjeantson, O. E. Cresswell, A. Darby, R. A. Boissier, T. C. Burnell, J. Hinton, R. E. Horsfall, T. E. Manby, E. Pritchard, S. Matthew, C. Sidgwick, and R. B. Wood; and it was resolved that this preliminary Committee should be considered as the Committee till March 1st, 1878, when the Club will elect its future officers and Committee. About 120 fanciers have at present signified their wish to join the Club, and others wishing to do so should send their names at once to Mr. O. E. Cresswell, Early Wood, Bagshot, R.S.O., Surrey.

THE PARIS POULTRY SCHEDULE.

To many of our poultry exhibitors who have for some years now been accustomed to a small schedule and entrance form for exhibiting their poultry, the schedule of the Paris Universal Exhibition of 1878 will probably be confusing. There are fifty-six classes, or "categories" as they are termed, where the cocks have divisions to themselves while the hens have to be in trios, except in the case of Turkeys and Geese. In the schedule the French most properly come first, there being classes for Houdans, Crêves, the Flèche (the La being dropped), Mans and Bresse breeds, with another variety French fowl class. The Cochins follow, where, instead of our "Buff or Cinnamon" we find "Yellow or Chamois." Classes there are, too, for Whites, Blacks, and any other variety of Cochin; Brahmas, Dorkings, Hamburgs, and Game have no subdivisions of varieties. The

"seventeenth category" is for "Russian, Malay, and similar breeds," which is surely rather abstruse. Polands are called Padua and Dutch breeds, of which the White-crested have two classes. There is a class for Breda fowls, which we should have thought should have been grouped with the other French varieties. Two Variety classes with categories for Geese, Turkeys, Ducks, and Guinea Fowls finish the poultry department. The Pigeon classification is peculiar. There are but four classes—one for large breeds used for food and one for smaller ditto, another for Doves, and the fourth for Carriers. Rabbits have five classes, one being for Russians.

The prizes are fairly liberal. An art object of the approximate value of five hundred francs may be awarded to the finest collection belonging to the same owner, and a sum of four thousand francs and silver and bronze medals will be distributed among the attendants to whom the notice of the Jury may be drawn on account of the intelligent care they have given to the prize specimens; so there will be a good opportunity for some of the poultry managers of England to come in for a share of this £170, and in cases of equal merit the Jury will take length of service into consideration. Of the other prizes, in the classes for cocks the prizes are thirty francs, twenty francs, and fifteen francs, and in those for hens they are forty-five, forty, and thirty-five francs; besides these a silver medal will be added to all first prizes and a bronze medal to all other prizes. No exhibitor can receive more than one prize in each class. The entries have to be sent to the Secretary Royal Commission Paris Universal Exhibition, 1878, Canada Buildings, King Street, Westminster, S.W., and being "on Her Britannic Majesty's service" the postage need not be paid.

One fact will seem peculiar to our exhibitors; we allude to the Show being judged by special Juries, the third of which will judge the pigs and poultry. Save Capt. Heaton we personally know of no English judge who would give satisfaction to English exhibitors of both pigs and poultry. There is a clause, however, to say each Jury may perhaps be divided into sections, in which case the poultry may possibly have a small Jury to themselves. The awards will be determined upon by a majority of votes, and in cases of equality the President will have the casting vote; their decision will be taken down in writing and signed by the members. All this must appear very strange to us and would appear to require a great deal of time, but art. 16 tells us that the Jury will have two days in which to perform their duties. Wednesday, June 5th, is set apart for the reception of the animals, and the Show closes on the 17th inst. at 5 P.M.

The time of year is a bad one for a poultry show: old birds will be ragged and untidy while the chickens will hardly be ready, though we have seen early chickens win at the Bath and West of England shows, which are generally held at about that time. We anyhow hope our exhibitors and fanciers will patronise the Show, and do what they can for the foreigners to see that the basses cours of Great Britain have even French fowls equal to their own in size, points, and general characteristics.—W.

CARMARTHEN POULTRY SHOW.

THE great number of other shows which were being held in other counties on the same dates doubtless interfered with this one, where the classes, though extremely well divided, had not such tempting money prizes. Some of the classes were small, such as the Spanish, Light Brahmas, and Gold and Silver-pencilled Hamburgs. There was a class for undubbed *Game*, with £5 5s. worth of prize money offered by the Baroness Burdett-Coutts, but only eight entries were made; and though the winner was a good bird, still a £3 first prize would have brought a larger competition from the greater yards we should have thought. *Malays* were a good class of fifteen pens, and the winners were well chosen. In Black *Hamburgs* the winning pair (D. Lewis) were very bright and good. *Polands* only had five pens, but the winners (Hinton) were very good Silvers, fine in crests and attractively marked. In the class for *Houdans* Mr. S. W. Thomas won second with a pair which were not in the catalogue from some oversight; third going to a good pen of Mr. Scott's. In the other variety French class *Crêves* won all the three prizes. The first *Game Bantams* (Parker) were smart and good-coloured birds, and in the other Bantam class Mr. Phelps with his three entries monopolised the three prizes. In the Any other variety of fowl class the Rev. R. Woodgate was first with a capital pen of Japanese Silks, second going to W. Lewis for Black Minorcas. In the Sale class the Rev. D. Williams was first with a fair Dark Brahma. The local classes were mostly of average merit, but call for no especial remarks. Mr. John Martin awarded the prizes, and gave general satisfaction.

MID-SURREY POULTRY SHOW.

THE second annual Show was held at the Drill Hall, Kingston, on Thursday the 13th inst. and following days. The arrangements were an improvement upon last year, but a want of

practical knowledge is still evident with the management. The avenues were too small, and, the light not being good, it was a very difficult task to inspect the birds in the lower pens, and the inconvenience must have added wonderfully to the work of the Judges.

Old cock and hen, cockerel and pullet, was the general classification of the popular varieties of poultry. Considering the space at the command of the Committee, we think they would have done much better had they been less ambitious, and as the season is now far advanced, made one All ages class for each variety, it would have saved a considerable sum in prize money, and they could have spared a little to have increased the value of the other prizes, which would have improved greatly the quality of the birds, as exhibitors do not care to risk good specimens in the chances of an exhibition for prizes of the value of 20s., 10s., and 5s., unless they are very conveniently situated with regard to the Show, as was the case with a large Pigeon exhibitor, who patronised the Show most extensively, and we noticed in only the first five classes of Pigeons he was fortunate enough to take thirteen prizes out of the fifteen offered. We call attention to this in the hope that if the Show is continued the Committee will see the advantage of condensing their schedule, expunging some of the unpatronised classes, and then, by the slight increase we have suggested in the values of the prizes, the competition will become more general and an improvement of the quality in many classes will be secured.

Dorkings, five classes.—The first, a cockerel, we thought the pick of the lot. The winning pullet was in some respects good, but spoilt by sooty feet. *Cochins*, Partridge.—First good, cock sound in colour, hens well marked. Buff were generally very uneven in colour. In the Any other variety we found two good pens of Whites first and second, and a moderate pen of Black third. *Brahmas*, Dark Cock and Hen.—First, cock rather narrow, hen well marked; second a fair pen; third poor. Light Cock and Hen.—First both good in colour, and the cock had a very neat comb for an old bird. We could not find another even moderate pen in this class. Hooked Birds.—The winning Dark had all that the most extravagant lover of leg feather could desire for breeding purposes, but the merit of the first Light hen we could not discover; she was wonderfully hooked, but very short of leg feather, the third toe being quite uncovered. Cockerels a poor class. First a pretty bird, second deserved his position, third crooked in the toe. Pen 89, a pair of Lights, we much preferred. Pullets.—A very evenly-marked Dark first; second a well-shaped White, nicely marked in the hackle, and with a proper quantity of leg feather. *Game*.—Black Red cocks a fair class. Hens.—First a very stylish bird, short and hard in feather. Duckwing.—Pen 129 we liked in many respects better than the winner, but he looked out of condition and soft. The remaining classes were poor, the Any variety of hen containing only one entry. *Hamburgs*.—Mr. Long exhibited two or three good pens. The first Leghorns were good. *Polands* only one entry. *Malays* a fair class. *Spanish*.—First deserved their position, the cock had a face of good quality and was well shown, hen was deficient in lobe. Pen 170 contained a beautiful hen with a grand face and well-shaped lobe. Pen 171 a cock almost as good as the winner. Both these pens belonged to the same owner, had he matched them differently he would have run very close for the first prize. *Andalusians*, five entries, all good. *Bantams*, Red.—We thought the second pen showed more style than the winner. Any other variety, Ducks were first and second. Ducks were generally good.

Pigeons.—Pouters.—In Pied cocks Mr. Herrieff succeeded in obtaining a second prize with a good Red. This was the only pen shown in opposition to Mr. Baker in the three Pouter classes. Carriers obtained more support. Dragoons were capital classes. Blue cocks first and second, good coloured birds, and nice and distinct in the bar; third had a good Dragon head, but was a little cloudy in the bar. Hens.—First a good bird, second showed a little too much of the Carrier. Dragoons, any other colour.—A very sound-coloured Yellow first. A capital Chequer, a good coloured Red, and several very good birds were to be found here. Hens.—Yellow first and third, the competition being close. Jacobins another good class. Mr. Hardy showed a Red that we thought might have been higher in the prize list. English Owls, nine entries, and six first-class pens. Turbits and Fantails were well filled, and so good that many former prize birds only here obtained a card.

The Show closed on Saturday, a most inconvenient day for the return of the birds.

POULTRY.—DORKINGS.—Grey—1, H. Allen. 2, C. L. Boyce. 3, H. Brown. Any other colour—1, S. Newick. 2, Miss Strange. Cockerel—1, H. Brown. 2, G. Masters. Pullet—1, S. Newick. 2, Mrs. Radcliffe. 3, R. A. Baker. COCHINS.—Partridge—1, T. J. Saltmarsh. 2, Mrs. Radcliffe. 3, C. Marshall. Buff—1, Rev. J. Buckmaster. 2, Mrs. W. Paxton. 3, Mrs. H. J. Triton. Any other colour—1, J. Turner. 2, R. A. Boissier. 3, A. R. Buckland. Cockerel—1, Mrs. Radcliffe. 2, Dr. J. A. Hicks. 3, Miss Swann. Pullet—1, Mrs. Radcliffe. 2, Rev. J. Buckmaster. BRAHMAS.—Dark—1, Rev. J. D. Penke. 2, J. Long. 3, Miss Strange. Light—1, G. W. Petter. Hooked Dark—1, L. C. C. R. Norris. 2, J. Long. 3, Rev. J. D. Penke. Hooked Light—1, J. Long. 2, E. Durand. 3, G. W. Petter. COCKERELS.—1, L. C. C. Norris. 2, F. Chapman. 3, J. Long. PULLETS.—1, L. C. C. R. Norris. 2, G. W. Petter. 3, J. Long. GAME.—Black Red.—

Cock.—J. Mrs. H. J. Tritton. 2 and 3, W. Docksey. *Hen*.—1, T. Docwra. 2, G. H. Harnsworth. 3, J. Montgomery. *Duckwing*.—*Cock*.—1 and 2, W. Docksey. 3, F. Edwards. *Hen*.—1, W. Docksey. 2, T. LEEDS POULTRY SHOW.

This excellent annual Show was held on Tuesday the 11th, and two following days, in the Smithfield Market sheds. The great increase of entries has rendered the space at command far too small for the purpose, and it is contemplated to erect a grand hall for the Show, and this would be a great boon to both Judges and exhibitors, as the birds are at present placed three tier high, which in all cases places many at great disadvantage, and still the whole is managed in a most exemplary manner.

In poultry the *Game*, as usual, headed the list with a fine display; the winners were exceedingly well selected, the cup going to a grand Brown Red cock. The larger varieties were well represented, and the *Hamburgs*, of which there were more than one hundred pens, a show in themselves, the cup going to a capital pen of *Spanish* in the first-named section, although we have seen the cockerel look in better order. *Bantams* were excellent, the cup going to a splendid pen of Black Reds of this year.

In *Pigeons* some exhibitors' entries had been returned, as the entry fees had not been remitted with them (a rule we would recommend to the notice of other committees), and in consequence the numbers were not as large as we expected. *Pouters* headed the list; the first, a grand young Blue cock in splendid show, won the cup for the best bird in all classes; the second (a White) was a very showy bird. *Carriers*.—First a good all-round bird, but the rest poor. In *Short-faced Tumblers* Almonds won, but these were not as good as we have seen from the same exhibitor. *Long-faces* a grand class, perhaps the best we have ever seen. *Owls* poor except the first. *Jacobins* were very fine, the prizes going to a lot we have never heard of before. Both were Reds. *Turbits* were a puzzle, and were placed too high for a real thorough satisfactory inspection. The first a Blue and second a Red, counted pretty near perfection. *Fantails* good. For a thankless office commend us to judging a class of *Nuns* placed at such an elevation, every bird trimmed, and only a choice as to which is most perfect with least trimming. *Dragoons* very good; both the winners *Yellows*. *Antwerps* a bad lot; the best in *Short-faces* left out on account of excessive trimming, but the *Long-faces* were very good. *Maggies*.—The winners, Red, were excellent. *Swallows*.—First Red and second Black, both very good. The *Variety* class was a good one. First a *Fairy Swallow*, such as is rarely seen; and second a *Blondinette*.

Rabbits were a good entry, considering that so many other shows were held at the same time. *Lops*.—First a *Fawn*, good in all points and winner of the Society's medal; second a *Sooty Fawn*, one 23½ by 5½, and the other 23 by 5. *Silver-Greys* were very remarkably even and good. *Silver-Cream*—or, as for the future we shall designate them, *Silver Fawns*—were very good, and showed great improvement on all we have seen. The first the richest yet produced, but second better in silvering, and both very even in colour. *Himalayans* were very poor indeed. *Angoras* very good; the first a grand one, not only in quality but also in size. *Dutch* only five, but good, *Black* winning. *Belgian Hares* were an unusually even and good class, almost all deserving a prize, the winners leading mostly in ground colour and ear lacing. In the *Variety* class first was a very pretty *Albino*, and second a mongrel, very large. In the *Selling* class a *Silver Fawn* was first and a *Lop* second.

JUDGES.—*Poultry*: Messrs. Dixon and Teebay. *Pigeons and Rabbits*: Mr. E. Hutton.

Mr. E. W. Southwood has purchased the whole of Mrs. Arkwright's breeding and exhibiting stock of Dark Dorkings; and Mrs. Arkwright retires from the fancy.

A TRIAL OF HIVES SUGGESTED.

It will be remembered by some of your readers, that in the early months of this year a proposal was made with a view to test the powers of different kinds of hives and bees. It was then hoped that some gentlemen would come forward and lend their aid and advice in an effort to prove or disprove the alleged superiority of some kinds of hives and the Ligurian bees. In my opinion there is no other question stirring the bee-loving community of greater importance than this, and that if it can be lifted out of and above the region of mere opinion by a satisfactory trial a result very valuable will be arrived at. Hundreds of bee-keepers now want to know if some kinds of hives strongly recommended are really any better than those they already possess, and whether the Ligurian bees are really any better than the common sort. Who can at the present time give them the information they seek? What earnest honest bee-keepers want is a solid foundation of facts, and so far as we know such foundation has not been laid by the apiarists of either Europe or America.

Amongst the last importations from America was an Essay on bees by Mrs. Tupper, in which Ligurians are strongly commended. Though I do not attach much importance to her recommendations, she mentions one point which is new to most people—viz, that the bills or trunks of Ligurians are longer than those of common bees, and that this may be proved by filling a jar of honey covered with perforated zinc near both kinds of bees. After the common bees cannot reach the honey, the Ligurians continue to fill their sacs with it and carry it home. If this is a fact they possess one point of superiority. The main point is, Do they gather more honey? and this we have to find out yet.

Probably the hive last patented in America is one invented by Mr. N. C. Mitchell, Harrisburg, Pennsylvania, called "The Adjustable Bee Hive," which according to Mr. Mitchell's account beats all that the world has ever seen. He says his hives "are superior to all other moveable comb hives, and are so constructed that every idle bee can be set to work, and that

in them bees are five hundred per cent. easier handled, and gather four hundred per cent. more honey than they do in other hives. This adjustable hive is the only one that will winter bees in any latitude without loss. Its price is only 75 cents. We have been selling townships at 25 dols., and counties at from 100 to 200 dols." He means the right to sell his "Adjustable" hives in townships and counties. It is to be regretted that such extravagant statements are ever made, and that any bee-keepers are so gullible as to believe them. Even in this England of ours it was stated by a gentleman this year, that owing to the materials and construction of a hive in his garden it gathered three hundred per cent. more honey than a straw hive standing beside it, and doubtless some believed him.

With a view to enlighten public opinion and advance apiculture I shall leave to suggest that next year (1878) we may have a test trial or friendly competition between Italian and common bees and hives of different kinds. It appears to me that an enterprise of this kind will be of great advantage to the bee-keepers of this and other countries. All the reading public of England would be put into the jury-box to see and hear for themselves. The story of the trial would be told in every place, and truth would prevail. If three or four or more gentlemen on either side or different schools will undertake to provide four or six hives for trial it would be easy to make arrangements for a public competition. The conditions should be left to a committee and be discussed by the public. By reason of the weight of years resting on me I am not so able and active as I once was, but if no younger man comes to the front with common bees and straw hives for the proposed competition I will find some in my own garden and willingly send them to the arena of contest; and I earnestly hope that some of our friends on the other side will have the courage of their opinions and be ready to appear with the Italian bees and hives after their models. In such a trial honest men have nothing to lose but much to gain. The best hives and best bees would be put into the top class by general consent. In all honourable contests and discussions those that lose the day are the greatest gainers, for they gain truth by defeat, and truth is better than victory.

As this is the last effort I shall make to bring about a public competition of bees and hives I should like it to be successful. I rather fear that some of our friends may not like to venture their bees in a public trial, and some others would not part with theirs for a season. Hence I am going to take a liberty by asking ten or twelve of our friends to promise £1 a-piece to help to carry out our proposal of testing in a satisfactory manner the powers of some kinds of hives and bees. I do not want to touch a penny of money, but in the event of no one appearing with Ligurians to prove their superiority, that three or four hives of them be purchased for the proposed trial. If arrangements be made for trial next year, and the season be favourable for honey-gathering, the bees of eight or ten strong hives would gather honey enough to pay all the expense and cost of purchase. I commend the consideration of the proposal to the bee-keepers of Great Britain, believing as I do that a trial of the kind would do more to advance apiculture than many bee and honey shows, and at much less expense.

If we can see our way to secure the hives for the enterprise satisfactory conditions would be arranged afterwards. I am quite sure that we have in the bee-loving community means and energy enough to carry out the suggestion to a successful issue. It is a question for the multitude, and the greater interest will be excited if many people take part in the undertaking. I shall be glad if the readers of the Journal will give us their opinions and aid.—A. PETTIGREW.

LARGE v. SMALL HIVES.

I HAVE no sort of wish to do injustice to Mr. Pettigrew, nor did I think I had done so. Perhaps if I had written "he has frequently admitted that he has little or no personally practical experience of the management of bar-framed hives," I should have expressed myself more accurately. Such certainly was what I meant to convey.

As to my "reckless" statement, I shall not "squabble" with Mr. Pettigrew about it. Nevertheless, it is a fact of my own experience, and I must adhere to it. I have no doubt that "wherever honey can be obtained large strong hives gather it faster than strong small hives." All I say is, there must be honey in sufficient quantity to fill these large strong hives, otherwise the bees will waste both energy and honey in making an unnecessary quantity of comb, which will not be the case in smaller and compact hives. Having tried both larger and smaller hives in this poor honey-gathering district I again repeat that "I have abundantly proved my statement to be true."—B. & W.

OUR LETTER BOX.

DORRING COCK DIARRHOEAED (J. S. T.).—The cock is suffering either from unwholesome food or from imperfect digestion. In either case it is necessary

that purgatives should be administered in order to get rid of that which offends. Acting on that which you assure us to be the case, that the bird, except as regards his comb, is in perfect health, we should at once administer a good tablespoonful of castor oil, and after that had operated we would give some stale crusts soaked in strong ale and a couple of pills of camphor the size of a small pea. The colour of the comb should then begin to return. If it does not after two or three days repeat the dose.

RICE MEAL FOR FOWLS (M. B.).—We are very sorry our experience does not tally with that of your friend. We hold rice to be useless food in every shape and form. We have tried it not only with poultry but with game and pigs. The fat put on disappeared at the fire, and the lean of the flesh might have claimed relationship with indiarubber. It is needless to say that in such condition there cannot be good plumage. We have always found rice to be so poor in itself that it is favourable to the production of parasites. It has always done so in our trials. Feed on barley meal or ground oats slaked with water morning and evening, midday give barley or maize or kitchen scraps. If your stock is as good as that of your friend, if the eggs are set at the same time and the chickens equally cared for, we do not hesitate to say you will beat the rice.

PRICES OF RABBITS (E. M. F.).—Two such Rabbits as you describe can be put on board a New York steamer in a proper hutch for £5 10s. This sum would not include food.

BEES IN TOWNS (Lex).—By intelligent management and judiciously feeding the bees a fair amount of success is attainable. We shall shortly publish an instance of successful bee-keeping in London.

REMARKS.

12th.—Boisterous and wet in the early morning, but fine by 9 A.M., and sunny after 10 A.M.

13th.—Bright sunny day but cold; fine night.

14th.—Fine morning, with thick white frost; fine and bright all day.

15th.—Morning misty and cold, sky overcast most of the day; but a lunar halo visible at 6 P.M.

16th.—Generally overcast, but a pleasant day; rather windy in afternoon; moonlight evening.

17th.—Misty morning but fine; rather dull all day; finer at night.

18th.—Very fine and bright throughout, with very high barometer.

A dry fine week, with high barometer. Westerly wind and very little rain.—G. J. SIMONS.

COVENT GARDEN MARKET.—DECEMBER 19.

THIS being Christmas time a little more activity is displayed in our Market but as a rule prices are not what might be expected. Pears are making high prices, but there is no improvement in the value of Apples. Kent Cobs are higher.

From observations taken near London during forty-three years, the average day temperature of the week is 43.0°; and its night temperature 32.8°.

SOME LESSONS OF THE YEAR.

FAREWELL to the old year, for it is passing away, a few brief hours only remaining to us before the tale of its days will be complete and it will be numbered with the past. This is the thought which comes to me as I sit down for the last time this year to write a few notes for our Journal, and so it seems most fitting that my theme should be a retrospective one; for undoubtedly now is the time to review the lessons of the past twelve months, and endeavour to turn their teachings to account so far as may be practicable in the coming year.

January opened mild and wet. A maximum temperature full 10° above the average mean of winter was registered, and such dripping weather prevailed that autumn-sown Peas were forced into premature growth by the remarkable mildness of the weather, and became so weakly as to succumb to the almost incessant wet; Strawberries too suffered severely, whole beds being killed outright, thus showing that a very wet winter sometimes proves as fatal to vegetation as a very cold one. The mild weather continued till the last week in February, when we had some snowstorms and a decided change to colder weather, there being 12° of frost on the 28th of that month. March was a cold month with a succession of frosts, inducing us to hope that fruit trees, teeming as they were with flower buds, would be so much retarded as to be safe from spring frosts; but our hopes were doomed to disappointment, for we had a repetition of those bitter cold north-eastern gales which so frequently occur just as the opening blossom and expanding foliage are most liable to suffer from such adverse influences, the result being that the bulk of the fruit crop was lost, and blistered foliage of Peach and Nectarine trees was so prevalent as to convince the most sceptical that cold, and cold alone, is the cause of blister. The foliage was so badly affected that almost the whole of it fell off prematurely, giving a severe check to the spring growth which all good cultivators of the Peach like to see flourishing in full vigour, knowing as they do that a strong early growth points to full and early maturity in autumn. This failure of the spring growth and the miserable sickly condition of the trees rendered the subsequent vigorous shoots of midsummer all the more remarkable, for in a week or two the trees were fully clad with large green healthy foliage, and the robust growth sprang forth with such rapidity and freedom as to afford a striking illustration of the vigour of healthy Peach trees. Very little of the fruit survived this rude assault of untimely cold; in fact much of the blossom never came to maturity, the ground being strewn with half-developed buds—a sight most melancholy to behold, a failure most lamentable, for the trees were full of promise, and hopes of a full crop of fine fruit were proportionately high. The failure was not a mere local affair, but was general throughout the country, and I for one frankly confess that my

views of Peach culture have undergone considerable modification.

Let me be consistent and remind my readers that I have repeatedly appeared in these pages as the warm advocate of Peach culture upon open walls, and I have still no reason to doubt that in most years the trees will yield a good crop of fruit; yet there will always be the risk of failure from ungenial spring weather, and therefore in all large gardens, which it may fairly be said are made with a view of securing an unfailing annual supply of fruit in its season, the trees should have the protection of glass houses of the most simple form and inexpensive materials compatible with efficiency. Before turning from the fruit I must call attention to the important fact that while the Apple crop generally was a failure, yet Cellini Pippin, Wormsley Pippin, Small's Admirable, Margil, and Duchess of Oldenburgh all had good crops, notwithstanding that the trees were fully exposed; Cox's Orange Pippin and King of Pippins having about half a crop.

Vegetables have been abundant and good. Potatoes did not altogether escape the ravages of blight, yet the past season has again afforded conclusive proof that early lifting is the only safeguard against disease. The whole of the early sorts were quite sound, and not a tuber of the late kinds lifted before the heavy rains fell in August was affected; but unfortunately we were overtaken by rain before the lifting was finished, and many of the tubers subsequently taken up were affected, as has always been the case. This, however, valuable as is the experience it affords, is only one of the evils resulting from unfavourable weather. A cold, late, wet spring brought many trials in its train—that terrific gale from the southwest on the 28th of May left the mark of its scathing power till the leaves fell in autumn, the foliage of Larch Firs having a scorched appearance as if it had been subjected to the action of fire; and Beech trees, with very few exceptions, had their leaves so much battered and lacerated as caused the trees to present a disreputable browned ragged appearance.

I am in no humour to enlarge further upon the *per contras* of a season that has on the whole proved fairly prosperous. Trials and difficulties are part and parcel of our lives. Met in the right spirit they may generally be overcome and often so turned to account as to lay the foundation of subsequent success and prosperity. The old school maxim, "Perseverance conquers all things," not only holds good but seems to me to become increasingly significant as mature experience enables one to understand cause and effect more clearly, and to see that application and painstaking is after all the secret of success. In view, therefore, of that progressive improvement which should end only with our lives it will be well to turn to account the few hours of the old year which remain to us by a calm and thoughtful review of our individual failures and shortcomings, and thus make ready to enter upon a new year with earnest healthy resolutions to strive for improvement in all we undertake; for sure I am that such resolutions give such an impetus to our

efforts as enables us to enjoy that which I heartily wish every reader of the Journal—

A HAPPY NEW YEAR.

—EDWARD LUCKHURST.

POTATO DISEASE.

WITH much surprise and some pleasure I have read the articles by "AMATEUR" on "Speculations as to the Nature and Origin of the Potato Disease." Predisposing influences no doubt there are, but these must not be confounded with the cause of the disease itself, which it can scarcely be delusion to believe is now clearly attributable to *Peronospora infestans*, known as the Potato fungus, perhaps not the only one to which it is liable or which may help sometimes to produce the condition of disease. Why should there be any speculation when authorities who investigate bring forward the result of their research? Further research surely is the only thing admissible on which to form an opinion. The writings of well-known scientific men give evidence of the above cause, and this we must assume to be trustworthy. I cannot recall any investigator who has reached any but this accepted conclusion. That everybody is not convinced is of no consequence. The subject is of such a nature that few comparatively are in a position to say from immediate observation whether a fungus is the cause or not. There are those who will not or cannot accept an evident fact. A strange doctrine is not easily received or criticised by those who have no knowledge by which to compare and grasp the new theory or fact. Many absurdities have come from those who read to no purpose or do not investigate for themselves. The word "investigate" is used in its full meaning. In this case it implies the use of the microscope as a preliminary, an instrument which "AMATEUR" does not appear to have used; yet inclining as he does to the fungus it might, with the help of a little further experiment, place the matter to his mind beyond the region of speculation, where it is, I believe, to the minds of the majority of those who are worth attention.

"AMATEUR" says that "an able botanist not long ago came out with the astounding statement that everybody was convinced that the fungus was the disease." This, he says, is going a little too far. We have already disposed of "everybody." Everybody does not believe in the rotundity of the earth even in this year of grace. Then as to whether it is in the least degree astounding that a fungus should produce disease, "AMATEUR" does not say that it is, and may not think so. But why review the several speculations when he is inclined to believe in the fungus, if there is not some difficulty? He can scarcely fail to find that it has the best support, and if so it is the first thing to follow up. What wonder need there be? It is well known that plants are frequently the hosts of other and usually lower forms of vegetable life, very commonly a fungus. Mistletoe grows on the Apple tree; seeing which with the naked eye, we believe and have no difficulty. It might be called an Apple disease. Innumerable instances may be cited of all kinds of parasitism down to the attack of a roadside weed by a fungus. The case of Mistletoe on the Apple is truly analogous so far that the one is a parasite destroying more or less the other. That the fungus is microscopic does not render it a less likely cause. Nature is great in the infinitely little, and much of the highest importance may there be found. We are told of organisms which the strongest microscope is unable to make visible, yet they live and have their being: this on the authority of Prof. Tyndall, to whom "AMATEUR" refers, about which we shall presently speak. *En parenthèse* we may remark that these organisms are known of course only by scientific deduction. Vegetables growing on vegetables are common enough, but are less wonderful than the cases of vegetable parasitism on animals, the human race even being liable to the attack of a fungus. "Favus" is a disease caused by the attack of *Achorion Schoenleinii*, which attacks the part of the human head covered with hair, into which the spores grow, producing complete and permanent baldness. We have to believe a great deal that does not appear possible at first sight. The skin of a pig—it cannot be well known—will graft on the human flesh. This is rather revolting, but necessity knows no law. It has been used in a case, when the supply of human skin failed, for the purpose of covering a surface on which the natural skin could not grow. It has nothing, whatever, of course to do with Potato disease, but is useful to mention while we have probabilities under discussion. A number of different forms and

species of fungus are known which inhabit the body of the living animal. Instances need scarcely be given. Suffice it to mention *Botrytis Bassiana*, an ally of *Peronospora*, which causes the muscardine disease so destructive to silkworms; *Sphaeria Robertsii* of New Zealand, which grows from the head of the larva of a moth, itself 2 inches long or little more, and the fungus 8; and the Chinese *S. sinensis* on a caterpillar, having the interest of being used as food. All this being true there is nothing more natural than a fungus affecting the Potato even to destruction.

"AMATEUR" steps within the bounds of medical science for illustration and takes the measles, not appearing to be aware that infectious diseases do not always result from infection. Given the necessary conditions and the disease may appear, then forming a centre of contagion. This would be true for measles if we accept the theory of the glandular origin of such diseases, and may be so in any case; but whether Adam so suffered or not must always remain an open question. Probably, if he came within the conditions, he did (some one started with that affliction); then possibly Eve had them by infection. Eve first ate the forbidden fruit, perhaps she first had the measles in consequence. I fail to see how the "if not" and "why not" would be worth the attention of a medical student.

"AMATEUR" next speaks of Professor Tyndall and spontaneous generation, but there falls into error. Professor Tyndall's experiments go to prove that the spontaneous generation theory is untenable, not the reverse. "AMATEUR" does not believe in it, and appears to be right; but how does he reach his conclusions? Not, it would seem, by deduction from the experiments of others or by his own research. Speculation or opinion will not do for this or Potato disease so long as either can be brought under investigation.

Much of the speculation reviewed must be passed over in a body, not according, as it appears to me, with the light of present knowledge, and therefore my remarks must be limited to that which bears on *Peronospora*. Degeneracy* (debility), atmospheric influences, &c., may no doubt place the Potato in a position less able to withstand the attacks of its enemy, but, this enemy absent, no amount of "degeneracy" or anything else will produce its effect. The development of this disease appears to show that the fungus is the cause and not the consequent. It has been placed before us by authorities who have investigated carefully, and therefore must be accepted by all who do not probe the matter as fully themselves. With regard to spread, it must be remembered that the fungus has been supplied with the conditions of increase by cultivation of its host, the Potato. This disease and others of a like kind to which economic plants are liable must be taken as the penalty man has to pay for cultivating their subjects in masses, and he must therefore accept the net result. Plants are widely affected in a state of nature, but then are comparatively isolated. Often are flowering plants introduced to other countries on conditions, where they attain a development unknown in their original habitat. Very likely it is also the case with certain fungi. Possibly the *Peronospora* grew on another plant altogether, whether in this country or another, but in the Potato found a host more agreeable to its requirements. "AMATEUR" says very little with regard to origin, and it is in the above sense no doubt he intends the word to be taken. Very little indeed can be said, or rather nothing at all, till it is found truly and certainly wild.

To trace the fungus through past time is no doubt an impossibility. We have knowledge, however, thus far, that countless ages ago it may have existed in much the same form as now. The oldest fungus on record has not long since been discovered, and it is a remarkable fact that while similar in other respects its zoospores are the same in form and dimensions with those of *Peronospora* when measured to the ten-thousandth of an inch. This is the fossil *Peronosporites antiquarius*, found in the vascular structure of the axis of *Lepidodendron*, one of the gigantic Club Mosses of the carboniferous epoch.

"AMATEUR" does not in precise words define his theory, but from his illustrations it appears to be that of an organism coming from somewhere—in any case a parasite. What, then,

* This word must here be used with a limited meaning. It cannot be admitted with the sense that a variety of a plant propagated by extension of an original individual "runs out" by long cultivation, as has been said of the Ribston Pippin and other fruits. Whether they know it or not, people generally mean a functional disturbance or weakness, which may result from a variety of causes.

can the introduction of a flowering plant not a parasite have to do with the matter? If of any import the fact only need be mentioned, for such cases are well known, and others of very rapid spread besides *Anacharis*. It is difficult to be seen what inferences can be drawn from the history of *Phylloxera* or the Colorado beetle when (if I am right) the disease has never been attributed to an insect. Whether of animal or vegetable life, however, it is a not uncommon occurrence for rapid spread to take place in a new country. While "AMATEUR" has brought together and reviewed a variety of speculations, it is not a little surprising that no mention is made of the writings of Berkeley, De Bary, Worthington Smith, or others who have investigated. An ounce of investigation is surely worth many pounds of speculation or theory.—*PERONOSPORA*.

ANNUALS.

SOME years ago, before the bedding-out mania had attained to the dimensions it has done, annuals received a great deal of attention, but of late it is difficult in many gardens to find even the very commonest. The fragrant Mignonette and Sweet Pea are sometimes not thought worthy of a place, and a scentless garden from whence not a breath of perfume arises is no uncommon thing. You may pass furlongs of ribbon bordering, bed after bed of carpet fashion, arranged in the most elaborate and fantastic patterns, but from them all not one delicious sense of scent arises; and it is the same of course when the flowers are cut for the house. Oftentimes the nosegay or vase of flowers is tastefully arranged, but the want is felt; for how involuntarily when one gets near a bunch of flowers does the face go down to catch the delicate perfume, which in so many instances is not to be found. For this reason, then, I would say a word for annuals. But there is another: They afford so much variety in form and colour, that not only do they please the eye when growing in the garden, but also add an elegance and lightness to a vase of flowers which the more formal trusses of Geraniums and other plants used for bedding-out do not afford. Take, for example, one of the very commonest—*Coreopsis*; how much of elegance do a few of its brilliant-coloured flowers give to a vase, and how easily are they to be had! In these notes I would, then, plead for them, especially as skill and enterprise are continually adding novelties to our lists.

There is little need now to advocate the cause of herbaceous plants, they are steadily working their own way once again into favour; but it is at the same time desirable not to overdo the addition. I do not think that by a mixed border we are to understand simply a collection of herbaceous plants. No: I think fairly enough we may include in it bulbs in spring and autumn, and annuals and Geraniums in the summer months; if the latter, not enough to make their growth a burden or inconvenience in the winter months. What I mean may be ascertained by going into many greenhouses at this season where you will find them full to overflowing with store pots of Geraniums, *Heliotropes*, &c., instead of plants in which cultural skill can be displayed and varied forms of beauty beseen.

The exhibition of annuals held by Messrs. Carter & Co. of High Holborn at the Royal Botanic Society's gardens this season must have opened the eyes of a good many to the forms of beauty they have neglected in their rush after some novelty for bedding-out; and in the hope of inducing some of the readers of the Journal to give a small place in their garden to some of the best of these I would select those which I have tried in my own little garden, and which have been useful either for showiness in the borders or for cutting.

Carmine Candytuft.—A very pretty form of this old and well-known favourite flower with rich carmine flowers.

Calliopsis bicolor, atrosanguinea, &c.—Very common, but very useful for cutting, especially for the top glass of dinner-table stands.

Chrysanthemum tricolor, Burridgi, Dunnetti, &c.—These annual *Chrysanthemums* are very pretty and striking in appearance, enlivening a bouquet very much.

Dianthus chinensis Heddwigi.—There are several forms of this pretty and quaint flower, and two have been exhibited this season by Messrs. Carter & Co.—viz., *Easter Queen* and *Crimson Belle*, which are a great improvement on previous varieties.

Godetia Lady Albemarle.—A very beautiful novelty, having flowers 4 inches across and produced in the greatest abundance; the colour a beautiful crimson with a bluish tinge on the edges of the petals.

Leptosiphon roscus.—A charming little plant, so dwarf that it may be grown upon a rockery amongst Alpines, and so bright that it lightens it up wonderfully.

Phlox Drummondii.—A wonderful improvement has taken place in this most useful plant. The size of the flowers has been increased; and in the compact varieties—*nana compacta*, rose, red, white, and violet—the Messrs. Carter have overcome one of the greatest objections to them—their loose and straggling habit. These flowers are alike useful to those who have a mixed border or who go in for bedding-out.

Portulaca, Single and Double.—These are very pretty, but do best when in some poor soil with a good deal of lime rubbish or burnt earth. If the situation is favourable they will seed freely and renew themselves yearly.

Silene pendula compacta.—A very compact-growing form of the old *Silene pendula*, and during the flowering season is one solid mass of bloom.

I must also refer to a very useful biennial—*Campanula Medium calycanthema*. A very striking form of the old Canterbury Bell, introduced by Messrs. Waite, Burnell, & Co., some years ago. Very fine and striking in appearance.

In what are called German flower seeds there has also been great improvement. What more delightful than a good bed of some of the many varieties of Ten-week Stocks? And then for autumn how fine and useful are our old friends the Asters! while for brilliancy of colouring we have the very handsome forms of double *Zinnias* and the African and French *Marigolds*. Mr. Betteridge's Asters with their exquisite forms are very valuable. Annual Larkspurs have also been greatly improved; and the candelabrum, dwarf Stock-flowered, and Emperor varieties are especially good. Then of the older annuals the scarlet Flax, the many varieties of Lupins, *Schizanthus*, *Nemophila*, &c., will readily occur to any who have taken an interest in gardens, and it will be surely worth while to renew their acquaintance with them.

A garden of this mixed character never fails to have some point of interest, and, as some one says, there are always surprises. Things you had forgotten peep up; flowers you had thought were over give you a bloom now and then unexpectedly. Your beds are never quite empty; and even in the depth of winter, when days are short and clouds dull, you may find something; as, for instance, going round this morning (December 11th) I found a fine spike of *Schizostylis coccinea* in full beauty, and the earlier varieties of *Cyclamen* just beginning to show their bloom, and *Crocuses* beginning to peep up. Expectations are quickened, and you have a sense of pleasure in the thought that your garden is even now a thing of beauty, and that it is continually returning to you something for the care and love you bestow on it.—D., Deal.

GOOSEBERRIES.

THEIR PROPAGATION AND CULTURE.

THE Gooseberry is a native of the north of Europe. In a wild state the berries are no larger than a Red Currant, but when the bushes are properly cultivated immense crops of large fruit are produced. The Gooseberry is one of the few fruits which succeed in any soil or situation, consequently it is grown, but not cultivated, in every garden. Owing to the bushes producing fruit without any attention they are frequently never touched, except, perhaps, with the garden shears; yet even when thus neglected they produce plenty of fruit, but it is of a very inferior description.

The Gooseberry is one of the easiest of all fruits to propagate, and the present season is the time to do it. When pruning the bushes select all the strongest shoots made during the summer, cut them 1 foot long each. Begin at the bottom and rub all the buds off excepting four at the top; leave the spines on, as they assist greatly in keeping the cuttings in their places when they are inserted in the ground. A quantity of leaf soil or well-decayed manure must be spread over the surface. Insert the rows of cuttings as the digging proceeds. A space of 15 inches should be allowed between the rows and 4 inches between the cuttings. Let the cuttings be 4 inches below the soil, which will leave 5 inches of clear stem between the ground and the first branch. We have raised many Gooseberries in this way without losing a cutting. They must not be disturbed at the root until the following spring. Throughout the summer hoe between the rows frequently, and never allow them to become choked with weeds. They should make shoots from 4 to 6 inches long the first season. Where the cuttings were all disbudded

excepting 3 inches at the top each plant will produce from four to six shoots. When pruning these, as soon as the leaves have fallen only cut about 1 inch from the point of each shoot. After this, if it is desired to make large bushes quickly, lift every other plant in the row, and plant them in a fresh piece of ground 18 inches between the rows and 10 inches or a foot between the plants. The ground on which these are planted should be well enriched with manure. During the second year's growth hoe between the rows as formerly, and by pruning time the second season you will have good-sized bushes. When the shoots are clustered together in the centre they must be thinned out to be at least 2 inches from each other; but do not cut off any that are spreading outwards, as this is just what is wanted to form a well-shaped bush. All the shoots left on at this time may be cut back to 6 or 8 inches from whence they started.

After their third season's growth they may be pruned as before, and then they will be ready for planting in their permanent fruiting quarters. They may either be planted in a single or double row along the sides of walks or in one of the garden quarters. In either case the ground should be trenched 2 feet deep, incorporating with it plenty of manure. Supposing the ground to have been prepared in November or December, the bushes may be planted in January, February, or March when the ground is free from frost. At this time the bushes should be planted at the least 4 feet apart each way. Make the holes large enough to let the roots in easily, press the soil firmly about them, and place a strong stake to each if the situation is exposed. Nothing but hoeing is required to be done to the soil for twelve or eighteen months after the bushes have been planted, but never let a winter pass without pruning them carefully. Always keep the bush in good shape. Never leave the wood crowded. When the bushes have attained their full size cut the young wood close in to the old stems annually. When they have grown in the same soil for four or five years, after pruning spread some good manure all round the stem and over the roots, and fork it lightly in. Do this annually. When the bushes become old and the branches begin to moss-up and die root them out and plant young bushes.

As to varieties, I cannot name better sorts than those given in the list of hardy fruits in last week's Journal. Where many are wanted for preserving grow the red sorts for this purpose. Where dessert is the object grow white, yellow, and green kinds. Apart from the uses to which they may be put when gathered off the bushes, they may be bottled in a green state and reserved for this season of the year. We are using some now which were bottled in June, and very acceptable they are for tarts. Various kinds of caterpillars are most destructive to the Gooseberry. Nothing proves such an effectual cure for them as gathering them with the hand. We always keep our bushes perfectly clean by looking over them frequently from the time the leaves are formed until the fruit is ripe. Birds are troublesome when the fruit is ripe, but old nets are cheap and prove an effectual safeguard.—A KITCHEN GARDENER.

HARDY RHODODENDRONS FOR CONSERVATORY DECORATION.

HARDY Rhododendrons for conservatory decoration during the early months of the year form very fit associates to the hardy Azaleas which were referred to in an excellent article on page 449. The great variety of colour possessed by Rhododendrons—some of them gorgeous, others delicate—render those shrubs most valuable. They are also so easy to force that they become almost indispensable for indoor embellishment during early spring.

Small and moderate-sized plants which are well set with buds are the most suitable for this purpose, for when they have grown very large it becomes necessary to reduce their balls to such an extent in order to get them into available-sized pots, that the plants are permanently injured. Suitable sized plants for forcing are always to be obtained at very reasonable prices at our leading nurseries, and if the selections are left to these firms plants suitable for the purpose required can be relied upon. I append a select list for those who may prefer to choose for themselves. The sorts named are free bloomers, and are otherwise attractive and useful.

Having secured the requisite number of plants place them in pots as nearly as possible of the same size as the balls, retaining as many of the very fine fibrous roots as can be secured. If

the weather is at all open they may be placed out of doors, but it is much safer to afford them the protection of a cold house or frame until they are wanted to be forced. An intermediate temperature of about 50° will be found very suitable for starting them, and if required to be pushed faster a stove temperature does not injure them so long as a moist atmosphere is provided and the plants are well syringed, giving the roots at the same time a plentiful supply of tepid water.

Rhododendron Nobleanum and its varieties are forced with the greatest ease, but those that are later in blooming out of doors in an ordinary way will take a longer time to expand their gorgeous blooms of scarlet, crimson, and allied colours indoors. If when they are fully expanded they are removed to the conservatory they will remain in bloom a long time, producing an effect that cannot be surpassed by any other flowers. Remove the flowers as they decay, and keep the plants under glass until mild weather ensues, when they may be transferred to the borders or to a piece of ground in the reserve garden to recruit themselves for future occasions. It seldom happens that the plants are suitable for forcing the second year, but the third and subsequent years they will be generally set with sufficient flower buds for that purpose.

Of the early-flowering sorts the following may be selected:—*Altaclarensis*, dark scarlet, very fine; *Blanche superbe*, pure waxy white; *Broughtonianum*, rosy red, immense trusses and fine foliage; *Cardinale*, scarlet; *caucasicum*, a very profuse bloomer of a yellowish colour; *Coriaceum*, white, dwarf habit, and a free bloomer; *Desdemona*, very richly blotched with dark on the upper segments, the lower petals being almost white; *Limbatum*, white, margined crimson; *Madame Wagner*, bright pink, white centre, a very pleasing and effective variety; *Nobleanum* in several varieties are all good for early work; *Ochroleucum*, very distinct, of dwarf habit, and pale yellow colour; *Regale*, scarlet and rose; *Rubescens*, bright ruby red and distinct.

Of the later blooming varieties *Alarm*, *Auguste Van Geert*, *Baron Osy*, *Blandyanum*, *Brayanum*, *Hendersonii*, *Jenny Lind*, *Leviathan*, *Lord Clyde*, *Lord Derby*, *Lord Russell*, *Madame Titiens*, *Madame Van de Weyer*, *Marian*, *Mirabilis*, *Miss Buller*, *Mrs. John Clutton*, *Neilsoni*, *Onslowianum*, *Prince Camille de Rohan*, *Princess Amelia*, *Purity*, *The Grand Arab*, and *Verschaffelti* are all good sorts, and most of them are generally to be met with in outdoor collections.—J. W. MOORMAN.

PICEA NOBILIS SEEDLINGS.

To a question asked by your correspondent Mr. Walton in reference to seed of this Conifer having been grown in open air without protection, I can state that when sojourning in South Devon my usual practice was to sow seed of *Abies Douglasi*, *A. nobilis*, &c., in sandy soil properly prepared in spring, making drills 2½ inches deep and a foot apart, the seed being sown in the same way that Peas are sown and in equally exposed places. In due course the seed germinated, and thousands of seedlings appeared. The only after-care for the first year was keeping the ground clear of weeds. In the second spring, if the plants have made satisfactory progress, have them all very carefully lifted and replanted in good sandy soil about 6 inches apart and 15 inches from row to row. If skilfully managed many of them will be fit for removal to permanent positions in the third year after sowing. Take precaution that rats or mice do not eat the seed, which they will do if hungry. A sprinkling of powdered rosin or red lead on the seed after it is slightly moistened will act as a deterrent. A very slight application of paraffin oil will also answer the same purpose. Where seeds of Conifers are not plentiful the better way will be to sow in shallow boxes well drained, and in prepared soil, placing them in a cold frame or pit near the glass, carefully attending to the soil being kept in a proper state of moisture.

In closing, will any of your correspondents inform me if they have raised *Wellingtonia gigantea* from home-saved seed? An answer in the affirmative, adding how it has been accomplished, will be interesting to your numerous subscribers and also to—ROBERT BEBBIE.

GLAZING WITHOUT PUTTY.—Mr. Laycock has furnished a lucid description of the rafter required for glazing without putty. Will he favour us with a more simple description of how the glass is fixed? Does he intend that the rubber is

laid on the glass, the screw then passing through the rubber, thence into the rafter? If so, should it be placed at the bottom of the pane?—J. R. COOPER.

ARECA PURPUREA.

THE *Areca*s constitute an important genus of a beautiful family. *A. Catechu* is the Betel-nut Palm, and *A. oleracea* the Cabbage Palm. It is, however, not on account of their products that Palms are valued in this country, but it is their stately elegance of growth and their adaptability to various decorative purposes that renders them so deservedly popular. Mr. B. S. Williams of Holloway states that he raised this Palm

Failure may be due not to some one particular condition, but rather to a combination of circumstances, which it would be difficult to satisfactorily elucidate. The only really sound advice that can be given in case of canker is to discard the trees liable thereto and replace them with those found to succeed.

I have Ribston Pippin and Hawthornden Apples both on Crab and Doucin stocks, and the trees not only canker badly but the fruit is so much spotted, and in a wet season cracked as to be useless. I have lifted them, changed the soil, but only with a very slight improvement, and nothing further, so far as I can see, remains to be done but to clear them out. Equally cumberers of the ground are Louise Bonne

Fig. 91.—ARECA PURPUREA.

(fig. 91) from seeds sent from Madagascar. He describes it as an elegant neat-growing Palm; leaves pinnate; the stem and petioles are of a bronzy purple colour, which makes a very striking contrast to the pleasing green colour of the leaves. It is very distinct, at least in the small state, from any Palm in cultivation; and on account of its dwarf and compact habit, and graceful appearance, will be found to be admirably adapted for dinner-table decoration.

FRUIT NOTES.

FRUIT crops were rendered extremely scant, even in the case of many trees worthless, by a few nights of rather severe frost, but surely other influences must have contributed in some degree to so general and complete a failure; indeed, I attribute more of the cause of the failure to the wet and cold previous autumn than to frost in the spring, the wood not being sufficiently ripened. Canker of the wood is a great enemy to full fruit crops, and it is nearly as common as frosts in spring.

of Jersey, Beurré d'Anjou, Beurré Brown, and Beurré d'Aremberg Pears. They are on both Pear and Quince stocks, and against walls as well as in the open with a similar result. Passe Colmar, Easter Beurré, and Beurré Superfin, the latter in the open only, are no good in this cold exposed position; the trees canker, the fruit pits and cracks. Beurré Superfin against a wall is contrariwise good. An election of fruits constitutes a valuable index to the planter, but it is not sufficient for all persons and positions. Then I am troubled with kinds that do not afford profitable crops. It is not a consequence of injudicious selection but of unsuitability of soil or situation, or both. Blenheim Pippin stands high in the election, but my trees have not given any fruits worth mentioning; yet Cox's Orange Pippin fruits abundantly. Surely pyramids 10 feet in diameter at the base and as much in height ought to do something. They are very healthy, very much nobler-looking than others that produced more fruit the year after planting than the others have yielded altogether. Beurré Hardy Pear, though it makes an imposing pyramid and has a noble appearance against a

west wall, has not given fruit corresponding to the years planted, and British Queen, which I much long to see, fails to afford a specimen. Surely these, and some others which I need not name, will some day amply reward the patient waiting and longing for fruit.

The Apples that do well here are Keswick Codlin, Lord Suffield, Emperor Alexander, Cox's Pomona (three-year-old bushes from the graft on Doucin stock gave this year over twenty full-sized fruit), Cellini, Warner's King, Holland Pippin, Hollandbury, Dumelow's Seedling, Bedfordshire Foundling, Yorkshire Greening, and Northern Greening. I have the Greasy-coat (Russian Transparent), which never fails to fruit, being trained as a horizontal espalier. Lady Henniker promises well. Dessert Apples doing well are Joanneting (White), Irish Peach, Red Astrachan, Devonshire Quarrenden, Kerry Pippin, King of the Pippins, Court of Wick, Cox's Orange Pippin, Margil, Reineette du Canada, Dutch Mignonne, Duke of Devonshire, and Sturmer Pippin.

Pears have not only been a poor crop, but indifferent in size and quality. I will name a few that succeed:—Doyenné d'Été, Jargonelle, Clapp's Favourite, Williams' Bon Chrétien, Beurré d'Amanlis, White Doyenné, Comte de Lamy, Seckle, Doyenné du Comice, Marie Louise, Thompson's, Beurré Diel, Zephirin Greigroire, and Bergamotte Esperen. Those are in the open, as well as Catillac, the best stewing Pear. Against walls:—Jargonelle, Beurré d'Amanlis, Gratioli of Jersey, Beurré Superfin, Hacon's Incomparable (this was the fullest in crop and best Pear of the year), Marie Louise, Beurré Diel, Beurré Bachelier, Passe Colmar, Knight's Monarch, Winter Nelis, Joséphine de Malines, Bergamotte Esperen; and Passe Crassane, General Todleben, Beurré Langelier, Napoleon, Jules d'Airolles, Dr. Trousseau, Glou Morcean, and Beurré Rance all do well.

Plums have been scant, and the fruit cracked when ripening. Early Prolific, Orleans, Mitchelson's, Victoria, Winesour, and Crittenden or Farleigh Damsen are culinary Plums succeeding in the open. Dessert Plums succeeding in the open are De Montfort, July Green Gage, Oullins Golden Gage, Green Gage, Jefferson, and Kirke's. Against walls—Green Gage, Jefferson, Transparent Gage, Kirke's, and Cos's Golden Drop are the best of dessert Plums; and Victoria, Prince Englebert, Prince of Wales, White Magnum Bonum, of culinary sorts.

Apricots ripened very imperfectly. Moorpark is unequalled, but Kaisha, Royal, St. Ambrose, Hemskirk, and Oullins Early are good.

Cherries were all but a failure in the open; the only sorts with a crop were Morello and Empress Eugénie. Against a north wall Hearts, Dukes, and Bigarreus were equally prolific with Morellos.

Peaches and Nectarines were a failure; even in cool houses the crop has been very thin, and in not a few instances nearly nil. Royal George is still the best Peach for every purpose, and Elruge the best Nectarine.

Nuts were a good crop, but they filled badly. Bush fruit, except Gooseberries, which varied considerably in crop in different localities, were a very heavy crop, and almost all of it rotted on the bushes. Strawberries a full crop, but the fruit smaller than usual. President was the best by far.

The outlook for another year is not very encouraging, as it is to be feared the prolonged wet will have retarded the ripening of the wood, yet there is a great show of bloom buds of every kind except Pears, which appear only scantily furnished. I shall prune hard, though from close summer pruning there is little to prune beyond sappy spray, which it is no use leaving to fall a prey to gum and canker. Notwithstanding the mildness of the season the buds are not at all forward, so that we may, if we have anything of a winter, hope that the blossoms will escape the spring frosts.

A disastrous season has not been without its effect upon the crops under glass. Peaches, as before stated, were thin in late or cool houses, and Grapes, especially late sorts, have ripened very indifferently and tardily, and I do not expect they will keep well.

Melons have done very badly; neither early, midseason, nor late crops have been at all equal to what we have had in former seasons.—A YORKSHIRE GARDENER.

THE NEW DISINFECTANT.—The purifying and antiseptic properties of the Eucalyptus have frequently been referred to, but it has been left to Mr. Knigzett to extract them and to place them at the disposal of the public in the form of the new disinfectant "Sanitas," which is composed of compounds of

the Blue Gum and Pine trees. The solution is largely manufactured at Bethnal Green.

EXHIBITION ROSES.

It may be in the recollection of some of your readers that I offered Mr. Curtis, if he succeeded in getting the twelve nurserymen named to select ninety-six exhibition Roses, to try and tabulate the same. Mr. Curtis has sent me six returns, which he is anxious should appear. These he thinks might be useful, and accordingly I now send them. He agrees with me, however, that it is not necessary to tabulate the varieties. The first forty-eight when not given here will be found in the Rose election lists in No. 867, November 8th, 1877.—JOSEPH HINTON, Warminster.

Mr. CURTIS, Torquay.

List No. 2, continued from list No. 1 (page 358) of the best forty-eight exhibition Roses.

As so many in this second list of the best exhibition Roses are of equal merit I have thought it well simply to give them in two divisions—first the best twenty-four old established varieties, and secondly the newer Roses, as under.

In making this selection due regard has been had to arrangement of colour; at least one half may be considered light Roses, and the remainder dark.

HARDY AZALEAS.

On page 449 I directed attention to the great value of these hardy shrubs for in and outdoor decoration and to their comparative scarcity in English gardens. Except a few of the older varieties of the Ghent Azaleas we seldom meet with examples of these plants either in shrubberies or conservatories. This can only arise, I think, from the newer varieties not being sufficiently known. As no opportunities are, so far as I am aware of, equal to the Belgian exhibitions held in the spring for affording a comparison of the best varieties of hardy Azaleas I will note a few which I have seen there, and which may be fairly regarded as the best yet in commerce.

Ghent Azaleas.—These are so named because they were first raised at Ghent by crossing the Turkish species of *A. pontica* with some of the hardy American Azaleas. The best varieties are quite hardy, and are very beautiful. A few of the more striking are Bijou de Gendbrugge, pure white border with rose; Louis A. Van Houtte, vermillion and orange, very bright; Sang de Gendbrugge, bright reddish crimson; Mina Van Houtte, rose, white, and salmon; Louis Hellebuyck, vermillion shaded with orange; Bouquet de Flore, rose, white, and orange; Rose de Flandre, bright rose and white; Madame Alex. Hardy, white, red, and yellow; Auguste Mechelyneck, white, rose, and yellow; Domenico Scassi, salmon rose, white, and yellow; Guelder Roos, orange and chrome yellow; and Fritz Quihow, deep bright red. I think those twelve varieties cannot be surpassed, and it is noteworthy that nine of them were raised by Van Houtte. Only the more prominent colours are given, details of the spots and stripes being omitted. A few good older varieties are the following:—Queen Victoria, Ardent-

Fig. 92.—AZALEA MOLLIS.

issima, Hilarissima, Canari, Magnificens, Gloire de Belgique, Versicolor, Bijou des Amateurs, Marie Verschaffelt, Perle du Printemps, Antoinette, and Honreuse Surprise.

Azalea mollis.—The varieties of this Japanese Azalea are striking by their large size and various-coloured flowers. The plants when in beauty appear, as I have previously said, as

being "all flowers." The varieties are necessarily limited, and the following include the very best in cultivation:—Alphonse Lavalée, orange, scarlet, and yellow; Chevalier A. de Reali, white, yellow, and orange; Dr. Leon Vignes, white and orange; Comte de Gomer, rose and orange; Isabella Van Houtte, yellow deepening to orange; M. Charles Wambecke, orange, rose, and yellow; M. Arthur de Warelles, salmon, red, and orange; Comte de Quincy, bright yellow deepening to orange; Comte Papadopoli, rose and orange; and Baron de Constante Rebecque, bright nankeen orange. All the varieties named were raised in the establishment of Van Houtte. For conservatory decoration during the early spring months no plants can produce a more imposing effect than the hardy Azaleas above named.—NOMAD.

[The accompanying engraving is a faithful representation of the improved class of flowers which have been produced by cultivation from the original species of *A. mollis*.—EDS.]

HOLME LACY.—No. 1.

THE SEAT OF SIR HENRY SCUDAMORE STANHOPE, BART.

HEREFORDSHIRE is famed for the pastoral beauty of its scenery, its verdant hills and fertile valleys, the extent of its

home but to benefit the district. How real and important are the benefits which have been conferred will be readily admitted when it is stated that the first Lord Scudamore is by many supposed to have been the first or chief introducer of the Hereford cattle, and was the first also to cultivate the Redstreak Apple and to establish the repute of its famous cider.

Before adverting more particularly to the grounds and gardens it may be well to glance at the history of this ancient place and family. So old are they that both of them are intimately connected with the Norman Conquest. Holme is evidently a modern rendering of the Saxon name *Hamme*, which signifies a house, farm, or village; or of *Homme*, a place surrounded with water. The additional name of Lacy was derived from Walter de Lacy, a valiant Norman, who acquired such great possessions soon after the Conquest that his son Roger in the reign of William Rufus had sixty-five lordships in the county of Hereford, chief of which was this one of Hamme, now Holme Lacy.

The family of Scudamore is similarly of great antiquity. It was one of those who followed William the Conqueror into England, as is evident from the roll of Battle Abbey, which contains the name of "Seint Scudamore." This family first

Fig. 93.—HOLME LACY.—SOUTH FRONT.

fruit orchards, the fine proportions of its timber trees, and the celebrated herd of cattle which bears its name. These predominating county features may be seen from one standpoint, the terrace walk of Holme Lacy, which surrounds on three sides the ancestral home of an ancient family. On the north is a sheltering belt of fine timber; on the east a rich and extensive tract of pasture land and meadows sufficiently wooded both to render it picturesque and to afford shade for the white-faced herds which drink at England's most beautiful river, the "graceful winding Wye," which meanders in bright curves through this pleasant valley; in the distance a range of bold Oak and Pine-clad hills—a noble boundary to a charming view. On the south is a park of rare beauty, thickly studded with magnificent trees, having an undergrowth of luxuriant Bracken, amongst which the fallow deer gambol; and on the west is an orchard—a real old Herefordshire orchard, also the garden. Thus the prominent features of an attractive county are embraced in the demesne of one of the oldest of county families, whose ancestors have done so much not only to beautify their

settled in Wiltshire at Upton and Norton, thence called Upton and Norton Scudamore. Walter de Scudamore was lord of the manor of the former place, and the latter was granted to Godfrey de Scudamore by Robert de Ewyas for his homage and service of finding one white horse every year for the sentinel of the Castle of Ewyas. The deed conveying this grant is still extant, and the signature of the first witness to it of Patrick, who was created Earl of Shrewsbury by the Empress Maud, and died in 1167, proves its great antiquity. Eventually the two families of Ewyas and Scudamore became united by marriage, and amongst the issue we find Sir John Scudamore of Ewyas and Holme Lacy. This place has therefore been the residence of the family from a very remote period.

Passing some eminent representatives of the family and their worthy deeds, we pause to note that Sir James Scudamore (whose father was a great benefactor to the Bodleian Library) was an esteemed friend of Sir Thomas Bodley. He was knighted for his valour at the siege of Cadiz; and it is recorded that "no

time will obliterate the brave and generous title that is given of him under the name of Sir Scudamore of Spenser's poem of the 'Faery Queen.' Sir William had two sons, John and Barnabas, both of whom have engraved their names on the history of their country. Barnabas was Governor of Hereford when it was besieged by the Scottish forces. He was twice summoned to surrender by the Earl of Leven, who received the following spirited replies:—"I am not bound to give up the King's garrison upon any summons or letters. . . . I was set in here by the King's command, and shall not quit it but by special order from His Majesty the Prince." Again: "For your favourable proffer to the inhabitants of the city I shall return their thanks and resolution that they intend to suffer with me. . . . I am sorry to think of it that two united nations should so much differ, having paid once well for Scotland's friendship. My Lord, I am resolved to endure all mines and storms which shall be made against this place, and doubt not by God's assistance to render His Majesty a good account of it." The city was not taken. John, the brother of Barnabas, was great in a different way; he is referred to above as the "first Lord Scudamore." He was created Baron of Dromore and Viscount Scudamore of Sligo by letters patent July 2, 1628. He served his country as a diplomatist, and, if I am correctly informed, was plenipotentiary at the Hague, and it was doubtless from Holland that he obtained the breed of cattle that has become so celebrated, also probably the plans for the Dutch garden at Holme Lacy, which it is very likely—though of this I have no direct information—he formed, and which now constitutes one of its prominent features. He was also Ambassador to the Court of France. He was a loyal subject of the King in troublous times, and paid the penalty of his devotion by having his house burnt and his estates sequestered during the civil wars, but subsequently regained them. After having attended as a volunteer for the relief of the French Huguenots at Rochelle he retired into private life, and then it was that he devoted himself to the planting and grafting of Apple trees, which resulted in his for the first time bringing the Redstreak cider into request, which he raised to such perfection that Phillips in his poem "Cyder," speaking of the Musk, a fine and delicate fruit, says:—

"Yet let her to the Redstreak yield, that once
Was of the sylvan kind, unvisited,
Of no reward till Scudamore's skilful hand
Improv'd her, and by courtly discipline
Taught her the savage nature to forget;
Hence called the Scudamorean plant whose wine
Whoever tastes, let him with grateful heart
Respect that ancient loyal house," &c.

Cider made of this kind of fruit was frequently given as a present to foreign princes, by whom it was highly valued. Lord Scudamore died in 1671, and it is recorded of him that "he died a rare example of piety towards God, loyalty towards his king, hospitality to his friends, economy in his family, charity to the poor, and great munificence to the church, upon which it is known he bestowed above £10,000." A noble epitaph.

In 1716 the titles became extinct, and Holme Lacy descended by a female heir to the Hon. Charles Howard, afterwards Duke of Norfolk, who died in 1815, and the Duchess in 1820, and leaving no issue the estates devolved upon Sir Edwyn Frances Stanhope, Bart., the father of the present owner, as the lineal descendant of Mary the wife of Sir Giles Bridges of Wilton Castle, Lady Brydges having been sister of John, first Viscount Scudamore. Sir Henry Scudamore Stanhope has thus not only inherited the ancient name of Scudamore, but has descended from the old family of Brydges, De Bruges, or Brughes, Earls of Carnarvon and Dukes of Chandos. I make no apology for thus gleaming a few facts relative to the history of an old family, knowing that they will be perused with pleasure, for nowhere than in Britain is honourable antiquity held in greater respect, and by none more than gardeners and horticulturists generally are the "old families" and old estates of the country more greatly esteemed.

Having referred to the family I may in the shortest possible manner glance at the mansion, and then more fully describe the externals of Holme Lacy—the park, dressed grounds, and gardens. The original mansion was supposed to have been built within the last ten years of Henry VIII., as appears by the badges of Edward VI. when Prince of Wales, which were found in the house. It was in a great part rebuilt by the second Lord Scudamore in the reign of William III., and the late owner, Sir Edwyn Stanhope, made extensive and costly alterations. Although not so large as it formerly was the

structure is extensive. It has three principal fronts. The north and east fronts are nearly 200 feet in length, and the south front 150. It is approached on the north by a terrace 700 feet long and 47 wide, and the south terrace is 800 feet in length and 30 feet wide. The arrangements internally are proportionally imposing. The entrance hall opens into a gallery 90 feet in length, lighted by stained glass windows, in which are depicted the arms of Bridges, Scudamore, and Stanhope. The principal rooms are of considerable dimensions, and communicate with each other with folding doors to the extent of 130 feet. The ceilings are extremely elaborate. The portraits—by Vandyke, Sir Peter Lely, and others—command attention, and the superb carvings of Grinling Gibbons are both extensive and exquisite—such carving that led Walpole to say, "There is no instance of a man before Gibbons who gave to wood the airy lightness of flowers, and chained together the various productions of the elements with a free disorder natural to each species." There are also real flowers and living plants in every available position, which afford evidence that the beauties of nature are cherished by Sir Henry and Lady Scudamore Stanhope, and that their garden affords to them real pleasure, as it assuredly receives their personal supervision and solicitous care.

The park at Holme Lacy merits special notice not so much for its size as for its bold rugged beauty. It afforded the standpoint for securing the view of the mansion (fig. 93), from which, as is seen, the ground slopes to the water. Beyond the water, as seen from the terrace, it again rises somewhat abruptly, forming heavily wooded slopes to an open plateau, which commands extensive views of the surrounding country, including the Black Mountains in Breconshire, the Cleve Hills in Shropshire, the Malvern Hills in Worcestershire, &c. A great portion of this park no doubt consists of the primeval forest. The giant Oaks of venerable mein and with rugged trunks suggest that they were there before even either De Lacy or Scudamore won their spurs at the battle of Hastings. How fertile is the soil of this forest-park is not more evident by the size of the timber than by the luxuriance of the Fern (Bracken), which grows 8 to 9 feet high, and covers the ground by acres, but chiefly as commanding attention are the trees. Let us look at them. That can the better be done since they are named and have their dimensions duly registered. First is the Tryeting Oak, a marvellous relic of olden times, a wonderful example of the longevity and innate vigour of the British Oak. It is not the trunk of this specimen that is imposing so much as its wide-spreading head. Its measurement was taken in 1875, when the circumference of the trunk at 3 feet from the ground was 29 feet 3 inches; at 4 feet, 27 feet 6 inches; and at the ground 34 feet. The branches extend in a horizontal manner and from 72 feet from the trunk, and cover a space of 1365 square feet, or nearly a quarter of an acre, and the tree is estimated to contain 4000 feet of timber. Another example, The Monarch, appears as healthy as a young tree. Its symmetry has been somewhat injured by the wind, yet it is a dignified and majestic tree. Its stem at 3 feet girthed 22 feet 3 inches when measured four years ago. Other equally notable specimens are the Norman, the Scudamore, the Union, the Seneschal, the Chieftain, the Warrior, the Raven's Oak, the Earl King, the Queen Mab, grotesque by its rugged corrugations; Robin Hood, representing a gigantic leaning tower; and the Weird Sisters, a Yew and Oak, so interlocked that one of them has been embraced to death by the other. Other trees than Oaks are similarly noteworthy. One of the Elms which was measured in 1869 then girthed 22 feet 3 inches at 5 feet from the ground, and reached a height of 104 feet. Larches girth upwards of 12 feet and exceed 100 feet in height, and Silver Firs have attained to nearly the same dimensions. Except the Oaks, which stand in solitary dignity and which were "born to the soil" centuries ago, the other old forest trees have been planted with considerable taste. They have been arranged in groves, and the different hues of their masses of foliage as seen from the mansion produce an excellent effect. Their trunks also as we walk amongst them, grove merging into grove—now Beeches, now Elms, now Chestnuts, now Ash, now Firs—have an attraction of their own, and impart a sylvan beauty to a singularly and variedly beautiful park. A few Yews also are of great size and have, like the Oaks, apparently been growing for centuries.

The present owner of Holme Lacy owes much to his ancestors, who have planted trees so freely yet judiciously; but he is not one of those who think the trees will live for ever, and that no duty devolves upon them to sustain and

to improve the time-honoured character of the richly wooded parks which they have inherited. No previous Lacy or Sendamore or Stanhope have discharged their duty of tree-planting and preserving more conscientiously than has Sir Henry Sendamore Stanhope of the Victorian era. Not in belts, and groups, and groves of deciduous trees only is his work represented, but the splendid Conifers—Wellingtonias, Deodars, &c.—which are interspersed with the grand old baronial trees are living memorials of the present baronet's innate love of trees, and his taste in grouping them effectively. It is sufficient to mention one of Sir Henry's tenets on tree-planting to satisfy that Holme Lacy's arboreal fame cannot be impaired while in his keeping. It is this—that every owner of property, such as parks and grounds wherein trees are a chief and natural feature, should plant hardy trees which are introduced to the commerce of this country during the term of his possession. Fortunately the home-loving, tree-loving, Nature-loving owner of this fine Herefordshire seat became impressed with that excellent idea in early life, and even before he attained his majority, now many years ago, he had permission to carry it out. Hence he sought out what trees were wanted to render the collection complete, and these he planted in well-chosen positions. The trees were chiefly Conifers, many of which are now noble specimens. Some are in conspicuous positions and planted singly, others are in groups and groves partly hidden by the larger trees and which come upon the visitor as a pleasant surprise. Indeed this is a park of surprises, of varied, bold, and romantic scenery. In one part a bold bluff surmounted with Pines commands admiration; in another a deep dell carpeted with Mosses, Ferns, and shaded by forest giants, compels a sudden pause for appreciation. Now we are in one of Nature's retreats with vegetation rampant, and from the quietude of which the deer, and the hare, and the pheasant are startled by the intrusion of man; again we emerge and are in an open plain overlooking the tops of the trees to the spires and the hills beyond. Such is the nature of this cherished park where grand old timber trees of this and thriving Conifers from other countries blend and beautify. All the trees planted by Sir Henry are duly registered; their height being entered, time of planting, and any other point of import connected with them. As an instance of their growth we note a Wellingtonia planted when about 6 inches high in 1855, and in 1875 or twenty years afterwards it was 37 feet 6 inches high, 6 feet 6 inches in girth at 3 feet from the ground, and 9 feet 9½ inches at the ground line. Cedrus Deodara, Pinus Cembra, Benthiana, excelsa, and others; also Picea Pinsapo have grown in the same satisfactory manner.

This unique park as viewed from the mansion down the glade (which is shown in the engraving) is highly imposing and singularly ornamental. This glade, it can only be said now, is a portion of the Dutch garden. The terraced avenue masked with Yews is 45 yards wide and 100 yards long. The mode of excavation that has been adopted renders the water in the valley visible from the windows of the mansion. More particular notice of the dressed grounds, topiary work, ancient and modern flower gardens, old orchards and young diagonal cordons, with a reference to an old Pear tree—a travelling tree—a marvellous and abnormal specimen which has “travelled” over an acre of ground, must be deferred.—J. WRIGHT.

VINE BORDERS.

MUCH sound advice has been lately given in these columns by “A KITCHEN GARDENER” on the above subject, but at the same time there are some statements which I cannot allow to pass unchallenged.

In the Journal for October 11th “A KITCHEN GARDENER” evidently proves to his own satisfaction that inside borders are all a mistake; but to my mind he proves something entirely different—namely, that all the inside borders which have come under his observation have been badly managed. On page 281 I read—“We will go no further than this season for a comparison between the two. Look at Vines now with their roots wholly inside and the fruit hanging on the rods. With the idea of improving the flavour of the fruit the border is kept nearly dust-dry.” By whom? I would ask. “Many of the leaves are changing colour,” he continues; “but not the colour of slow maturity; they appear as if shrivelled and scorched. Can this be otherwise than injurious to the future well-being of the Vines?” Of course not. It is the description of Vines under decidedly bad management. If I were to place a bird in a cage and allow it to dwindle from semi-

starvation it would not prove that a bird could not be kept in good condition in a cage. I need not follow “A KITCHEN GARDENER” further in this article, because all his reasoning only proves what I have endeavoured to point out repeatedly—that inside borders, as a rule, do not have a tenth part of the requisite quantity of water; but I was not aware till I read “A KITCHEN GARDENER's” article that there were in these enlightened days any quite so badly managed as are therein described.

As a proof that Vines are not always deficient in vigour when their roots are confined to the inside of the house, I may be allowed to refer to the engraving from a photograph in the Journal for December 21st last year. Not only are the roots of the Vines there shown confined to the inside of the house, but till within a fortnight ago they were restricted by means of bricks and concrete to a space of about 15 feet by 7 for each Vine, and 2 feet 9 inches deep. I cannot from actual experience positively contradict “A KITCHEN GARDENER” when he says that “Vines will succeed much better through all their existence when their roots are outside than in,” because it is not yet nine years since the eyes were inserted to raise the Vines shown in the engraving, and the range of which this is a portion contains the only instance of permanent inside Vine borders which have been under my own exclusive management; but I can assure “A KITCHEN GARDENER” that the Vines show no sign of debility at present; on the contrary, they, as well as the fruit they bear, improve every season. Four Vines (Muscats), one at each corner, now completely fill the compartment, which is 30 feet by 30.

My advice as regards the situation of Vine borders would depend on the means at command, the skill of those in charge, and the result expected. If tolerably good Grapes of the Hamburg class only were wanted from August to November with the least amount of labour, I have nothing to say against the borders being entirely outside; but if very superior fruit is required of Muscats or other Grapes which take a long season to ripen, then an inside border has many advantages, provided those in charge thoroughly understand it. Inside borders are also the best for forcing any kind of Grape. On the other hand, an unskilful man is more likely to meet with a fair amount of success if his borders are outside, because Nature will then do her best to make up all deficiencies.

I will now pass on to the Journal for November 29th, where I notice “A KITCHEN GARDENER” recommends the most extraordinary mixture for making Vine borders that I have ever heard of, and I doubt very much if either he or anybody else could grow Grapes in it. I have waited some time before noticing it, thinking possibly there might have been some printer's or other mistake which would have been corrected the first opportunity, but no correction has appeared at present to my knowledge. It reads, “The principal compost consists of moderately heavy loam with one-third decayed cow dung, the same of wood ashes, and about one bushel of smashed bones to every cartload of the whole.” Does “A KITCHEN GARDENER” seriously mean to advise equal parts of loam, cow dung, and wood ashes, or do I misunderstand him? My compost consists merely of loam with just a sprinkling of half-inch bones, perhaps about a bushel to fifteen cartloads. If the soil were likely to bind I would mix charcoal with it, which we make ourselves, and which is decidedly preferable to wood ashes.

The inside border, being completely under command, will bear to be much heavier and closer than an outside one.—WILLIAM TAYLOR.

OUR BORDER FLOWERS—POPPYWORKS.

BOCCONIA CORDATA or Tree Celandine is said to have been introduced to our gardens in 1795 from China. It is figured in the “Botanical Magazine,” and was named in memory of Paolo Boccone, M.D., a Sicilian. How a plant with such attractive properties and stately appearance has so long remained in the background I am not prepared to say. Now that plants are so much sought after for decorative purposes the Bocconia under notice is worthy of extensive cultivation. Those who are searching for hardy plants to produce effect in large open spaces in shrubberies or in borders, and as single specimens in ornamental grounds where plants of striking character are required here and there, will find in Bocconia cordata a fine acquisition. It grows freely in a mixture of good loam and sandy peat in equal quantities, a little leaf soil, and well-decayed vegetable matter. It is a strong-growing plant,

and for the full development of its handsome proportions should have room afforded it. The soil intended for its reception should be broken up to the depth of 3 feet, and the above-named compost well incorporated with the best of the soil where it is intended to grow. It should have thorough drainage, being a gross feeder; when required it should be supplied with water, all the better for having weak liquid manure water now and again; it is increased by division in the spring when growth is commencing.—*VERITAS*.

MARKET APPLES.

MR. ROBSON in his welcome remarks on page 450 has directed attention to a failing point in the popular Apple Cellini. It is too tender, Mr. Robson has said, to travel a long distance well, and the fruit does not turn out of the baskets in good condition. From the fact that Cellini is an Apple of good appearance and quality, also that the tree has proved a good bearer even during the past barren season, it is probable that trees of it may be rather freely planted. It becomes, therefore, the more important to give prominence to any bad qualities that it may possess, that they may either be disproved or substantiated. I have grown this Apple with satisfaction to myself and employers, but have not had experience in marketing its fruit; but I have had the advantage of listening to a cultivator whose opinions always commanded respect—the late Mr. J. R. Pearson of Chilwell, whose views coincided with those of Mr. Robson on the bad travelling properties of the Apple in question. I have heard Mr. Pearson remark that Cellini was an excellent Apple for home use, but it would never be popular as a market Apple. Twelve hours in a basket and a hundred-miles journey on a railway was in his opinion quite sufficient to spoil the appearance of the fruit. This is a matter of such importance to so many cultivators that I think it unadvisable that the experience of one—for no doubt Mr. Pearson spoke from experience—should remain unpublished. Those who have had much practice in the gathering and storing of Apples cannot but have observed how the bruises received by one kind will spread and show, while those of another remain almost imperceptible, and, indeed, apparently diminish.

The Apple which Mr. Pearson considered one of the most valuable for early market purposes is the Duchess of Oldenburgh, an early free-bearing variety of Russian origin. I have heard that gentleman state that no Apple of its season would travel from Nottingham to Manchester so well as the Russian. None other, he remarked, could "hide its bruises" so well; in fact he observed that it improved in appearance after having been removed from the baskets, the bruises apparently vanishing, while those of Cellini always increased. The Duchess of Oldenburgh is a handsome Apple—good in size, colour and quality; and as it ripens early (August), and the tree is a healthy grower and great bearer it is worthy of the attention of cultivators. It forms an attractive bush or pyramid, and is suitable for small gardens.

A popular market Apple in some districts of the north of England is a small very richly coloured sort called Lord Lennox. It is a dessert fruit, but not of particularly high quality, yet is fairly good. It is chiefly on account of its round pleasing form and bright scarlet colour that it is esteemed as a market fruit. The tree is a very clean and free grower, and it forms, when unpruned, natural spurs, and produces heavy crops of fruit. It roots more freely than most other sorts, and seems to thrive in almost any sort of soil. I have seen it growing almost in a swamp; indeed quite so during the winter months, and have never yet observed a speck of canker on either root or branch. It has never occurred to me before this moment that Lord Lennox would probably form an excellent stock for the Ribston Pippin, which is yet the favourite market Apple for dessert purposes, but seldom seen on account of the proneness of the tree to canker. Will someone having an opportunity of doing so graft the Ribston Pippin on the Lord Lennox stock, and in due time report progress? A few years ago I was compelled to plant twelve Apple trees in as many sorts in a very low wet soil, and Lord Lennox is the only one that is entirely free from canker. It makes a fine standard tree, and its fruit does not readily blow off during a brisk wind. It is probably a local Apple, and I know nothing of its origin or history.

Two other local Apples of undoubted usefulness, especially as orchard standards, have been favourably mentioned in the *Journal*—namely, the Russian Transparent and Bramley's

Seedling. I have not yet grown these Apples to a bearing state, but I have seen them growing and fruiting. They are both of them fine and profitable Apples that anyone can grow who has room for full-sized standards. They only require to be planted, and they will grow and form natural spurs and bear large fruit of excellent quality for culinary purposes. They are both of them "market Apples" which, when once in a bearing state, will pay producers and satisfy consumers as well as any Apples of their kind and season that I am acquainted with.

Beauty of Kent is a good "market Apple," but by no means a local sort. It is mentioned now by way of knocking away a prop, if possible, that supports a popular delusion. This Apple is supposed to be suitable for the southern districts of England only. I have seen it flourish in the north and produce good crops when many other sorts had succumbed to the inclemency of the weather. So far from its being a tender sort I consider it as hardy as Dumelow's Seedling, or, as it is called in the north, Normanton Wonder. Beauty of Kent, besides being hardy, is a free bearer; its fruit is large, of good colour, and of superior culinary quality.

Normanton Wonder is a favourite "market Apple" in the north, not because of its high quality, but because of its firmness in late spring. As a "May-day" Apple it is perhaps the first favourite in many districts. The tree generally bears heavily, and the fruit usually commands a good price.

Another Apple of great promise as a market sort is the Worcester Pearmain. The tree is a good grower and bearer, and the fruit is extremely handsome and highly coloured—almost blood red, and of the first quality. It can hardly fail to become very popular, possessing as it does such a combination of attractions—namely, easy to grow, fine to look at, and excellent to eat.

Warner's King is a very favourite market Apple. The tree is a good grower and bearer; the fruit is of large size, of good appearance, and of excellent quality. "King" Apples, as they are often called, are extremely popular in the north.

I have only mentioned a few useful market Apples which I think are not quite so well known as they deserve to be. There may be others equally good, and which are passed over because their usefulness is admitted. I will only allude to one that Mr. Robson has made to look "rather small"—Lord Suffield; and of this I will only say that if returns could be had of the number of different sorts that are annually grafted and sold, I believe Lord Suffield would be found to far outnumber any other Apple grown in Britain.

I think with Mr. Robson that the Apple is at least as important as the Rose; but admirers of Apples are not so enthusiastic or possess such facile pens as do lovers of Roses, or the relative merits of varieties of the most serviceable of hardy fruits would be more freely discussed.

The crops in the north have been scant this year, and much fruit that set did not attain to more than half the usual size: it was also so malformed by injury from hail and severe weather as to be in a great measure unrepresentable at exhibitions.—A NORTHERN GARDENER.

NOTES AND GLEANINGS.

WE are glad to learn that the amount in the funds at the credit of the GARDENERS' ROYAL BENEVOLENT FUND is now £11,300, the additional sum of £300 having been recently purchased. In consequence of the death of two pensioners having occurred since the election lists were issued two more will be added on the recommendation of the general meeting.

THE dates for the exhibitions of the NATIONAL ROSE SOCIETY for 1878 are now fixed. The metropolitan Show will be held at the Crystal Palace on Saturday, June 29th, and the provincial Show at Manchester on Saturday, July 6th, in connection with the Manchester Botanical Society. In both instances the Hon. Secretaries regard the arrangements as very advantageous to the interests of the Society; they have endeavoured to get some other day in the week, but were obliged to give way. The Executive Committee will meet early next month to arrange the schedules in order to submit them to a general meeting of the Committee.

THE HORTICULTURAL CLUB, which has been located hitherto on the Adelphi Terrace, are about to migrate to the Temple Club in Arundel Street. There can be no doubt as to the change being for the better, and consequently in the interests of the Club, which have certainly suffered from its

connection with its former habitation. Great complaints were made by members of the Club with the arrangements that were made for their accommodation, and this was the cause of many resignations. We hope now that these inconveniences are at an end we shall see the return of the old, and a large accession of new, members.

— Mr. JOHN WARDLE, gardener, Newton Hall, informs us that his relative, Mr. William Wardle, who was formerly an amateur gardener at Newcastle, was the raiser of ALLAMANDA WARDLEANA. It is one of the finest of the Allamandas, flowers having been produced at Newton Hall 8 inches in diameter: the plants flower freely in quite a small state and are very valuable for decorative purposes.

— We have received from Mr. George Duffield of Brampton Lodge a FASCATED STEM of DUCHESSE DE MORNAY ROSE. The stem was quite flat, about three-sixteenths of an inch in thickness, and was nearly 2 inches wide. The summit was covered with foliage, and almost resembled a fan. We never saw a more striking instance of Rose fasciation. The exuberant growth suggests that the soil at Brampton is very rich and suitable for Rose cultivation.

— I do not understand, writes an experienced gardener to us, after thirty years of practice, the DEFINITION of a CAULIFLOWER or BROCCOLI. Which is which? My ideas were that a Cauliflower referred to such as if sown in spring would head the same summer or autumn, and a Broccoli if sown in spring would not "flower" the same season. Will some of your correspondents tell me how to know a Cauliflower from a Broccoli (not Cape)? If Snow's Winter and Veitch's Autumn Broccoli are only distinguishable from Cauliflowers by "flowering" later, why designate them as Broccoli? Walcheren Cauliflower is also Walcheren Broccoli, but it is as much a Cauliflower as Early London, Asiatic, Stadtholder, Autumn Giant, and others boasting the name of Cauliflower. Either some Broccoli are Cauliflowers or all Cauliflowers are Broccoli.

— We have received the schedule of the PELARGONIUM SOCIETY'S SHOW which is to be held next year at South Kensington on June 18th. Every section of the Zonal Pelargonium is provided for, and liberal prizes are offered in thirty-three classes. In order to meet the increased expenditure incident to the expansion of the operations of the Society, members are invited to exert their influence in obtaining an augmentation of the subscription list. We are pleased to observe that the finances of the Society are in a healthy state, and that a balance in the hands of the Treasurer of £42 6s. 8d. is recorded. The Zonal Pelargonium is so popular and useful, is in fact an "everybody's flower," that the Society which is established to promote its improvement is highly worthy of support. Since many of the varieties are proving so valuable for winter decoration it is worthy of consideration as to whether prizes should not be offered to be competed for during the winter months, say at the December and January meetings of the Royal Horticultural Society. Healthy and well-bloomed plants are fully more valuable in winter than in summer, and their successful cultivation during the "dark days" is worthy of the encouragement of this patron Society. Mr. Cannell has shown what splendid flowers some of the varieties produce in winter; but we should like to see plants as well as cut blooms exhibited.

— It is with much regret that we have to record the outbreak of a calamitous fire which occurred on the morning of the 23rd inst. at the works of the eminent horticultural builders, Messrs. John Weeks & Co. of Chelsea. The branch establishment destroyed is the one adjoining Mr. Bull's nursery, which also, we regret to hear, sustained injury, one of the houses being burnt, but most of the plants were fortunately preserved. Notwithstanding the efforts of the firemen, engines, and hydrants, Messrs. Weeks's large building and much valuable machinery were totally destroyed. The origin of the fire is unknown; and the loss amounts to £10,000, of which about £2500 is covered by insurance. A firm so extensive as the Messrs. Weeks do not, however, "put all their eggs in one basket;" they have yet three other establishments for carrying on their business, which we are authorised to announce will be conducted in the usual way. They have received much kindness and sympathy from their neighbours, several engineers and builders having placed their plant, &c., at the disposal of the firm.

— We have received a selection of those useful annuals LETT'S DIARIES. They are in various sizes, from the small

miniature for the vest pocket to a considerable-sized scrap book. They are conveniently arranged, and contain much useful information on a variety of topics. We have experienced the value of these familiar diaries, almanacs, and pocket books during previous years, and can recommend them as being as good as ever—excellent of their kind.

— It is gratifying to know that living plants of the remarkable WELWITSCHIA MIRABILIS are now in the Kew Botanic Garden, several attempts to introduce this curious plant in a living state having failed. Even imported seeds have failed to germinate.

— A VISITOR to Mr. Bass's fine GARDEN at RANGEMORE informs us that extensive alterations are being conducted by Mr. Bennett. An additional twelve acres are being taken in to the pleasure ground. The lake is being enlarged, and much levelling and planting is being done. The mild weather is an immense advantage to the prosecution of the alterations.

— OUR correspondent, "A KITCHEN GARDENER," writes to us as follows on the value of the ARBUTUS:—"At this time of year when there is such a demand for berried evergreens it may interest some of your readers to know that the Arbutus far excels every other shrub for the beauty of its fruitful sprays. We have over a dozen trees of it, some of them between 20 and 30 feet high, with clusters of ripe Strawberry-like fruit hanging from every branch. The fruit is just about the size, shape, and colour of ripe Black Prince Strawberries. The shrub grows freely amongst other evergreens, and although it is generally considered to succeed best near the sea, it is well worth trying in inland gardens." We may remark that this beautiful evergreen flourishes well in the southern counties of England, but we doubt if it is sufficiently hardy for exposed gardens in northern districts. What does Mr. Abbey say of its endurance in Yorkshire?

— THE great desideratum in fruit is something very late or early; it is not always that one sort possesses both properties. Having been induced to try SUTTON'S ROYAL HORTICULTURAL PRIZE MELON we cut the earliest on the 1st of May and sent in the last on Christmas day, my employer saying the last was as good-flavoured as the first; it is also a good setter and free grower.—EROMEGNAR.

— RESPECTING the WEATHER IN SOUTH WALES, a reader of the Journal there writes:—"The weather here is very mild and humid. Since the middle of October it has rained half the time. Previous to that we had capital weather, and fruit-tree wood is fairly well ripened. We have had a cold night or two, but a few Potatoes growing on a south border are as green in the haulm as in June. Young Cauliflowers and Lettuces for the earliest crops in spring are strong and healthy out in the open border. They have never had any protection. Violets are abundant in the open air. Primroses may be gathered in handfuls. Last year we could hardly find a single Holly berry: this year every tree both green and variegated is literally loaded with them. Last year at Christmas we had armfuls of Laurustinus flowers: this year we have not handfuls. A sharp frost would do much good, but we do not have much of that here; and as for snow, we have very rarely the pleasure of seeing it."

— MM. LECHARTIER and BELLAMY give an account in the *Comptes Rendus*, lxxxiv., 1035, of some experiments they made on the FERMENTATION OF APPLES when enclosed in vapours such as carbolic acid, camphor, and potassium cyanide. From their results it appears that no fermenting action took place in the Apples surrounded by vapour of carbolic or hydrocyanic acids, and a slight action only in the one surrounded by camphor vapour. The camphor vapour, in fact, diminishes without entirely destroying the vitality of the cells. In this journal, also, there is an account of experiments performed in the same direction by M. Gayon. He enclosed the Apples in vapours of chloroform, ether, and carbon disulphide, and his results agree with those of the first observers. The chloroform and ether act in the same manner as the carbolic and hydrocyanic acids; the carbon disulphide in the same way as camphor, permitting partial fermentation only.—(Nature.)

— A WELSH correspondent sends us the following extract from the ancient laws of Wales to show the value of Yew in long bygone days, especially when it had been consecrated by the priests: it then exceeded in price the sacred Mistletoe of the Druids:—"A consecrated Yew, its value is a pound; not consecrated, fifteen pence. A Mistletoe branch, threescore pence. An Oak, sixscore pence. A sweet Apple, threescore

pence; a sour Apple, thirty pence. A Thorn tree, seven pence halfpenny. Every tree after that, four pence."

— THE weight, says an American writer, affords the easiest test for the PURITY OF GUANO. A bushel of pure Peruvian guano, according to most authorities, should weigh almost exactly 70 lbs. If heavier than 73 lbs. it is adulterated with clay, sand, marl, or some other impurity.

— THE *Prairie Farmer* states that \$2,500,000 worth of American dried fruits have been sold in Europe during the last twelve months; also that Ohio has 381,000 acres of Apple orchards, and raised this year 15,000,000 bushels of Apples.

— SOME few months ago, says the *Mercantile Gazette*, a pathetic lamentation went the round of the press, emanating from M. Piesse, in consequence of the Russo-Turkish war interfering seriously with the manufacture of ATTAR OF ROSES. The last number of the *Indian Agriculturist* thus comments upon it:—"M. Piesse, of the firm of Piesse & Lubin, the celebrated perfumers, writes quite romantically to the *London Times*, 'Come, then, Western Australia! come, then, Queensland! come, then, Fiji! all the Roses you can grow will be a welcome to British commerce. This article is worth alone £80,000 sterling per annum.' M. Piesse had evidently no idea of the Neilgherries and the Roses that grow upon them. Ootacamund and Coonor should be in a position to supply M. Piesse with a very large quantity of the article he needs. The manufacture of attar of Roses is simple enough, and no difficulty will be experienced by those who are inclined to try it to get the necessary information. This source of industry may prove the means of relieving many who are now suffering from poverty on these hills."

— "EROMEGNAR" sends us the following note of his experience on the question of LOAM *versus* PEAT FOR RHODODENDRONS:—"In making some alterations we had to remove a bed of large Rhododendrons. The bed had been excavated 3 feet deep, one half having been filled with peat, the other loam. There was no comparison in their rooting. Those in loam had balls as large as the body of a cart; in the peat, on the contrary, they were not a quarter the size, and you could tell to a plant how far each kind of soil extended before the shrubs were taken up."

NOTES ON VILLA AND SUBURBAN GARDENING.

ALL work that has been advised in previous calendars and not yet completed must be finished without further delay, for with the ushering-in of the new year garden work and garden cares commence afresh. In a very few weeks many operations will be found pressing to be done at one time, consequently all work that it is possible to do to facilitate work in the spring should be done at once. The wheeling of manure, the trenching of ground and laying it in ridges for the frost to act upon it, the pruning of all kinds of fruit trees, the sweeping and rolling of lawns, and the turning of the borders under shrubs, all constitute work for the present time. Adapt the work, too, to the weather, and both master and man will be benefited. For instance, manure is best wheeled during frosty weather, for then the paths are hard and firm. Trenching is brisk warm work for cold dry days, and warm pleasant days are the most profitable for pruning. After rain the roller will make the greatest impression on lawns, and is highly beneficial if an even and thick sward is wished for. It is surprising how great are the advantages of adapting the work to the weather—working with the head as well as with the hands.

Peaches and Nectarines on walls should be all unnailed and the branches be secured to stakes some distance from the walls, in order to retard the buds as much as is possible, for the longer the expansion of the blossom can be retarded the greater is the chance of favourable weather during the setting period, and of a good crop of fruit resulting.

Apple and Pear trees, whether grown as bush or pyramid trees or in the form of espaliers by the side of walks, &c., should be carefully pruned and trained now. A judicious thinning of the small weak wood is necessary, keeping the centre of the tree, in the case of standards, open, so as to admit a free current of air through the trees. The pruning of all small fruits, such as Gooseberries, Currants, and Raspberries, must not be delayed after this time. Gooseberries and White and Red Currants should have their centres kept open by pruning all side shoots nearly close to the main branches, removing also the points of the principal or permanent portions of the bushes; but Black Currants merely require an old shoot or so to be removed to prevent overcrowding. Raspberries require to have the points of the canes shortened, removing also the weakest of the superfluous canes. Some cultivators secure the canes to stakes,

others have a wire trellis to which they tie them out separately, while some train them by what is known as the arch system—that is, the points of the rods from one stool are secured to the points of another, and by this means the growth is well exposed to the light. All the modes of training alluded to answer well, and that one may be adopted which is the most convenient. Gather up all prunings, and those of the Apple and Pear may be tied in bundles and be reserved for small flower sticks, while the prunings of Gooseberries and such like should be burnt, when not required to be made into cuttings.

Shrubberies and pleasure grounds are now attractive where Holly abounds. So numerous are Holly berries on some trees this season that they almost make the foliage look dull and sickly by contrast. *Jasminum nudiflorum* just now clothes the walls of many a villa home with its clear yellow flowers, while the *Arbutus* and *Laurustinus* are heavily laden with clusters of white and graceful blooms, and *Garrya elliptica* is profuse with its bold and drooping catkins. All of the shrubs impart a charm to an otherwise dull and dark month, and make us feel that, after all, there is always something to admire in a well-furnished garden be it ever so small.

Vines in houses where there is not much artificial heat have nearly shed their foliage. They are now ready for pruning, dressing, and cleaning. The system of pruning most common as yet is the spur system, according to which the laterals are pruned back to within about two eyes of the main rod. Employ a sharp knife for the work, and do not cut too close to the bud. Wash the rods with soft soap and tobacco water, and they may also be painted over with a mixture of sulphur, tobacco water, and clay, as thrips and other insects may be lurking within the crevices of the bark. All inside borders will require a good soaking of water, for though the tops are apparently dormant the rootlets are active. It is well to remember that the finest Grapes as a rule are grown where the rainfall is the heaviest.

Bedding Geraniums require to be frequently looked over and to have all decaying leaves removed. They must be watered moderately, for nothing is gained by allowing them to become dust-dry, more especially if a little fire heat is used. *Cinerarias* and *Calceolarias* are growing well, and are as a rule strong and healthy. They should be kept near the glass and liberally supplied with water on fine mornings. Continue to bring in fresh batches of bulbs, *Spiræas*, *Deutzias*, *Azaleas*, *Rhododendrons*, *Lilacs*, *Dielytras*, *Roses*, &c., for forcing as wanted, and other *Roses* in pots will require pruning for later supplies. Before pruning see that the soil has become tolerably dry, then with a sharp knife cut away all weak shoots. Place a strand of cord round the rim of the pot, and bring gradually down sufficient shoots to lay the foundation for a compact plant. The shoots so tied down make more breaks than they otherwise would do if left erect, and consequently will give a greater supply of flowers. Do not attempt too high a temperature for forcing the *Rose*; from 50° to 55° is ample. Syringe frequently, and as growth commences give more water. It is a very good plan to prune some weeks previous to starting the plants into active growth.

Leaves that have been collected and laid in a heap should be mixed with some long and fresh stable manure for the purpose of forming a hotbed for the raising of early frame Cucumbers, the striking of numerous cuttings, and the raising of seeds during the spring months. Directions for the making of the beds will be given in due time; for the present allow the materials to ferment and sweeten.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

HARDY FRUIT GARDEN.

WE have already given the various details of the work on the open ground and on walls. There are, however, exceptional conditions that must be taken into account, such as undertaking the charge of a garden where the trees have for years been neglected. It was our own experience to do this once, and we found weeks of employment in thinning-out the wood where it was too thick, taking care at the same time to leave a sufficient number of fruit buds for a crop the following season. In pruning standard trees the right principle is to thin-out the outer branches liberally, so that the sunlight may play freely on the fruit about the centre of the trees. Old and neglected trees will have very few fruit buds near the centre; they will nearly all be found on the outer branches. When standard trees are well managed from the first the inner branches will be furnished with fruit buds, not to the same extent as those on the outer side, but they will be evenly distributed over the trees, and the branches will not be so liable to break with their load of fruit in seasons of plenty. Neglected wall trees, especially Pears and Apples trained on the espalier system, are most unsightly objects. We have seen them with the spurs projecting nearly half a yard from the main stems. The best thing to do when this is the case is to cut the spurs back rather closely. Such treatment may have the effect of very materially diminishing

the chances of a crop of fruit the following season; but the trees will be made slightly, and by good management they can very speedily be brought into a bearing condition.

It is not wise to train the horizontal growths too near each other; 9 inches apart is a good distance, and when the walls are of brick it is easy to train the growths along the seams. When the wall is quite furnished the only attention required for such trees is to keep the spurs close to the main branches. Fan-trained trees are rather more difficult to keep in order as the trees get old. The fruitful portions are to be found more and more at the outer verge of the branches, and when the old trunks become almost destitute of buds it is best to cut them quite back and to train up young wood that will ultimately bear freely.

Those who are furnishing new walls with trees will have done well if they followed our instructions and selected their trees in the nursery early in the season. If well-trained four-year-old trees are planted they will come into bearing the second year after planting. It is the practice with many gardeners to cut back the young growths of last year very severely. If the trees are healthy and well furnished with roots this is not a wise plan. The young wood should be cut back to two-thirds of its length only, and the branches must not be nailed to the walls until the ground where the trees are planted has subsided. Peaches and Nectarines are usually the last to be nailed. If the young wood has been attacked by aphid or scale it should be well washed with strong soapy water. All planting should be finished as speedily as possible. Gooseberry, Currant, and Raspberry bushes should be planted, and the ground mulched to keep frost from the roots. If the canes and bushes are planted in an exposed situation it is well to place a stout stick to them to keep them steady in high gales of wind.

PINE HOUSES.

The time is now drawing nigh when the succession plants must be started. About the first week in January we move all the plants out of the tan bed, where the roots have been dry, and in a temperature of not more than 75° or 80°. We either use fresh tan entirely or sift the old stuff to separate the dust from the rougher portion. After mixing the rough portion that is left with any that has been obtained fresh from the tan pits level it down and then plunge the pots to half their depth, if deeper excessive heat may injure the roots. In six weeks or more the heat and tan subside together. A portion of fresh tan may be added to the surface, which will increase the heat again. The plants ought not to want for water after they are started, and the temperature of the house, which ranged from 55° to 60°, should not fall below 65°. The house should be damped twice a-day, and the surface of the beds may be occasionally syringed. In the houses where fruit is approaching the ripening stage, and others having fruit in various stages of development, the atmosphere must also be rather moist, and as yet much care must be exercised as to watering; if the compost becomes too dry the stem of the fruit shrivels, which causes premature ripeness and deficiency of flavour. If too much water is applied there is a probability of the fruit becoming black at the core. This mischief is also caused by giving too much manure water. We always apply manure water with caution to Pines, and especially so in the winter. The house where the young suckers are kept will not have more heat than 55° or 60° until the first week in February, when the temperature may be advanced to 65° as a minimum. After keeping up this temperature until the middle or third week in February the Pines may be potted.

GREENHOUSE AND CONSERVATORY.

We have been tying out and placing sticks to plants of various kinds, and it is well to push forward all work of this kind when time can be spared for it. Stage Pelargoniums that were potted a few weeks ago have now taken hold of the fresh compost and are making sturdy growths; the plants are not large, else it would have been necessary to place a stout wire round the pots at the outer limit of the branches; this can easily be done by placing sticks across the rims of the pots and making them fast. In our case it was only necessary to fasten a piece of rope yarn under the rim and to tie down the shoots to this, thinning them out where they were crowded. Some care is necessary in bending them down not to pull the shoots too much, else they are likely to snap off. We just give sufficient water to keep the soil moist and not to allow it to become too dry. If too dry the older leaves are likely to become yellow and must be picked off, and too much moisture causes spot. Fumigate to destroy green fly. Cinerarias are growing vigorously, and must be kept in a house close to the glass; air must be admitted freely, but the plants are much injured if they are placed in a draughty place. A dry atmosphere is not suitable for them. Give weak liquid manure water occasionally if the pots are filled with roots. That made from cow manure is the most suitable. Coronilla glauca and Cytisus racemosus are valuable for producing flowers now and onwards until other flowering plants are more plentiful. The bright yellow flowers are very striking, and the plants are very easily grown. Heaths and Epacris that flower at this season must be taken care of. The withered and mouldy

flowers must be removed, as they have a tendency to produce decay.

The first batch of Hyacinths, Tulips, and Polyanthus Narcissus have been placed in gentle heat, and they are growing freely. Other spring-flowering plants, such as Deutzias, Spiræa japonica, and other hardy-flowering shrubs may be placed in heat, also a few Roses; a very gentle bottom heat with a temperature of 55° will cause the plants to grow freely. But we find that the growths are weak and flowers are not freely produced unless the plants are kept rather close to the glass. It is not wise so early in the season as this to place plants in the house to force, that have not been properly prepared. They are prepared by being established in the pots some time before they are forced, so that when they are excited to grow the roots are ready to supply sap.

By judicious management and very little expense a few Tea Roses may be in flower now. The plants should be placed in an airy house with a night temperature of about 55°, and air should be admitted as freely as may be deemed desirable. The outer petals are apt to become mouldy if the temperature is not high enough and the air about the plants is stagnant. Some of the Tees are bad openers, and some are not so useful for cutting as others. Niphetos and Safrano are the two most employed by the bouquetists in Covent Garden. Beautiful buds of those two may now be seen in the windows with sprays of Euphorbia jacquiniiflora, the small Roman Hyacinths, and other neat little flowers; indeed, many of the small button-hole-bouquets are rather overdone with these small flowers. A neat fresh Rose bud with its own bright glossy green leaves would be more esteemed by a person of taste.

FLORIST FLOWERS.

Little can be said about these at this time, except that Auriculas require to be looked over to remove all the decaying leaves, and to scratch over the surface of the pots if moss is growing. Whether or not, it does good just to scratch the surface each time the plants are picked over. There are few frames where drip is not to be found, and we have had valuable specimens quite sodden at midwinter through being placed under the place where water has dripped into the pot in wet weather. Carnations and Picotees also require looking over in the same manner. We have not thought it necessary to protect the Tulip beds from wet; there seems no reason to do this in our district. In wet heavy soils the growers have iron hoops bent over the beds, and some sort of canvas is hung over them to throw off the rains and protect the plants coming through the ground from frosts.—J. DOUGLAS.

TRADE CATALOGUES RECEIVED.

Sutton & Sons, Reading.—*Amateurs' Guide in Horticulture, and General Catalogue of Vegetable and Flower Seeds, Potatoes, &c. (highly illustrated).*

James Carter & Co., High Holborn, London.—*Vade Mecum and General Catalogue of Vegetable and Flower Seeds, Potatoes, &c. (highly illustrated).*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

BOOKS (*Fantail*).—Leighton's "Lichen Flora," and Berkeley's "British Mosses." (*A Constant Reader*).—The two dictionaries are one and the same. (*Cuskin*).—"Outdoor Gardening" and "Indoor Gardening." You can have them by post if you enclose 3s. 6d. in postage stamps.

BEGONIA (*C. F.*).—We cannot name florists' varieties, they are too numerous and nearly alike.

VINES FOR COOL HOUSE (*R. A. P.*).—Black: Black Champion, Black Hamburg, Mill Hill Hamburg, and Black Frontignan. White: Buckland Sweetwater, Foster's Seedling, Dr. Hogg, Royal Muscadine. We did not receive your former letter. Many letters have recently been wrongly delivered, and it is only by the courtesy of our neighbours that we have received important communications which have been addressed to us. Replies to correspondents are usually given in about a week after the questions are received.

VIOLETS (*E. L. P.*).—The correspondent you name is not a dealer.

GRUB (*A. Wilson*).—It was entirely smashed. Probably it is the grub of the Diddy-longlegs.

HEAT IN VINERY AT REST (*Amateur*).—You may keep the house as a warm greenhouse. Do not let the temperature fall below 45° or rise over 50° during the winter. Begonias and many species of Ferns would be safe in such a house. Roses will be quite safe in a cold frame until spring.

CROPPING VINES (*Idem*).—Old Vines that have been forced and heavily cropped for twenty years will be well nigh exhausted. As the roots have gone down 8 feet below the surface you might try what effect raising them nearer the surface would have. They will never succeed so well as young Vines.

DOUBLE PRIMULAS (*Idem*).—If you intend to grow double Primulas for exhibition it will be necessary for you to obtain all the varieties that you

can. You must grow them near the glass in a cool house or glass frame facing north. Good yellow loam, with a little decayed manure, leaf soil, and lime rubbish, is the best compost for them. The size of the plants must be an index to the size of the pots. Exhibition plants ought to be large enough to be exhibited in 8-inch pots.

ROSES FOR FORCING (*Sir Ashley*).—The first lot to be started in January from your list should be Anna Alexieff, Madame Victor Verdier, John Hopper, Paul Neyron, Dupuy-Jamain, Jules Margottin, Victor Verdier, Dr. Andry, Midle, Marie Bady, Comtesse d'Oxford, and La France. For the second lot take Henry Bennett, Madame Lacharme, Baron Haussman, Abel Carrière, Camille Bernardin, Thomas Mille, François Courtin, François Michelon, La Rosière, Duc de Rohan, and Maurice Bernardin. For the last lot Duchesse de Caylus, Pierre Notting, Duke of Wellington, Alfred Colomb, Capitaine Christy, Sir Garnet Wolseley, President Hardy, Thyra Hammerick, Lord Macanav, Jean Cherpin, Madame Thérèse Levet, Fisher Holmes, Sir J. Paxton, Duc de Montpensier, and Etienne Levet.

WINTERING TUBEROUS-ROOTED BEGONIAS (*M. A.*).—They rest in the winter, and should not be excited by being placed in heat. Keep them in a dry cool greenhouse or cold frame.

CULTURE OF ORCHID (*Donna Serafina*).—We do not know Dendrobium Harrisonii. Have you not made a mistake in the name? Send us a leaf and that may assist us.

NAME OF SEED (*M. D. D.*).—The seed is from a species of Momordica, and it is probably *M. Charantia*. It answers well to the description you give; and, further than your letter describes, the seeds are immersed in scarlet pulp. The bursting of the fruit, especially to expose a brilliant interior, is unusual in the family of Cucurbita. It requires to be sown in bottom heat about the middle of March, and, like all of the Cucurbit relationship, must have an unchecked growth onwards to maturity. A little later sowing should be made if there is any danger of check. Rough loam enriched with a little manure forms the best compost. Place two plants well down to the seed leaves in a small 60-pot and plunge in bottom heat, thence when required shift into a 32-sized pot, then into a 24, and at last into as large a pot as convenient. Let there be good sticks for the support of the stems from the first, for they never properly recover the bruising of a disentanglement. A warmer temperature than of a greenhouse is requisite, though stove temperature is rather too high. A greenhouse may be kept close to suit its requirements.

NAMES OF FRUITS (*Somerset*).—The numbers were all shaken from the Apples when they arrived, the strings having slipped off. The best way is to stick the numbers on with pins or wrap each specimen in a separate piece of paper on which the number is written.

NAMES OF PLANTS (*W. W. A.*).—1, *Asplenium marinum*; 6, *Pteris serrulata*; 8 and 4, forms of *P. cretica*; 7, *Selaginella uncinata*; *Polypodium Phymatodes*; *Pellaea foliata*. (*J. T. H.*).—1, *Cheilanthes myriophylla*; 6, *Pellaea quadrifida* var. *argyrea*; 7, *Adiantum formosum*.

POULTRY, BEE, AND PIGEON CHRONICLE.

NORTHALLERTON SHOW OF POULTRY, &c.

The first winter Show took place at Northallerton on the 19th and 20th inst. The entries were unusually large, there being about 830 pens. The birds, &c., were spread over six rooms, and no show, owing to the absence of light, was more difficult to judge. In the large varieties of poultry a pen of splendid Buff Cochins won the cup, and for Hamburgs, Game, and Bantams a pen of Piles won. The Selling classes were very good, the entries large and many birds claimed. Pigeons were still worse placed for light and inequality as to position, some being not less than 8 feet high, while others were near the floor. They were very good; the Dragons contained no less than forty entries.

Cage Birds were neatly arranged in a small room and were a very pretty display, the Norwich Canaries being specially good and well shown. Lizards were all noticed, and Silvers won the prizes. In British Birds a capital Goldfinch was first, and Thrushes second and third.

Rabbits and Cats were also well exhibited.

CAGE BIRDS.—NORWICH CANARIES.—Yellow-marked or Clear.—1 and 2, H. Stebbings. 3, Stevens & Tennisswood. Buff.—1 and 2, J. Cleminson. 3, C. Burton. Evenly marked.—1, J. Cleminson. 2, C. Burton. 3, C. Greenwood. YORKSHIRE CANARIES.—1, R. Atkinson. 2, Stevens & Tennisswood. 3, T. Hutchinson. LIZARD CANARIES.—1, J. Cleminson. 2, W. Addison. 3, Stevens

and Tennisswood. CANARIES, ANY OTHER VARIETY.—1, T. Cleminson. 2, Stevens and Tennisswood. 3, J. Cleminson. MULE.—1 and 2, Stevens & Tennisswood. 3, Bell & sister. GOLDFINCH OR LINNET.—1, T. Cleminson. 2, T. Green. 3, T. Hutchinson. ANY OTHER BRITISH BIRD.—1, W. Burniston. 2, T. Mayne. 3, W. Archer. PARROT OR PARROCKET.—1, R. Pearson. 2, Mrs. G. Oliver. 3, R. Mais. ANY OTHER VARIETY.—1 and 2, W. Burniston. 3, J. Ward.

RABBITS.—LOP-EARED.—Buck or Doe.—1, G. F. Clarkson. 2, G. S. Nellist. ANY OTHER VARIETY.—Buck or Doe.—1, Misses Walker. 2, Miss Hailstone. 3, J. Hawkwel.

TORTOISES.—TORTOISESHELL AND WHITE.—1, E. Horner. 2, C. Graves. BROWN OR RED TABBY.—1, W. Jenkins. 2, E. Horner. BLACK OR WHITE.—1, W. Bailey. 2, W. Atfield. 3, S. A. Pocock. ANY OTHER VARIETY.—1, Rev. E. A. B. Pitman. 2, Mrs. R. Chapman.

LOCAL CLASSES.—TURKEYS.—Poults.—1, Mrs. Heslington. 2, Miss Booth. 3, F. Woodhouse. GOSSINGS.—1, T. P. Walker. 2, Miss Booth. 3, J. Collins. DUCKINGS.—1, H. Clay. 2, J. Oliver. 3, J. B. Braithwaite. CHICKENS.—Pure Breed.—1, J. White. 2, Rev. J. G. Raw. 3, J. Deighton. Cross Breed.—1, G. Carter. 2, Wetherill & Rickatson. 3, W. Bearpark. SELLING CLASSES.—Turkey or Goose.—1, F. Woodhouse. 2, J. Arrowsmith. 3, Mrs. G. Oliver. Ducks or Fowls.—1 and 3, Wetherill & Rickatson. 2, J. Clayton.

JUDGE.—Mr. E. Hutton, Pudsey, Leeds.

RIPON SHOW OF POULTRY, &c.

The third annual Show was held at Ripon on the 19th and 20th inst. in the Rifle Drill Hall. The judging, especially in the case of Pigeons and Cage Birds, had to be done by gaslight. Aquatic birds and Turkeys had the best light, as they were arranged in a spacious tent, where the dressed fowls, eggs, and butter were placed.

Dorkings were very good, but the *Cochins* much better. Almost every pen received a mention in *Hamburgs*. *Game* were a very good entry, as also were the *Bantams*. The two Selling classes contained forty entries.

Pigeons were well-filled classes in all cases. Carriers.—First Black and second Dun cock; a capital Black hen was very highly commended. Pouters.—First a very large White cock, very fine in girth and in good play; second Blue, rather short of wing-marking. Barbs a moderate lot. One of the best classes in the Show was the Almond Tumblers, almost all noticed. First and special a well-marked cock, the second losing in ground colour only. Any other Shortfaces, first a grand Agate and second a Kite, several others well deserving prizes. English Owls very good, the winners Blue. Foreign, first a very handsome White. Turbits, the first and special went to a fine Blue, the second also of that colour, and almost equal in quality. Trumpeters very good. The Long-faced Tumbler class was a good one, nearly every pen well worthy of a prize. Nuns were almost every bird extensively trimmed, consequently many birds were passed. In Magpies Reds won both prizes. Jacobs were a very good lot, the first very small. Fantails were one of the best classes we ever saw, the winners being exceptionally good in both tail and motion. Dragons were not as good as we see at most shows, but the two winners were very good in head. In the Variety class a very handsome Red Fairy Swallow was first and a Blondinette second. The Selling classes were very large and good.

Of *Cage Birds* there was an excellent display of 150, almost every one receiving a notice.

Rabbits had only thirteen entries and these of no special note.

POULTRY.—BRAHMAS.—1, H. Beldon. 2, G. A. Eastwood. DORINGS.—1, T. Swales. 2, T. P. Carver. COCHINS.—1, Special, and 2, G. H. Proctor. SPANISH.—1, J. Powell. 2, J. Thresh. POLANDS.—1, H. Beldon. 2, Dr. Macrae. HAMBURGS.—Golden-spangled.—1 and Special, W. Dodson. 2, H. Beldon. 3, T. P. Carver. Silver-spangled.—1, G. Alderson. 2, Robinson & Jagger. Silver-pencilled.—1, H. Pickles. 2, Robinson & Jagger. Black.—1, Robinson & Jagger. 2, T. P. Carver. GAME.—Black or Brown Red.—1, H. Mason. 2, W. Milner. Any other variety.—1 and Special, F. Sale. 2, Holmes & Destner. Single Cock.—1, F. Sale. 2, R. Craven. GAME BANTAM.—1 and Special, Mrs. Sellers. 2, W. Rudd. BANTAMS.—Any variety.—1, E. J. Booth. 2, R. Henderson. Any other variety.—1, C. J. Young. 2, T. P. Carver. FRENCH.—1 and Special, J. Johnson. 2, J. Graham. ANY OTHER VARIETY.—1, H. Conliffe. 2, R. Hawkins. SELLING CLASSES.—Cock, Drake, or Gander.—1 and Special, T. P. Carver. 2, S. Lucas. Hens, Ducks, or Geese.—1, G. W. Henshall. 2, J. Sherwin. LOCAL CLASS.—Any variety.—1, J. Sherwin. 2, T. H. Foden. TURKEYS.—1, T. Parker. 2, I. Moorey. GESE.—1 and Special, G. Pounder. 2, C. Atkinson. DUCKS.—Aylesbury.—1, C. Atkinson. 2, H. Beldon. Rouen.—1, F. G. S. Rawson. 2, J. Newton. Any other variety.—1, H. Beldon. 2, G. Sadler.

PIGEONS (SINGLE BIRDS).—CARRIERS.—1, E. Beckwith. 2, H. Yardley. POUTERS.—1 and 2, E. Beckwith. BARBS.—1, J. Thresh. 2, E. Beckwith. TUMBLERS.—Short-faced Almond.—1 and Special, H. Yardley. 2, E. Beckwith. Any other variety Short-faced.—1, R. & J. Anderson. 2, J. G. Spendlove. Any variety Long-faced.—1, H. Yardley. 2, Maud & Scott. OWLS.—English.—1, J. Thresh. 2, T. H. Stretch. Foreign.—1, G. Alderson. 2, J. Booth. TURBITS.—1 and Special, G. Sadler. 2, G. Alderson. TRUMPETERS.—1, R. Woods. 2, Beckwith. NUNS.—1, H. Beldon. 2, R. S. Mager. MAGPIES.—1, R. Woods. 2, Beckwith. JACOBS.—Red or Yellow.—1 and Special, G. Alderson. 2, J. Sherwin. Any other colour.—1, T. Holt. 2, E. Beckwith. ANTWERPS.—1, H. Yardley. 2, J. Booth. FANTAILS.—1, E. Horner. 2, E. Beckwith. DRAGONS.—1, E. Mawson. 2, J. Booth. ANY OTHER VARIETY.—1, H. Beldon. 2, T. Rule. YOUNG BIRDS.—1 and Special, E. Horner. 2, W. Bamforth. SELLING CLASSES.—Price not to exceed £2.—Single.—1, Beldon. 2, E. Beckwith. Price not to exceed £5.—Pairs.—1, T. Holt. 2, Beldon. Price not to exceed £1.—Single.—1, J. Sherwin. 2, J. Marshall. Pairs.—1, E. Beckwith. 2, S. Hill. LOCAL CLASS.—1 and Special, T. Horsman. 2, R. Bland.

CAGE BIRDS.—CANARIES.—BELGIAN.—1, T. Scully. 2, Stevens & Tennisswood. NORWICH.—Yellow.—1, C. J. Salt. 2, E. Arnold. Buff.—1, C. Burton. 2, C. J. Salt. Even-marked Yellow.—1, C. J. Salt. 2, Hampton & Cleminson. Even-marked Buff.—1, C. J. Salt. 2, E. Arnold. etc. Hampton & Cleminson. YORKSHIRE.—Yellow.—1, W. Goodhall. 2, J. Waite. Buff.—1 and 2, G. Turner. etc. W. Goodhall. ANY OTHER VARIETY.—1 and Special, Hampton & Cleminson. 2, R. C. J. Salt. etc. R. Atkinson. LIZARD.—Golden-spangled.—1, Hampton & Cleminson. 2, W. Addison. Silver-spangled.—1, Hampton & Cleminson. 2, J. Wilkinson. etc. Stevens & Tennisswood, Hampton & Cleminson, W. Addison. GOLDFINCH MULE.—1, Stevens & Tennisswood. 2, C. J. Salt. CANARIES.—Cage of Six.—

1, G. Frank. 2, W. Addison. *Any variety, local class.*—1, R. Atkinson. 2, T. G. Wray. *who.* J. Waite, R. Atkinson, T. G. Wray. *Any other variety.*—1, T. G. Wray. 2, C. Burton. *who.* R. Atkinson, Stevens & Tenniswood. *ENGLISH BIRD.*—1, J. E. Powell. 2, R. Atkinson. *FOREIGN BIRD.*—1, Mrs. R. Williamson. 2, F. Barwick. *PARROT—Grey.*—1, H. Wescoe. 2, G. Strodger. *Any other variety.*—1, R. Pearson. 2, M. Appleton. *SELLING CLASS.*—1, Land Special, C. J. Salt. 2, Hampton & Cleminson.

RABBITS.—*LOP-EAR.*—1, T. & E. J. Fell. 2, J. Taylor. *ANY OTHER VARIETY.*—1, H. Lund. 2, J. W. Moses & Oscar.

JUDGES.—*Poultry:* Mr. J. Dixon. *Pigeons, Cage Birds, and Rabbits:* Mr. E. Hutton.

SOUTH LONDON POULTRY SHOW.

MR. HALL's third Show was held at the Great National Recreation Hall, Westminster Bridge Road, better known as the Lambeth Baths, on Thursday last and following days. The place is much better adapted for the purpose of a show than the Bermondsey Working Mens' Club, the building in which the Show was held last year. The object of the Show is, we believe, to give the working men of South London, who are unable to pay the large entry fees of the other London shows, an opportunity of exhibiting their specimens. The Secretary was, we believe, firm with regard to the objects, and would not kill "the goose that laid the golden eggs," and declined the entries of a large exhibitor, who would have doubtless carried all before him and left those for whom the Show was specially designed with a simple card for their entry fees. Many alterations could have been made that would have contributed to the comfort of the birds, but the suggestions have, we believe, been made to the Secretary, and if the Show is continued we believe an effort will be made to accomplish all that is desired.

Dorkings have so many requirements that London could hardly be expected to furnish the winners, which were nice birds, but we liked the third-prize much better; the hen in this pen was worth all the class. *Spanish*—This was a really fine class, and also the prizes went to London exhibitors, the first also obtaining the cup for best pen in Show. *Cochins* a fine lot; the winners nice White, a little creamy; second Buffs. Pen 22 we thought should have been in the prize list. *Brahmas* were not up to our expectations. *Game* a capital class. *Foreign*—We were at a loss to understand the term. *Houdans* first, but we did not like them; the cock's spurs were growing outside his legs. Pen 71 (highly commended) we thought much the best pen in the class.

The *Pigeons* were, as might have been expected, much better than the poultry, and they appeared well judged.

Rabbits were largely represented, and the quality marvellously good. The exhibitors here appeared also quite satisfied with the awards.

PRIZE POULTRY.—The fine collection of poultry bred by Mrs. Acton Tindal of Aylesbury was sold by auction on the 14th inst. by Messrs. Reader & Son. There was a large attendance of buyers. The following are some of the prices obtained:—A Buff Cochins cock, winner at the Crystal Palace Show in 1875, fetched £11 11s., bought for Lady Gwydyr. Lot 66 was a Partridge Cochins cock, which took the first prize at Aylesbury, first prize at Altrincham, and several other shows; it realised £5 5s. Several of the Partridge hens and pullets fetched £3 3s. each. A fine lot of White Cochins brought high prices. One prize cock was knocked down for £17 17s., and another for £13 2s. 6d.

RABBIT FEEDING.

No animal is so free from disease as the Rabbit when allowed to follow its instinct in the procuring of its food; but when shut up between four walls or four boards, and unable to eat tonic and other herbs which Nature has taught it are necessary for the preservation of health, its health is apt to be deranged. To prevent this it is necessary to keep Rabbits supplied with food of such a character as shall keep them in health. The bowels are easily deranged, so that care should be taken to guard against any danger in that respect. Too much dry food will cause constipation and skin disease, while an excessive supply of green food will relax the bowels and pull the animal down in health and strength. The quantity of each kind of food should be kept in proportion, and the whole should be regulated by the amount of exercise and the health of the recipient.

Passing over the directions for feeding young Rabbits and for fattening we will direct our attention to the proper supply of food to adult Rabbits, whether they are breeders or kept for exhibition. We have in a recent number given full instructions as to the best sorts of troughs to use, and a good selection of these articles will save much money and trouble. If ever the Rabbit refuses to eat great care should be taken to examine the troughs and see if anything is wrong there. If not, the mistake must have been made in the food, and a change should be tried.

Every keeper of Rabbits knows that there are two kinds of food—the dry and the wet. Rabbits are seldom treated to water. Sometimes a little water is given for a treat now and

then, and occasionally, but very rarely, a rabbitry is found where water forms one of the regular articles of diet. Advocates of water make a great point of the fact that wild Rabbits drink a great deal and are often seen near shallow pools. They forget two very important facts: First, a Rabbit when wild has much exercise, and can also eat herbs of a drying nature. Besides this, in damp weather dead Rabbits are often found in Rabbit warrens, and generally near water. If these are dissected it is generally found that their death has been caused by over-drinking. These circumstances should make the addition or provision of water the question of grave consideration, especially when it is borne in mind that not one in a hundred of the exhibition Rabbits ever tasted any. The only time that a little water is advisable is to a doe just before kindling. A little damp food may be given with advantage, and milk is better than water in that case.

The staple food should be dry grain, such as oats, barley, buckwheat, &c. Oats are good for muscle-producing, and at the same time keep the Rabbit in good condition. Barley is a little too much inclined to be hot to be given too often. It is more inclined to fatten than to strengthen, and should not be given to growing Rabbits. Buckwheat is good bruised. Oats are the cheapest food; they can be bought at from 4s. to 5s. per bushel, and a bushel will last a long time in a small collection. They should be given dry in a trough kept on purpose for dry food, so that there will be no smell, as the Rabbits are very sensitive on this point. Some Rabbits take very well to oats, and will take them before almost any dry food; others do not seem to care much for them. In order to make them more savoury it is as well, and in fact necessary, to adopt some kind of relish. Tea leaves are very popular with Rabbits, and are very good for a treat. If a handful is squeezed pretty dry and mixed with the feed of oats the whole will be eaten with great relish. In this case care should be taken that the two are well blended, or the oats will not get much eaten. This mixture should not be given in an open trough, or the Rabbits in hunting for the tea leaves will scatter the whole contents on the floor. A safety top such as that described in a late number should rather be adopted. Soaked bread is sometimes mixed with the oats and makes a good change. Barley should be given crushed or soaked. Bran and pollard are also very good for food; they can be bought very cheap and should be mixed with meal. A handful of meal, oat or barley, to three times the quantity of bran or pollard and mixed warm with water or milk will make a good occasional meal, though it is hardly to be recommended for a regular food. Barley meal is especially fattening, and should be used more for putting a Rabbit into condition than as a staple food. Bran alone is not good for food, being very light and tasteless.

If no liquid food is given to the Rabbits care should be taken to cater for their wants with herbaceous food. Turnips and carrots are very useful. Both the tops and the bottoms may be given. Turnips are very hot and should not form a large share of the diet, but carrots are both strengthening and may be given frequently. Scrape the dirt from the roots, and cut out any decayed portions. The tops may be given pretty freely. Cabbage stalks and leaves are very easily obtained and very good, the former especially. Lettuce, endive, parsley, chicory, and a score of other plants may be given at discretion. If the leaves are damp they are very apt to cause looseness; they should therefore be dried a little before using. Three times a day the Rabbits should all be supplied with food, which should be of different sorts so as to create an appetite. If any food is left in the trough it should be thrown away and the trough carefully washed. A little oilcake or a dry crust or two may be given at intervals for a change. Regularity in the times of feeding is also very important.—GETA.

DORSET POULTRY, PIGEON, AND CAGE-BIRD SHOW.—It will have been seen in our advertising columns that this is to take place on the 16th and 17th proximo. The prizes amount to £300, including thirty silver cups and pieces of plate.

BAR-FRAMED HIVES AND THEIR MANAGEMENT.

No. 2.

PRESUMING, then, that hives of wood are on every account the most handy, useful, and durable for all purposes of bee-keeping—proved to be so by the fact that ninety-nine out of every hundred educated bee-masters use them—I pass to the question of size and shape, as to which there is some variety of opinion. As to size I cannot alter the opinion I have formed after an experience of many years:—"Large hives for places rich in honey pasturage, smaller hives for localities badly furnished with nectar-producing flowers." A correspondent in a recent Journal thinks I have misunderstood Mr. Pettigrew's argument in favour of large hives everywhere and under all circumstances. I do not think I have done so, nor does his explanation convince me differently. No doubt a hive may be so very small as to limit injuriously the breeding powers of the queen, but I am

no advocates for a very small hive, nor ever have been. Taking Mr. Woodbury's average size as the minimum and Mr. Pettigrew's as the maximum, there will be no perceptible difference in the population of those hives when autumn is over, supposing them to have started fair in the spring with queens of equal power and bees and food in equal proportions, also supposing that they are treated exactly alike. They will start alike the following spring (errors and mishaps allowed for), and the harvest will be according to the supply, and likewise the consumption of food will be more or less according to the population. A very large hive with a very large population no doubt gathers more honey than a smaller hive with a less population; but then also it will consume honey in proportion, and in bad seasons, or where there is unfavourable pasturage, it will often starve where the other will live and thrive, not to speak of the tendency of bees to make an excess of comb, which will be favourable certainly to a large development of brood, but which will as certainly cause a wasteful consumption of honey in the process of unnecessary wax-formation.

Not many weeks ago one of your correspondents gave some account of what may be called a telescope hive. Being large in itself it was so constructed as to admit of contraction in autumn by means of dummy slides or partitions. I have just constructed one of these to carry sixteen bars. It is of exactly the same width and depth as the ordinary bar hive of Mr. Woodbury. The only difference is in its length, which obviously can be extended *ad libitum*. I do not think I have exactly hit the proper length for the admission of the additional six bars as described by your correspondent. On examination I find my hive to be $22\frac{1}{2}$ inches long, inside measurement. Here then is a hive which might be called "the peacemaker," as it combines the two contending principles and allows scope for the working of each under varying circumstances of years and pasturage. I mean to give it a fair trial during the approaching summer, and have no doubt whatever as to its meeting all the wants of the educated bee-keeper of century nineteen. It is plain to the simplest understanding that this hive can be enlarged to the fullest capacity of the Pettigrew lippen, and comb contracted to the smallest dimensions consistent with the safe working of even a weak cast.

The eight bars in the centre would suffice for winter storage and use, when the two ends marked off by the dummy partitions could be filled with shavings, so making the centre snug against severe frost. If the bees were exceptionally strong one of these partitions could be removed and space for twelve bars allowed to the bees. There is, moreover, ample room overhead for two large supers or almost any number of sectionals. Nor is it a mere speculation as to whether this hive is good or not. Its great success last year in so bad a season verifies literally the proverb "the proof of the pudding is in the eating."—B. & W.

BEES IN LONDON.

I do not understand bees, at least in the sense that skilled apianians understand them, but I admire their wonderful habits, their great industry, their sagacity and apparent intelligence. As a gardener I have tended them, cultivated them perhaps I may say, for their honey, the same as I have grown trees for their fruit; but trees I confess have received much more of my attention than bees. I have never killed the trees when gathering their fruit, but I have, with pain and regret, assisted to kill thousands of bees when gathering their honey. But that cruelty belongs to the past, and I have not indulged in a practice so relentless and rude since I commenced reading your pages. From the bee department of the Journal I have, like other gardeners, derived many a valuable hint and have had many an hour's pleasure in reading. From the poultry pages, too, I could not only tell that I have derived enjoyment but profit, for the putting into practice the advice therefrom gained I have had the reward of hard cash, which my henwife has duly appreciated. But I am wandering. My object in writing is to admit what I feel is a shortcoming on my part, for although I have been entertained and benefited by reading about poultry and bees, I have not in return attempted to entertain others. I have never before written a line on bees, and I am not sure that the present effort will not exhaust me; and I should not have written now had I not met with a surprise during the past summer of a kind that I do not remember to have seen published.

When we read about localities being unsuited for bees, of bad feeding grounds, and deterrent observations of that nature, an idea is fostered, I think, that our honey-gathering friends can only exist profitably on the purple heather-clad hills and amid fields of white clover. But is not the tone of such suggestions as we occasionally see rather a reproach on the bee-keeper—or killer, than on the bees? I think so. Bees, I am of opinion, will thrive almost anywhere if their owners will exercise the same amount of intelligence and industry that are displayed by the "insects." At any rate I know they will prosper in London, which suggests that they will increase and multiply,

and will store up honey in other places similarly destitute of clover and heather. When I refer to London I do not mean the suburbs, but a central and one of the most busy parts of the metropolis. Within a stone's throw of the north-west end of Charing Cross Railway Station in the Strand—that is, if you can throw high enough, is a small but flourishing apiary. The topmost room of one of the lofty buildings there contains birds and bees; it is, in fact, an aviary and apiary combined. The owner, who has a considerable business there, has a fancy for bees and for birds, which he personally attends to, and the results are highly gratifying. It was by the courtesy of an assistant that I was permitted to inspect these thriving London bees. I happened to attend on the day that a super had been taken from one of the hives—a splendid super of London-stored honey, yet bright and clear, which could not have weighed less than 85 lbs. The bees are kept inside the room and close to the window, which is closed with the exception of an aperture at the bottom of the sash for their egress and ingress. They go in streams across the Thames and return laden with the results of their smoky expedition. Where their feeding ground is it is not easy to determine, but it is certain that it is not on the heather nor among the clover.

The super was removed to a lower room when the door was closed, and the window was opened for the escape of the stray bees. They found their way out satisfactorily enough, but the assistant thought their movements rather slow. At every casual examination he found bees in the room, until at length he thought it rather "queer," and he examined more closely, and was not a little amused to find a continual stream of bees as busy as bees could be carrying back the honey from the super below to the parent hive above. London bees he thought were as "cute as London boys—always on the look-out for themselves." Their "little game" was stopped, and a fine take of London honey was secured by the loss of little more than a dozen bees.

This little narrative may perhaps interest your utilitarian bee-keeper Mr. Pettigrew, and may, perhaps, also encourage others who hesitate to keep bees because they have no clover. To my mind it proves how impediments vanish before intelligence and well-applied industry on the part of the bee-keeper, who, I think, is generally more to blame than the bees when failure occurs.—A COUNTRY GARDENER.

OUR LETTER BOX.

STOCK FOWLS (C. S.).—At this time of year, if all the eggs are required for sitting, a cock should not have more than four or five hens. In February he may have seven or eight, and in April and May a dozen. A cock of different blood would be desirable; but if the bird you have is in points preferable to any other you have in view we advise you to keep him for this year only. You need not fear any ill effects from the two cocks running with fourteen hens, but in May and June you would have to remove one of them. An 1875 cock would do well put with the pullets of last year, and that would enable you to put the young cock with the hens. The formation of walks in 1879, the different sexes being taken from the different runs, would probably be very successful.

FOWLS HARD-CROPPED (Constant Reader).—Give each a table-spoonful of castor oil.

METEOROLOGICAL OBSERVATIONS.

THE usual "meteorological observations" not having arrived at the time for going to press their publication must be postponed until next week. The temperature in London has been considerably lower during the last few days than previously, and there was a slight fall of snow yesterday (Wednesday) morning—the first snow of the winter.

COVENT GARDEN MARKET.—DECEMBER 26.

BUSINESS, as is usual immediately after Christmas, is by no means brisk, and there is no quotable alteration in prices.
